**Parasites of horn fly and other flies breeding in dung, A. W. LINDQUIST** (*Jour. Econ. Ent.*, 29 (1936), No. 6, pp. 1154-1158).—In the course of the studies of parasites and predators of blowflies at Uvalde Tex., *Spalangia muscidarum stomoxysiae* Gir. and *S. drosophilae* Ashm. were found to be attracted to dry or partly dry cattle droppings. *S. muscidarum stomoxysiae* attacks pupae of *Sarcophaga*, *Cryptolucilia*, the horn fly, and the housefly in and under cattle droppings. *Spalangia drosophilae* parasitizes small dipterous pupae but will also attack the horn fly. The average developmental period of *S. muscidarum stomoxysiae* was 22.8 days during the spring and summer, with a daily mean temperature of 83.1° F. Adult longevity was as much as 25 days with *S. muscidarum stomoxysiae* and 31 days with *S. drosophilae*. The percentage of parasitization by *Spalangia* was determined by collecting and segregating the dipterous pupae in and under cattle droppings. In 67 field droppings 14.6 percent of the *Sarcophaga* and *Cryptolucilia* that migrated and 43.8 percent of those that remained in the manure were parasitized by *Spalangia*. With the horn fly 38.2 percent of those that migrated and 64.3 percent of those in the manure were parasitized. Over 95 percent of the *Spalangia* were *S. muscidarum stomoxysiae*. A staphylinid beetle, *Baryodma bimaculata* Grav., accounted for a parasitization of 24.9 percent of the *Sarcophaga* and *Cryptolucilia*. In a series of 96 artificial patches of cow dung infested with horn fly, a total parasitization of 15.1 percent by *Spalangia* occurred. *S. muscidarum stomoxysiae* is considered to offer possibilities as a means of biological control of the horn fly, its habits being favorable to artificial propagation.

**Preliminary tests with liquid bait in Japanese beetle traps, F. W. METZGER, W. E. FLEMING, E. G. REX, and W. W. MAINES** (*Entomol. Log.*, 4 (1936), No. 7, pp. 16, 17, fig. 1).—Tests of geraniol (10 parts) and eugenol (1 part), vaporized by means of a wick inserted in a bottle containing the attractants, made with a view to devising a bait which will maintain maximum attractiveness for the Japanese beetle over a considerable period of time (several weeks), have been promising. The results indicated that when certain sized wicks were used in two types of traps more beetles were captured than in check traps containing the bran-molasses bait with the attractants added.

**On the first instar larvae of some species of Otiorrhynchus found on strawberries, with notes on their biology, J. H. FIDLER** (*Bul. Ent. Res.*, 27 (1936), No. 3, pp. 369-376, figs. 4).—A report is made of studies undertaken to

discover some practical means of identification of newly-hatched larvae of the black vine weevil, *O. rugosostriatus* Goeze, the strawberry root weevil, and *O. rugifrons* Gyll.

**Field movement of boll weevils in relation to initial infestation and rainfall.** G. L. SMITH and M. T. YOUNG (*Jour. Econ. Ent.*, 29 (1936), No. 6, pp. 1063-1066, fig. 1).—A comparison of bollweevils in movement, as recorded on screens at Tallulah, La., from 1933 to 1935, shows a positive correlation between the number of weevils taken and the total rainfall over the corresponding period. It also indicates a positive correlation between the number of weevils taken and the number of days with 0.3 in. or more of rainfall.

**Boll weevil activity during normal hibernation period at Tallulah, La.** R. C. GAINES (*Jour. Econ. Ent.*, 29 (1936), No. 6, pp. 1096-1099, fig. 1).—Observations during 1928-29 and from 1930-31 to 1934-35 here reported have shown that a surprisingly large number of bollweevils become active during the normal period of hibernation. Under artificial cage conditions 1 percent of the total bollweevil activity occurred when maximum temperatures ranged from 36° to 45° F. The screen records indicated that maximum temperatures of 62° or higher are necessary before actual flight takes place.

**Western rose curculio *Rhynchites bicolor wickhami* Ckl., J. L. HOERNER** (*Colorado Sta. Bul.* 432 (1936), pp. 19, figs. 6).—The western rose curculio *R. bicolor wickhami* is one of the most destructive pests of wild and cultivated roses in Colorado, even a few beetles being capable of destroying the entire crop of roses on small bushes by their punctures in the buds or in the stems below the buds. It does not so readily attack the climber and rambler roses, but feeds on these and on raspberry buds in rearing cages when no other food is available. In addition to the egg punctures, the female will puncture the stem of the bud so that it will wilt and usually bend over and dry, leaving the mummified bud in which the larva develops. A pair of beetles in rearing cages have made as high as 99 punctures in rosebuds in 24 hr.

Technical descriptions are given of its several stages and a summary of information on its life cycle. The larvae pass the winter in the soil, pupate in April or early May, transform to adults in about 9 days, and emerge from the soil 2 weeks later. The eggs, of which some 40 are deposited by each female, hatch in about 10 days. The larvae feed inside the dry rosebud, leaving it to enter the ground. There is one generation a year.

A single ichneumonid larval parasite, *Temelucha* sp., was found associated with it, but not in numbers sufficient to check the development to any great extent. The results of work with insecticides on caged beetles are presented in detail in table form. Hand picking of the beetles as they appear on the rosebuds did not prevent serious injury, but hand picking of the buds and destroying them, thus preventing development of the larvae, was found to give protection the following year. The best control of the beetle has been obtained by the use of calcium arsenate applied as dust to the foliage of the plants. Carbon disulfide emulsion, 0.35-percent strength, applied at the rate of 1 qt. to a square foot, gave good control of the overwintering larvae.

**New injurious Curculionidae (Col.) from South America.** G. MARSHALL (*Bul. Ent. Res.*, 27 (1936), No. 3, pp. 497-501, figs. 3).—*Premnotypes fractirostris*, reared in England from potatoes received from Peru, *Hypsonotus parceguttatus* and *H. modestus*, both attacking leaves of cacao in Brazil, and *Acallestes camelus*, attacking leaves and fruit of cacao in Brazil, are described as new.

**Effect of reduced temperature and pressure upon honeybee respiration.** C. E. WOODWORTH (*Jour. Econ. Ent.*, 29 (1936), No. 6, pp. 1128-1132, figs. 2).—The author reports upon work conducted in continuation of that previously noted (E. S. R., 68, p. 361). It is pointed out that within ordinary

ranges of temperature, from 20° to 25° C., there is a zone of comfort in which standard metabolism is fairly constant. Above and below that point an irritation metabolism sets in which is physically recognized among honeybees by increased muscular activity and fanning. At low temperatures, 10°, for example, a numbing is experienced, with low metabolism as a consequence. Reduced pressure in the numbed condition in general reduces metabolism. Extremely low pressures bring in another factor, perhaps evaporation, which slightly increases carbon dioxide output. There is at first, in cases of reduced pressures, an increase in metabolism which later wears off. This may be called the compensatory metabolism, after which the real reduced pressure effect reveals itself which is found to be a reduced metabolism.

**The organism of European foul-brood of bees,** H. L. A. TARR (*Nature* [London], 137 (1936), No. 3456, pp. 151, 152, fig. 1).—During the course of work at the Rothamsted Experimental Station (E. S. R., 75, p. 385) on the etiology of European foulbrood, a detailed study was made of 10 strains of *Streptococcus apis* isolated from affected larvae from a number of different cases of this disease.

These cultures could be divided into two groups, one of which caused the rapid and complete liquefaction of gelatin and coagulated and peptonized the casein of milk, the other leaving these proteins apparently unchanged. Four of the strains examined fell into the first named group, and 6 into the other group. In all other respects these strains were identical. Morphologically they were indistinguishable, and all gave identical fermentation reactions. Thus, all formed acid from dextrin, sucrose, lactose, maltose, glucose, fructose, galactose, mannose, mannitol, glycerol, and salicin, and none of them produced acid from starch, inulin, raffinose, arabinose, xylose, inositol, adonitol, and erythritol under the experimental conditions.

**On the control of household ants,** H. W. THOMPSON and L. R. JOHNSON (*Bul. Ent. Res.*, 27 (1936), No. 3, pp. 393-397, fig. 1).—The authors have used a thallium sulfate syrup as a poison bait with success against Pharoah's ant and *Acanthomyops* (*Donisthorpea*) *niger*, and conclude that this inexpensive method is likely to prove useful in places where it is not practicable to find and destroy the nest.

**A new species of Habrolepis parasitic in Chrysomphalus aurantii** Mask, H. COMPERE (*Bul. Ent. Res.*, 27 (1936), No. 3, pp. 493-496, fig. 1).—Contributing from the California Citrus Experiment Station, an account and description are given of a new parasite of the California red scale reared in the Transvaal, Union of South Africa, under the name of *H. rousi*.

**On the biology of Emphytus cinctus, L., and Blennocampa waldheimi, Gimm.** (Hym., Symphyta), H. W. MILES (*Bul. Ent. Res.*, 27 (1936), No. 3, pp. 467-476, pls. 2, figs. 2).—This contribution relates to two sawflies (the curled rose sawfly and *B. waldheimi*) found to be of economic importance in Britain, where the first mentioned is an enemy of the rose and both attack the strawberry.

**A new pecan sawfly, Megaxyela langstoni n. sp.** (Hymenoptera: Xyelidae), H. H. ROSS (*Ent. News*, 47 (1936), No. 5, pp. 131, 132).—A sawfly reared from the pecan at the Mississippi Experiment Station is described as new under the name *M. langstoni*.

**Observations on bulb scale mite as a major pest of narcissus,** C. F. DOUCETTE (*Jour. Econ. Ent.*, 29 (1936), No. 6, pp. 1103-1105).—Observations of the bulb scale mite here reported upon have shown it to be one of the major pests of narcissus. Thermal treatments are the only dependable methods of control at present. Submerging the bulbs in warm water at 110° F. for 1 hr.

effects complete mortality of all stages, with sufficient margin to allow for any variations which might occur in large quantity treatments. Vapor heat treatment will also effect complete mortality when used for 2 hr. at 110°-111°. In both methods the period of treatment is exclusive of the time required for the bulbs to reach the treatment temperature. These treatments are best used for planting stock from which bulbs are to be selected for sale the following season. Bulb producers who have been following a general thermal treatment program for their stocks have experienced little trouble with this mite.

**Biology and economic importance of the Gulf coast tick, F. C. BISHOPP and H. HIXSON** (*Jour. Econ. Ent.*, 29 (1936), No. 6, pp. 1068-1076, figs. 2).—A study is reported of the Gulf coast tick, which since the screwworm (*Cochliomyia americana*) invasion of the Gulf States eastward of Louisiana has assumed an economic importance second only to the cattle tick. This is due particularly to its attachment to and wounding of the inner surface of the ear of various animals.

**Starvation record set as ticks survive for five years** (*Sci. News Letter*, 30 (1936), No. 812, pp. 278, 279, figs. 2).—In the course of work with relapsing fever of man, specimens of *Ornithodoros turicata* collected in Texas were alive at the end of 5 yr. of confinement in the laboratory, at which time they fed upon and transmitted spirochetes to their monkey host.

## ANIMAL PRODUCTION

**The mechanical aspect of the nutrition of farm stock, E. J. SHEEHY** (*Roy. Dublin Soc. Sci. Proc., n. ser.*, 21 (1936), No. 29, pp. 257-280).—This study involved a series of 13 paired feeding trials with young pigs, in each of which a well-balanced ration of corn meal, barley meal, meat meal, and salt was compared with a ration of similar nutritive value in which a portion of the grain was replaced by one or more ingredients in an attempt to improve the ration from the standpoint of its mechanical action on the digestive tract.

In all trials, the concentrated basal ration exerted a costive effect and the pigs failed to consume an optimum quantity. Replacing an equivalent amount of the grain in the ration with 20 percent of linseed meal or from 10 to 20 percent of wheat bran increased the appetite of the pigs, improved the character of the feces, and enhanced the value of the ration. Ground oats did not exert a like favorable influence on the concentrated ration, although the substitution of oats for corn in the absence of bran or linseed meal did not lower the nutritive value. The addition of linseed meal to a ration containing 25 percent of wheat bran did not improve its value. The substitution of oats for corn in a ration containing bran or linseed meal showed oats to be decidedly inferior to corn under these conditions. The addition of carrageen moss or paraffin oil to a very concentrated ration improved the character of the feces and caused the pigs to be less restive. However, the effect gradually diminished and eventually decreased the appetite of the animals. The addition of green feed to the concentrated ration proved it to be equally as effective as either bran or linseed meal as a source of bulk and also a valuable source of vitamin A.

The author gives an extended discussion of the mechanical action exerted by different types of feed in the digestive tract, and points out the need for distinguishing between those feeds which supply bulk merely through their high fiber content as contrasted with those feeds which exert a beneficial action within the intestines due to their lubricative action or to their water-holding or succulent qualities.

**Reproductive capacity of female rats as affected by kinds of carbohydrates in the ration.** C. H. WHITMAN and R. BOGART (*Jour. Agr. Res. [U. S.]*, 53 (1936), No. 7, pp. 527-532, pl. 1).—In this study at the Kansas Experiment Station, the experimental rations contained casein 20 percent, butter oil 20, starch 30 percent and (as an additional source of carbohydrates) either sucrose, lactose, or starch 20 percent, plus yeast, Osborne and Mendel salt mixture, and cod-liver oil. Female rats reared on these various diets were placed with fertile males at ages ranging from 48 to 80 days and were allowed to remain for 40 days or until pregnancy was detected.

The sucrose-containing diet proved inadequate for normal reproduction, only one female in this group producing a live litter and she was afterwards sterile. Precocious sexual development and extreme luteinization of follicles and persistency of corpora lutea were generally observed in this group. Changing these animals from the experimental rations to the regular stock ration during adult life did not restore their reproductive function. The ovarian abnormalities indicated that sucrose may have either directly or indirectly affected the activity of the pituitary. Animals fed the lactose- and starch-containing rations reproduced normally and had normal ovarian structures.

**The utilization of energy at different levels of protein intake.** S. R. JOHNSON, A. G. HOGAN, and U. S. ASHWORTH (*Missouri Sta. Res. Bul.* 246 (1936), pp. 62, figs. 6).—This bulletin presents results of eight series of paired feeding trials with growing rats on rations which contained amounts of protein adequate and inadequate for normal growth. In most cases three pairs of litter mates were used in a series, one pair being subjected to carcass analysis after a 3-day preliminary feeding period, one pair used for determining the digestibility of the ration, and the other pair for measuring the respiratory exchange using the Haldane open-circuit gas absorption train. Total feed consumption, total body weight gains, and composition of all carcasses at the end of the trial were also determined.

In each instance growth was more rapid on the reasonably high protein diet than on the like diet inadequate in protein. Digestibility of the food constituents, except protein, was practically identical for the high and low protein groups. The higher percentage protein digestibility in the high intake group is attributed to fecal metabolic nitrogen. Heat production averaged about 3.5 percent higher in the high protein group, while the higher respiratory quotient of the low protein group indicated a greater fat storage than for the high protein group. Carcass analyses showed that animals on high protein diets stored more water, protein, and ash and consequently less energy per unit of gain than their pair mates on low protein intake which stored more fat, hence more energy per unit of gain. The net utilization of energy for body gain by all animals was adjudged the same. The adaptability of the paired feeding technic to various types of nutrition research is discussed in the light of these findings.

**An improved synthetic ration for vitamin B<sub>12</sub> studies.** O. L. KLINE, H. R. BIRD, C. A. ELVERJEM, and E. B. HART (*Jour. Nutr.*, 11 (1936), No. 6, pp. 515-528, fig. 1).—This study at the Wisconsin Experiment Station relates to the incidence of nutritional paralysis in chicks due to vitamin B<sub>12</sub> deficiency as previously noted (*El. S. R.*, 71, p. 364). It is shown that failure to consistently produce evidence of vitamin B<sub>12</sub> deficiency in chicks under experimental conditions is largely due to the presence of this factor in various constituents of the synthetic diet. This revised method of study prescribes the use of a diet designated as ration 452. The principal changes in this diet over those previously used include (1) purification of the casein by dissolving crude casein in dilute

ammonium hydroxide, reprecipitating with dilute hydrochloric acid, and washing with distilled water, this process being repeated three times before drying the precipitate; (2) the use of highly potent sources of the factors in the vitamin B complex other than B<sub>4</sub>; and (3) the inclusion of 2 percent of water-extracted dried lung tissue as a potent source of the "gizzard factor." Nutritional paralysis occurred in 100 percent of the chicks on this improved basal synthetic ration. Supplements of 15 percent of dried brain tissue, dried kidney tissue, or peanuts replacing an equal percentage of dextrin in the diet supplied ample B<sub>4</sub> for normal development.

The authors sum up the problem in these words: "Although we speak of ration 452 as one for the production of vitamin B<sub>4</sub> deficiency, it is impossible to conclude that it is complete in all other factors. We know that the addition of 15 percent peanuts, brain, or kidney as sources of vitamin B<sub>4</sub> will produce normal chicks. We have also had fair success with certain B<sub>4</sub> concentrates, but until normal chicks are reared on ration 452 plus pure vitamin B<sub>4</sub>, the possibility of still other factors must be considered. We also want to emphasize that ration 452 may not be a perfect ration for B<sub>4</sub> assay. Many improvements may be made in the future, but it is the best available at present."

**The distribution of vitamin B<sub>4</sub> in some plant and animal products, O. L. KLINE, H. R. BIRD, C. A. ELVEHJEM, and E. B. HAET (*Jour. Nutr.*, 12 (1936), No. 5, pp. 455-460).**—Following the plan for producing vitamin B<sub>4</sub> deficiency in chicks as described above and employing the depleted chicks as test animals, the authors have determined the vitamin B<sub>4</sub> potency of a considerable number of both vegetable and animal products. The results of these assays are presented in tabular form. Dried grass, peanuts, wheat germ, pork brain, and pork kidney were found to be relatively good sources of the factor. The grains were found to be relatively poor sources, although white corn and hulled oats proved definitely superior to wheat and yellow corn.

**[Livestock investigations in Colorado] (*Colorado Sta. Rpt. 1936*, pp. 12, 15).** Results are briefly reported on the use of different supplements to North Park hay for wintering beef calves; and mineral and protein supplements for fattening lambs.

**[Experiments with livestock in Texas] (*Texas Sta. Rpt. 1935*, pp. 9, 10, 18, 20, 21, 23, 24, 35, 37-41, 42, 117-119, 122-124, 146, 147, 149-151, 200, 201, 204, 205, 219, 220, 230, 231, 232, 233, 234, 240, 241).**—Beef cattle investigations, reported by J. M. Jones, J. H. Jones, P. R. Johnson, R. A. Hall, J. J. Bayles, R. E. Dickson, E. K. Crouch, F. E. Keating, R. H. Stansel, J. H. Knox, H. Schmidt, W. H. Dameron, I. B. Boughton, W. T. Hardy, and O. L. Carpenter, include a study of the mineral requirements of cattle in various sections of the State, Sudan grazing v. Sudan grazing and cottonseed meal, vitamin A requirements in wintering rations, ground cotton burs v. cottonseed hulls in the ration, rice bran in the concentrate ration for fattening beef calves, the rate of fattening of individually fed and group-fed steers and the relationship of type and individuality of steers to rate and economy of gain, the adaptability of Herefords to east Texas, the value of sugarcane bagasse, the need of protein supplement on east Texas pastures, and native and improved pastures in the Gulf Coast prairie.

Sheep and goat studies, reported by J. M. Jones, B. L. Warwick, Dameron, D. A. Spencer, S. P. Davis, Boughton, Hardy, Carpenter, and F. B. Matthews, include the adaptation of Corriedale sheep to southwest Texas conditions, the relation of skin folds to weight of fleece on Rambouillet sheep, grades and shrinkages of Texas wool and mohair, the relation of age of animals to fineness of wool and mohair type, crutching or tagging of bred Rambouillet ewes, the value of bonemeal and cottonseed meal in the salt lick of breeding ewes, and

the occurrence of the deficiency disease called jimnies in sheep and goats which apparently is prevented by including cottonseed cake and bonemeal in the ration.

In swine studies results are reported on rice and rice byproducts for growing and fattening pigs, the average daily gains and feed requirements for pigs, Sudan grass and oat pastures for fattening pigs, the calcium requirement of pigs on grain rations balanced with cottonseed meal, and self-feeding brood sows, all by F. Hale; the effect of vitamin A-deficient rations on embryonic eye development in pigs, by Hale and Schmidt; methods of storing sliced cured bacon in oils, by S. Cover and Hale; and curing and storing pork in west Texas, by Hale, R. W. Snyder, and D. L. Jones.

Poultry studies, under the leadership of R. W. Sherwood, G. S. Fraps, and J. R. Crouch, yielded information on the requirements of chicks for vitamins A and D, the vitamin or curative material which prevents slipped tendon and favorably affects the condition of the plumage in chicks, the productive value of feeds as determined by slaughter experiments, the calcium and phosphorus requirements of chicks, and the mineral requirements for commercial chicken and turkey feeds.

Data are reported on the yield and nutritive value of spineless cactus (*Opuntia ellisiana*), by Dameron and Carpenter. Chemical studies of feeding stuffs, by Fraps and F. D. Fuller, yielded information on the mineral and vitamin content of commercial feeds, the value of low grade feeds, and the need for iodine in Texas feeds and foods.

The determination of the apparent digestibility of green and cured grass by modified procedures, J. C. KNOTT, H. K. MUEER, and R. E. HODGSON (*Jour. Agr. Res. [U. S.]*, 53 (1936), No. 7, pp. 553-556).—In trials at the Washington Experiment Station, a modified method of determining apparent digestibility was compared with the standard method in 6 digestion experiments with 17 sheep. The modified method consisted in determining the ratio of the amount of a given food substance to the amount of iron in the feed and feces. The iron balance for the different sheep varied from a retention for the 14-day period of over 20 percent of the iron ingested to an iron content of the feces of over 40 percent in excess of that ingested. The apparent digestibility calculated by the modified method varied significantly both above and below that obtained by the standard method. The variations obtained in iron balances and apparent digestibility by the modified method indicate that the use of this method is not justified in the case of ruminants.

A comparison of the chemical composition of pasture grass with a mixed concentrate, E. BENNETT (*Jour. Dairy Sci.*, 19 (1936), No. 9, pp. 623-629, figs. 2).—This study at the Massachusetts Experiment Station has shown that fertilization of pasture results in an increase in the protein and ash and a decrease in the crude fiber and nitrogen-free extract content in the dry matter of the grass. No significant differences were noted in the feed constituents, except that the fertilized grass contained a higher percentage of sucrose and a correspondingly lower hemicellulose content. The dry matter of the fertilized grass and a concentrate mixture, respectively, contained 18.4 and 19.4 percent of crude protein, 23 and 7.7 crude fiber, 3 and 5.4 ether extract, 45.9 and 60.2 nitrogen-free extract, and 9.6 and 7.2 percent of ash. The nitrogen fractions were very similar in the protein of each feed, each containing over 90 percent of protein nitrogen and with no traces of nitrate nitrogen occurring in either. The higher fiber content of the grass is due to the large amount of cellulose, the lignin content being only 1.75 percent greater than in the concentrate. The concentrate was characterized by a relatively higher percentage of sugar and starch. These results demonstrate that the dry matter content

of pasture grass in a vegetative state is comparable to a concentrated feed, and in the case of fertilized grass it closely approaches a nitrogenous concentrate in feeding value.

The composition and apparent digestibility of the flat pea (*Lathyrus silvestrus Wagneri*), R. E. HODGSON and J. C. KNORR (*Jour. Dairy Sci.*, 19 (1936), No. 8, pp. 531-534).—Trials conducted at the Washington Experiment Station showed flat pea hay harvested in the late-bloom stage to contain 82.9 percent dry matter which was 60.3 percent digestible. The percentage in the dry matter and the digestibility coefficients of the various constituents were, respectively, as follows: Crude protein 25.3 and 78.3, crude fiber 29.8 and 41.9, ether extract 2.2 and 45.8, nitrogen-free extract 36.6 and 65.2, and ash 6 and 51.6. ~~As~~asmuch as the hay was readily consumed without waste, it may be ranked as a palatable and highly nutritious forage.

The protein content of soybean hay, L. E. THATCHER and J. B. PARK (*Ohio Sta. Bimo. Bul.* 183 (1936), pp. 131-136).—This report presents data on the relative amounts of the soybean plant of the Manchou and Peking varieties represented in the leaves, the stem and pod, and the seed, and the protein content of each fraction harvested at five different stages of maturity. The most notable features of these results were the pronounced decrease in the proportion of leaves and the marked increase in the proportion of seed and also a slight increase in the proportion of stem and pod as the plants mature. The protein content declined gradually in the leaves and showed a very pronounced drop in the stem and pod, but remained rather constant in the seed as the plants approached maturity. The relation of these data to the choice of varieties and the proper stage for harvesting are briefly discussed.

Further studies on vitamins in alfalfa hay, C. E. VAIL, J. W. TOMISKA, and E. DOUGLASS (*Colorado Sta. Tech. Bul.* 18 (1936), pp. 19).—Reporting further investigations (E. S. R., 69, p. 839), this phase of the study deals with the effect of rapid artificial drying, drying in artificial light, green crushing and drying, and manner and length of storage on the content of vitamins A, B, and G in alfalfa hay, and the comparative vitamin content of common, Cossack, Turkestan, and Grimm varieties of alfalfa.

Results of vitamin A studies indicate that the usual methods of curing and stacking, exposure to ultraviolet light in the presence of moisture, and storage of alfalfa meal in cloth bags, each led to extensive loss or inactivation, while curing indoors, rapid artificial drying, crushing and rapid drying, and also storage of hay in the bale and storage of alfalfa meal in paper bags were effective means of conserving this vitamin. All varieties studied carried more vitamin A in the third cutting and all varieties contained similar quantities for a given cutting, except third cutting common which averaged considerably less than the other three varieties. In all cases vitamin A activity decreased with increasing length of storage.

Vitamin B studies indicate that alfalfa has a relatively low content of this factor (1 to 3 units per gram). Prolonged storage and other harsh treatments caused deterioration or total destruction of this factor. The small differences in the content of different varieties slightly favored the common.

Vitamin G studies show a content of from 3 to 5 units of this factor per gram of fresh Colorado alfalfa. Artificial drying was not harmful to this factor and crushing caused an apparent increase in activity, while some evidence of destruction was noted in top-weathered hay from stacks. No significant differences due to variety were found.

Commercial feeding stuffs, 1935-36, E. R. TOBEY (*Maine Sta. Off. Insp.* 160 (1936), pp. 19-70).—This is the usual report of the analyses for protein, fat,

and fiber of 950 samples of feeding stuffs collected for official inspection during the year ended June 30, 1936 (E. S. R., 74, p. 678).

**Inspection of commercial feeding stuffs, 1936,** T. O. SMITH and H. A. DAVIS (*New Hampshire Sta. Bul.* 292 (1936), pp. 59).—This is the usual report of the guaranteed and actual analyses of 384 brands of feeding stuffs collected for official inspection during the year ended June 1936 (E. S. R., 74, p. 678).

**Speeding-up beef feeding,** W. G. R. PATERSON (*Farmer and Stock-Breeder and Agr. Gaz.*, 50 (1936), No. 2441, p. 1725, figs. 3).—In a brief report of beef cattle feeding trials at the West of Scotland Agricultural College, it is shown that the overfeeding of concentrates may frequently occur, resulting in excessive costs per unit of gain.

Two uniform lots of cattle were compared over a 12-week feeding period. The animals in lot 1 were started at 6 lb. of concentrates daily and gradually increased to 8.5 lb., while those in lot 2 started at 8 lb. and increased to a maximum of 10.5 lb. Liberal allowances of swedes, hay, and straw were fed in addition. The average daily gain per animal was 2.6 lb. and 2.5 lb. for the two lots, respectively. In a second similar trial a group started at 5 lb. daily and increased to a maximum of 7.5 lb. made as rapid daily gains as the lot receiving from 6 to 8.5 lb.

In another trial sprouted corn which had reached a height of from 6 to 9 in. was fed to replace approximately 20 lb. of swedes (on dry matter basis) in the ration of fattening cattle. The animals in this lot made an average daily gain of 3.1 lb., with evidence that the sprouted corn exerted a pronounced beneficial effect on the utilization of the remainder of the ration.

**The weights of the carcass and of the individual organs in the body of cattle in Kenya Colony,** M. H. FRENCH (*Empire Jour. Expt. Agr.*, 4 (1936), No. 14, pp. 108-115, pl. 1).—This contribution presents data on the live weight and the actual and proportional distribution of weight in the body of zebu cattle of Kenya and Tanganyika Territory in comparison with that of cross-bred zebu-European cattle and also with the average of the common British and American breeds. The significance of these data in relation to the suitability of zebu cattle for beef production is discussed.

**The occurrence of a britch-poll fibre-type array gradient in the New Zealand Romney lamb,** N. GALPIN (*Empire Jour. Expt. Agr.*, 4 (1936), No. 14, pp. 116-128, figs. 5).—It has previously been recognized that definite fiber-type arrays occur on different parts of the body coat of lambs, and the probable cause of fiber-type arrays has been postulated (E. S. R., 74, p. 379). This study was undertaken to determine whether or not an orderly relation exists between the fiber-type arrays occurring on different parts of the body. Romney lambs and also a limited number of Ryeland and Southdown lambs were included. Wool samples were taken from 15 different points on the body, and each sample was sorted according to a given classification of the fiber groups.

Based on the extent to which the fiber-type arrays were depressed, it is shown that there is a general gradient from britch to poll, i. e., a posterior-anterior gradient. This gradient is gradual and orderly, there being no sudden transition of array types in adjacent areas. There is also a gradient up the sides of the body which is subsidiary to the posterior-anterior gradient, the areas of least depression invariably occurring on the britch. The degree of medullation in the coat fiber was associated with the type of fiber array occurring, being most prevalent in those coats where the fiber areas were only slightly depressed and occurring less frequently where the areas were more depressed. Some medullation was observed in all Romney coats and to some extent in Ryelands but was negligible in the Southdown breed.

**The heat production of the sheep and the pig before and after castration, E. G. RITZMAN, N. F. COLOVOS, and F. G. BENEDICT (*New Hampshire Sta. Tech. Bul. 64* (1936), pp. 24).**—The authors have determined the effect of castration upon the respiratory metabolism of 6 normal, healthy male sheep and 1 normal, healthy male pig. Five of the sheep were castrated at about 5 mo. of age, the remaining sheep at 1 yr., and the pig at 6 mo.

Pertinent data, including body temperature, heart rate, and heat production as computed from the gaseous exchange determined in open-circuit respiration chambers, are presented in tabular form and fully discussed. Castration of the sheep and pigs at the age of puberty and adolescence seemed to result in a decrease in energy needs of from 5 to 10 percent. Only an insignificant proportion of this decrease can be attributed to lessened muscular activity, the major part of the effect being attributable to the absence of the testicular hormones. It is suggested that the effect might be still greater in animals castrated after reaching maturity.

**The basal metabolism of the goat, E. G. RITZMAN, L. E. WASHBURN, and F. G. BENEDICT (*New Hampshire Sta. Tech. Bul. 66* (1936), pp. 23, figs. 2).**—The authors have determined the body temperature, heart rate, and gaseous exchange by use of open-circuit respiration chambers on 18 goats, including 10 adult does, 6 young does, 1 adult buck, and 1 young buck. In most cases the experiments were conducted with animals at rest, in a fasting state, and at environmental temperatures of from 20° to 28° C. Pertinent data are presented in tabular form.

The basal heat production per 24 hr. per kilogram of body weight was 22.2, 20.7, 24.8, and 30.4 calories for the adult buck, adult does, young buck, and young does, respectively. In comparison with other types of farm animals it is shown that the basal metabolism of goats (expressed as calories per 10  $w^{3/4}$ ) is consistently below that of horses, beef steers, dairy cows, swine, or sheep.

**Critical study of important factors in successful pig-keeping, C. P. McMEEKAN (*New Zeal. Jour. Agr.*, 52 (1936), No. 5, pp. 278-289).**—Based on an analysis of a large number of individual litter records in New Zealand, several factors are discussed in relation to the efficiency of pork production. These points include the importance of heavy litters; the relative importance of number and weight of pigs upon litter weights; the extent, nature, and importance of mortality; the effect of age of the sow; the effect of season of farrow; the influence of breed and strain; litter variation and the effect of size of litter and weaning weight; and the influence of management.

**Phosphorus requirements in the ration of growing pigs, C. E. AUBEL, J. S. HUGHES, and H. F. LIENHARDT (*Kansas Sta. Tech. Bul. 41* (1936), pp. 86, figs. 23).**—This bulletin presents the results of 3 experiments in each of which 3 similar groups of purebred Hampshire pigs were employed. All were castrated males and were placed on experiment immediately after weaning at about 9 weeks of age and averaging about 43 lb. in weight. The same basal ration, adequate in all respects except phosphorus supply, was fed throughout the experiments, each of which extended over a 24-week feeding period.

In experiment 1, lots 1, 2, and 3 (6 pigs each) received 0.15, 0.29, and 0.59 percent phosphorus in their rations, respectively, during the first 7 weeks of the trial and 0.18, 0.33, and 0.59 percent phosphorus during the remaining 17 weeks. Two pigs from each lot were slaughtered after 8 weeks, 2 others after 16 weeks, and the remaining 2 at the end of the trial. Data are presented on the condition of the carcasses, dressing percentages, relative size of the body organs, and bone analyses. In experiment 2, lots 4, 5, and 6 (6 pigs each) received 0.15, 0.23, and 0.3 percent phosphorus, respectively, throughout the trial, pigs being slaughtered at intervals as above. In experiment 3, lots 7, 8, and 9 (4, 3, and

3 pigs) received 0.23, 0.27, and 0.3 percent phosphorus, respectively, throughout the trial, no pigs being slaughtered until the end of the experiment.

Experiment 1 established the fact that 0.18 percent phosphorus in the diet is inadequate and results in marked symptoms of phosphorus deficiency, the most significant of which are (1) a subnormal level of inorganic phosphorus in the blood which averaged slightly over 3 mg per 100 cc; (2) subnormal growth, especially failure of the bones and muscle to develop normally; (3) decreased efficiency in utilization of feed and storage of energy, although the greater amount of feed required per unit of increase in body weight in the deficient group is partially offset by the fact that this group invariably stored a higher percentage of fat in proportion to body weight gain; (4) a pronounced decline in appetite; and (5) an increased thirst, causing pigs on low phosphorus rations to drink approximately twice as much water as those on sufficient rations; moreover urine excretion was nearly twice as great in proportion to water consumed for the former group as for the latter. The higher levels of phosphorus supplied to lots 2 and 3 proved adequate for normal growth and development, and no significant differences were noted in their effects.

Experiments 2 and 3, conducted primarily to establish the minimum phosphorus requirements within closer limits, confirm the results of the first experiment and indicate that the minimum phosphorus intake which permits normal growth and development lies between 0.27 and 0.3 percent of the ration. This is equivalent to a daily intake of about 6.5 g and 4 g of phosphorus per 100 lb. of live weight for 50-lb. pigs and 200-lb. pigs, respectively.

**Comparison of management methods for chicks, layers, and breeding hens.** C. W. UPP (*Louisiana Sta. Bul.* 275 (1936), pp. 14).—In two series of experiments early-hatched chicks grew faster and at a more uniform rate and showed a lower mortality than late-hatched chicks, clearly indicating the advantage of early hatching. Brooding results over a 4-yr. period showed that brooding on wire floors or in battery brooders is much more desirable than brooding on litter from the start or placing birds on litter at 4 weeks of age, particularly from the standpoint of coccidiosis control. Pullets placed in the laying house at 12 weeks of age were generally small at the beginning of the laying year and suffered relatively high mortality, with coccidiosis a contributing factor to this mortality.

Mortality of pullets in laying cages was generally similar to that of comparable lots with outdoor range and was consistently lower than that of pullets confined to laying houses, particularly those that did not have access to a sun porch. Birds having access to green feed in outdoor runs produced from 1 to 3 doz. more eggs and consumed less feed per bird and per dozen eggs than the confined lots. Fertility and hatchability were appreciably higher in the range pullets than in those confined on wire floors or stud mated in laying batteries.

**The blood sugar of the fasting, gizzardectomized fowl (*Gallus domesticus*).** W. H. BURROWS, J. C. FRITZ, and H. W. TYRUS (*Jour. Biol. Chem.*, 110 (1935), No. 1, pp. 39-41, figs. 2).—In a study at the U. S. D. A. Beltsville Research Center comparing the blood sugar level of normal and gizzardectomized cockerels during a fasting period it is shown that the difference between the curves for the control and the gizzardectomized birds is no greater than between individuals in either group, leading to the conclusion that the gizzard plays very little, if any, part in the fluctuations of the blood sugar level of fasting chickens.

**Effect of minerals and fiber on avian intestinal pH.** V. G. HELLES and R. PENQUITE (*Poultry Sci.*, 15 (1936), No. 5, pp. 397-399).—Results of five series of

tests conducted at the Oklahoma Experiment Station are reported. Experimental subjects ranged from 6-week-old chicks to 1-year-old hens, and the rations were varied to cover a wide range of intake of basic salts, calcium-phosphorus ratios, and crude fiber content. Samples of the contents from eight different sections of the alimentary tract were taken for pH determinations. The intake of large amounts of basic salts caused a marked decrease in acidity in the fore part of the alimentary tract, particularly in the gizzard, but changes in the intestines were of small significance. Neither the range of calcium-phosphorus ratios employed nor the wide range in crude fiber intake produced any significant changes in pH values. Evidently the digestive tract of the fowl is well equipped to care for the normal changes in the food and water ingested.

The vitamin A requirements of the laying pullet, W. C. RUSSELL, C. S. PLATT, M. W. TAYLOR, and D. F. CHICHESTER (*New Jersey Stat. Circ. 369 (1936), pp. 8*).—In the experiments herein reported seven pens of healthy pullets reared on range were started on experiment late in August and continued under confinement for a 12-mo. period. All lots received essentially the same basal ration, but the proportions of yellow corn and white corn and the supplements of alfalfa meal, vitamin A concentrate, and fresh green feed were varied so that the U. S. P. units of vitamin A per pound of feed were 400, 700, 1,800, 2,200, 3,800, 4,100, and 30,000 for lots 1 to 7, respectively. Data are reported on the percentage mortality, live weight changes, egg production, hatchability of eggs, mortality of chicks during the first 2 weeks of life, and vitamin A storage in the livers of the hens.

Aside from the somewhat higher mortality in lot 1 and the higher chick mortality in lots 1 and 2, there was no marked difference in the results obtained from the different lots. Maximum egg production was obtained from lot 4 (2,200 units). Values for liver vitamin A fell in essentially the order of the increasing amounts of this factor fed. Since 2,200 units of vitamin A per pound of ration, which is probably well below that present in poultry rations commonly fed, gave as satisfactory results as the larger quantities supplied in this experiment, it appears that the addition of more vitamin A to the usual poultry ration is of no value in improving egg production and hatchability or in reducing mortality.

A study of the vitamin A requirement of the chick during early life, R. C. RINGROSE and L. C. NORRIS (*Poultry Sci.*, 15 (1936), No. 5, pp. 390-396, fig. 1).—This contribution from the [New York] Cornell Experiment Station describes a biological method for assaying feeds for vitamin A, using chicks as test animals, based on the experimental findings that the vitamin A requirement of the chick during the first 8 weeks of life is about 150 U. S. P. X units per 100 g of feed consumed. Employing this method of assay yellow corn was found to contain 7 units of vitamin A per gram, and a number of corn gluten meal samples were found to contain from 7 to 25 units per gram.

Studies relative to the estimation of vitamin D.—IV, Effect of seasonal variation upon vitamin D assay, L. L. LACHAT and H. A. HALVORSON (*Poultry Sci.*, 15 (1936), No. 5, pp. 362-368, figs. 2).—Continuing this series of investigations (E. S. R., 75, p. 827), day-old White Leghorn chicks were placed on the A. O. A. C. rickets-producing ration, certain groups being started around March 1 and others about August 1. Lots in each group included negative controls and those receiving various levels of U. S. Pharmacopeia "reference cod-liver oil" as well as commercial cod-liver and other fish oils.

From data obtained on growth rates and bone ash analysis it is concluded that the chick's response to vitamin D additions is variable, with definite seasonal trends. The chick's requirement per 100 g of A. O. A. C ration during

the 4-week feeding period was about 26.7 U. S. P. units of vitamin D for the spring months and about 23.8 units during the late summer and autumn months. It was further noted that negative controls have higher average ash in the autumn months than in the spring months, this difference being characterized by more rapid growth rate during the former season. The desirability of having a standard preparation containing vitamin D for poultry to obviate errors in interpreting results of assays of vitamin D carriers at different seasons of the year is pointed out.

Observations on the vitamin G requirement of the chicken, C. H. HUNT, P. R. RECORD, and R. M. BERTHEKE (*Ohio Sta. Bimo. Bul.* 183 (1936), pp. 127-130).—In this experiment six lots of White Leghorn chickens were fed the same basal ration, known to be deficient in vitamin G, throughout the growth and production period. Vitamin G was supplied to the various lots in the form of 5 percent of alfalfa leaf meal, 5 percent of alfalfa leaf meal plus 2.5 or 5 percent of dried skim milk, and 2.5, 5, or 7.5 percent of dried skim milk, respectively.

The rate of growth was highly correlated with the amount of vitamin G consumed, the amount supplied from various sources being apparently of equal efficiency in promoting growth. The lots receiving the combined supplement produced the greatest number of eggs per hen. Those lots receiving 5 percent and 7.5 percent of dried skim milk produced well for a few months but declined rapidly in the latter months of the trial and suffered a high percentage of mortality. In the lots receiving the combined supplement the hatchability varied directly with the units of vitamin G transferred from the feed to the egg, but this condition did not hold true for hens receiving only dried skim milk, this supplement giving relatively low hatchability at all levels. The results indicate that the alfalfa leaf meal or a combination of alfalfa leaf meal and dried skim milk contain a factor or factors not contained in the dried skim milk alone and necessary for sustained production and good hatchability in the eggs so produced.

Energy and gaseous metabolism of normal and deutectomized chicks between 10 hours and 100 hours of age, H. G. BAROTT, T. C. BYERLY, and E. M. PRINGLE (*Jour. Nutr.*, 11 (1936), No. 3, pp. 191-210, figs. 7).—In studies at the U. S. D. A. Beltsville Research Center the heat production and gaseous exchange were determined for both normal and deutectomized chicks of both sexes by direct calorimetry. Chicks from 10 to 100 hr. of age were studied at atmospheric temperatures ranging from 68° to 104° F. The critical temperature was established at 96°. An increase or decrease of 7° from this critical temperature resulted in a 15-percent increase in metabolism, while further lowering of the temperature caused a constant rate of increase in metabolism until at 70° it was approximately doubled and the chicks unable to compensate for temperatures below 70°. Both normal and deutectomized chicks had a respiratory quotient of about 0.71 and a thermal quotient of 3.16, indicating a mixed fat and protein metabolism free of carbohydrates. The gram hour rate of metabolism for normal chicks was constant at any given temperature, but in deutectomized chicks it decreased continuously and in direct proportion to the time elapsed after the operation.

What is the effect of pure vegetable protein on the laying activity of hens? [trans. title], R. FANGAUF and O. BRÜNINGHAUS (*Arch. Geflügelk.*, 10 (1936), No. 6, pp. 173-187; *Eng. abs.*, p. 186).—In experiments comparing rations containing meat meal as a source of protein with rations containing only vegetable protein (soybean oil cake) for laying hens, it is indicated that under conditions of free range vegetable protein could replace animal protein during the summer months without unfavorably affecting egg production, but that in winter months some source of animal protein is necessary to maintain optimum

production. No difference was noted between the two types of rations as regards body weight or egg hatchability. The addition of mineral supplements to the vegetable protein ration produced no beneficial effects.

**The trend of egg production and mortality at the Vineland contest, C. S. PLATT** (*Poultry Sci.*, 15 (1936), No. 3, pp. 249-251).—The New Jersey Experiment Stations have analyzed the data obtained from the Vineland egg-laying contest, including all Single Comb White Leghorn hens entered over 14 yr. It is shown that the percentage of mortality steadily increased from 1918 to 1927, when it had more than tripled, and has remained at this high level. There was no increase in rate of egg production until 1927, but from 1928 to 1933 it increased slightly. In each year of the contest the birds that died produced at a lower rate than the birds surviving, indicating that they constantly represented a distinct type of birds. Apparently in recent years a higher percentage of birds entered in the contest were of the type which would die early in life regardless of level of production.

**Livability and production of pullet layers may be predetermined, D. C. KENNARD and V. D. CHAMBERLIN** (*Ohio Sta. Bimo. Bul.* 183 (1936), pp. 136-140).—This article is a further discussion of the problem previously noted (E. S. R., 75, p. 829). The difficulty of producing healthy layer pullets in close proximity to breeding and laying flocks is pointed out, and data are presented to show the superiority of pullets reared on comparatively disease-free farms over those reared in proximity to a breeding flock known to carry various poultry diseases. It is suggested that the production of disease- and parasite-free, livable, ready-to-lay pullets may be considered a desirable new phase of specialization in poultry raising.

**Influence of ovulation rate on the tendency of the fowl to produce eggs in clutches, H. M. SCOTT and D. C. WARREN** (*Poultry Sci.*, 15 (1936), No. 5, pp. 381-389).—In a study at the Kansas Experiment Station the authors have made observations on successive eggs laid by a group of 35 hens over a 28-day period. By palpation through the intestinal wall the forming egg can be detected in the isthmus of the oviduct about 4 hr. after ovulation. Tracing the eggs through the greater part of their formative period, it appears that either the first or second egg of the clutch required slightly more than 23 hr. to complete formation from the time it was first palpated in the oviduct. As further evidence that the first egg of the clutch required no longer time for formation than succeeding eggs, somite counts made on first and second eggs of the clutch after 38 hours' incubation were practically identical (8.64 and 8.79, respectively). When a clutch was terminated the first egg of the succeeding clutch could not be detected for more than 20 hr. after the previous egg was laid, thus indicating a delay in ovulation of more than 15 hr.

It is concluded that hens seldom ovulate in the afternoon, the "held" egg does not normally exist, the day of nonlaying is a result of delayed ovulation, and a new clutch is initiated when the hen lays the morning following the day of nonproduction.

**Effect of supplementary iodine on egg size and quality, E. A. JOHNSON** (*Poultry Sci.*, 15 (1936), No. 5, pp. 355-361).—In a trial conducted at the Minnesota Experiment Station three lots of White Leghorn pullets received a dietary supplement of potassium iodide at rates of 0.5, 2, and 4 mg per hen daily, respectively, and in a later trial two similar lots received 4 mg per hen daily and at a rate of 3 oz. per ton of mash ration, respectively. In each case eggs from the experimental pens were compared with those from control pens on the same basal ration without iodine supplements. In no case was there any significant difference in egg size, percentage of thick albumin, yolk index, yolk weight, yolk color, or shell thickness following the addition of iodine to the

diet. Evidently the hen's requirement for iodine was amply supplied in the ordinary ration.

**Sulfur in eggs,** H. W. MARLOW and H. H. KING (*Poultry Sci.*, 15 (1936), No. 5, pp. 377-380).—The Kansas Experiment Station has studied the distribution of sulfur in the yolk, thick white, and watery white of eggs and has found them to contain 1.08, 1.68, and 1.57 percent of total sulfur, respectively. In each instance sulfur was found to be organically bound and in the reduced form, the presence of cysteine being doubtful. Usually all the sulfur in either egg white or egg yolk is accounted for by the cystine and methionine sulfur.

**The marketing of quick frozen poultry:** The "Z" pack for ducks in the U. S. A., M. T. ZABOTSCHENZEFF (*Cold Storage*, 39 (1936), No. 461, pp. 190, 191, fig. 1).—This article briefly describes a method for quick freezing of poultry known as the Z process. In this process the dressed poultry is loaded on wooden trays and inserted into the freezing chamber, where a fine mist of brine at  $-5^{\circ}$  F. passes over the trays, resulting in a very rapid heat transfer with no resultant shrinkage of the product since a relative humidity of nearly 100 percent is maintained. After freezing each carcass is rinsed in clear water and dipped in ice water which forms a glaze of ice that protects against freezer burn during subsequent storage. The results of brief analytical tests show that the bacterial content of the meat of carcasses frozen by the Z process and the oleic acid value of the fat was much lower than in the case of freezing by the slower commercial method.

**Feed consumption and cost of feeding of Bronze turkey breeding stock,** S. J. MARSDEN (*Poultry Sci.*, 15 (1936), No. 5, pp. 400-404).—Studies at the U. S. D. A. Beltsville Research Center show that young Bronze breeding hens consumed an average of 117.12 lb. of feed each per year. The weekly feed consumption for an 8-week winter period, a 16-week spring period, a 24-week summer period (feed limited), and a 4-week autumn fattening period was 3.23 lb., 2.73, 1.4, and 3.5 lb., respectively. The males consumed approximately twice as much feed as the hens. Based on existing feed prices the annual feed cost for males and females was \$3.97 and \$1.94, respectively. Feed consumption by hens declined somewhat during the third, fourth, and fifth years of production.

## DAIRY FARMING—DAIRYING

[Abstracts of papers presented at the 30th annual meeting of the American Dairy Science Association] (*Jour. Dairy Sci.*, 19 (1936), No. 7, pp. 432-435, 436-448, 450, 452-510, 520-525, figs. 2).—Following are listed the titles and authors of papers pertaining either to dairy production or dairy manufacturing, presented at the annual meeting of the association (E. S. R., 74, p. 88) held at State College, Pa., June 1936: Studies on Aseptically Drawn Milk From Bang's Disease Positive and Bang's Disease Negative Cows, by H. B. Morrison and F. E. Hull (pp. 432, 433); Two Types of Blindness in Cattle and Their Possible Relation to Vitamin Deficiency, by A. H. Kuhlman, W. D. Gallup, and E. Weaver (pp. 433, 434); Production of White Spotted Kidneys in Calves, by L. A. Moore and E. T. Hallman (pp. 434, 435); Vitamin A Replaces Whole Milk in the Calf Ration, by H. T. Converse and E. B. Meigs (pp. 435, 436); Supplementing a Normal Ration for Dairy Calves With Cod Liver Oil, by P. M. Reaves and C. Y. Cannon (p. 436); The Physiological Effect of a Hegari Fodder and Cottonseed Meal Ration on Dairy Cows (Preliminary Report), by O. C. Cunningham, L. H. Addington, and E. M. Lantz (pp. 437, 438); The Vitamin A Requirements of Dairy Cows for Reproduction and Lactation Under Practical Conditions, by E. B. Meigs and H. T. Converse (p. 438); Reproduc-

tion of Dairy Cows on a Ration of Prairie Hay and Cottonseed Meal, by A. H. Kuhlman, E. Weaver, and A. Nalbandov (pp. 438, 439); The Effect of Sprouted Oats on Reproduction of Dairy Cattle, by H. P. Davis and I. L. Hathaway (pp. 439, 440); Magnesium Carbonate and Magnesium Oxide Supplements to a Whole Milk Ration for Dairy Calves, by C. F. Huffman and C. W. Duncan (pp. 440, 441); Gross and Microscopic Pathology Associated With Low Blood Magnesium in Dairy Calves, by L. A. Moore, L. B. Sholl, and E. T. Hallman (pp. 441, 442); Cod Liver Oil and Muscle Dystrophy in Calves, by G. Davis and L. A. Maynard (p. 442); Effect of Phosphorus Intake on the Calcium and Inorganic Phosphorus Content of Whole Blood of Dairy Heifers During the Periods of Gestation and First Lactation, by A. H. Van Landingham, H. O. Henderson, and G. A. Bowling (p. 443); Relative Utilization by Dairy Cows of Calcium and Phosphorus in Dicalcium (Dicalcium Phosphate) and Bonemeal (Tricalcium Phosphate), by J. A. Newlander, H. B. Ellenberger, and C. H. Jones (pp. 443, 444); Body Analyses of Dairy Cows After Long Time Calcium and Phosphorus Balance Trials, by H. B. Ellenberger, J. A. Newlander, and C. H. Jones (pp. 444, 445); The Influence of Roughage on the Vitamin D Potency of Milk, by G. C. Wallis and T. M. Olson (pp. 445-447); A Further Study of the Factor in Soybeans Affecting the Vitamin A Value of Butter, by J. W. Wilbur, S. M. Hauge, and J. H. Hilton (p. 447); The Rate of Change in the Vitamin A Content of Milk, by W. C. Loy, J. H. Hilton, J. W. Wilbur, and S. M. Hauge (pp. 447, 448); Site of Synthesis of Fat in the Mammary Gland, by P. Kelly and W. E. Petersen (p. 448); Comparisons of Arterial and Mammary Venous Bloods as Related to Milk Secretion, by W. R. Graham, Jr. (p. 450); The Vitamin A Content of A. I. V., Molasses, and Normal Silage and the Effect of Feeding These Silages Upon the Vitamin A Content of Milk, by I. L. Hathaway, H. P. Davis, and J. C. Brauer (p. 452); Studies on A. I. V. Silage.—I, Preparation and Feeding, by C. F. Monroe and C. C. Hayden (p. 453); Studies on A. I. V. Silage.—II, Nutrient Preservation and Physiological Effects on the Cow, by A. E. Perkins and C. F. Monroe (pp. 453, 454); Studies on A. I. V. Silage.—III, Carotene Preservation and Biological Properties of the Milk, by W. E. Krauss and R. G. Washburn (pp. 454-456); Photographic Techniques as Applied to the Dairy Industry, by R. F. Morgan (pp. 456, 457); Alignment Charts for Estimating Profit per Cow and per Unit Milk, by S. Brody and A. C. Ragsdale (p. 457); A Lesson in Feeds, by R. B. Becker (pp. 458, 459); Production of Dairy Cows When Fed Only Silage and Cracked Soybeans, by N. K. Williams, C. Y. Cannon, and D. L. Espe (p. 459); Methods of Making Grass Silage, by T. E. Woodward (p. 460); Sweet Potatoes versus Silage for Milk Production, by R. H. Lush (pp. 460, 461); Soy Bean Hay as the Sole Roughage for Dairy Cows, by L. F. Herrman and G. A. Bowling (pp. 461, 462); Limited Grain Feeding of Dairy Cattle, by C. E. Wylie and L. R. Neel (p. 462); The Value of Grinding Grains for Lactating Dairy Cattle, by A. L. Darnell and O. C. Copeland (pp. 462, 463); The Feed Value of Oat Mill Feed as a Hay Substitute for Dairy Cows, by A. W. Lathrop and G. Bohstedt (pp. 463, 464); Milk and Butterfat Yields of Holstein Cows on Rations Restricted to Roughage, by J. R. Dawson and R. R. Graves (pp. 464, 465); Some Results of Eight Years of Investigation Concerning the Role of Roughage in the Diet of Ruminants, by S. W. Mead and H. Goss (pp. 465, 466); Spectrophotometric Data Bearing on the Character of the Pigments Obtained in Routine Determinations of Carotene in Hays, Silages, and Freshly Cut Plant Materials, by E. A. Kane, H. G. Wiseman, A. H. Hartman, and C. A. Cary (p. 466); Rate of Decomposition of Carotene in Hays During Storage at Different Seasons of the Year, by H. G. Wiseman, E. A. Kane, and C. A. Cary (pp. 466, 467); Effect of Moisture Content and Density of Stored Roughage

on Temperatures Attained During Storage and the Quality of the Product, by J. B. Shepherd, T. E. Woodward, and R. R. Graves (pp. 467, 468); The Effect of Certain Factors Upon the Color and Pigments of Alfalfa Hay in Storage, by T. E. Woodward (pp. 468, 469); Results Obtained When the Several Minnesota Reagents Were Employed for Testing Buttermilk, by D. F. Breazeale and E. W. Bird (pp. 470, 471); The Effect of Preservatives on the Results Obtained With Ice Cream Mixes by Several Testing Methods, by P. H. Hostetler, C. A. Iverson, and E. W. **Report of the Chief of the Bureau of Dairy Industry, 1936, O. E. REED (U. S. Dept. Agr., *Bur. Dairy Indus. Rpt.*, 1936, pp. 28).**—Investigations with dairy cattle at the Beltsville, Md., and field experiment stations have yielded results on the carotene requirements of dairy cattle, the tolerance of calves to massive doses of cod-liver oil, factors affecting green color and carotene in alfalfa, roughage production and preservation, milk production on sole roughage rations, the development and use of permanent and annual pastures, breeding for high milk and butterfat production, several phases of the physiology of reproduction, the relation of the conformation and anatomy of the dairy cow to her producing ability, milk yield from separate quarters of the udder, and the relationship of udder development in calves under 6 mo. of age to their milk-producing ability during first lactation.

In studies with dairy products, results were obtained on the sporicidal action of ultraviolet rays, the sequence of change in the udder and in the chemical and physical properties of milk at the onset of mastitis, oxidation in dairy products, relation of acidity of cream to keeping quality of butter, factors affecting the stability of ice cream, cream-plug formation in bottled cream, curd tension of milk, and activity of chlorine solutions.

In the field of new methods and products, progress was reported in the production of synthetic fibers resembling wool from casein, the utilization of whey in producing lactic acid, the use of whey powder and whey cream in the prepara-

tion of various food products, the use of special paper bags for storing milk powders, partial dehydration and low temperature storage as a method of preserving milk over long periods, and methods for the successful manufacture of Bel Paese, Swiss, and Roquefort type cheeses and for canning natural Cheddar cheese.

[Investigations with dairy cattle and dairy products in Texas] (*Texas Sta. Rpt. 1935, pp. 120, 121, 122*).—Dairy cattle investigations reported include the feeding value of ground v. whole grains, by A. L. Darnell and O. C. Copeland; cottonseed meal and hulls as a ration for lactating dairy cows and the minerals necessary in commercial dairy feeds, both by Copeland; the vitamin A requirements for milk production and maintenance of dairy cows, by G. S. Fraps and Copeland; and permanent pastures in east central Texas, by Copeland, B. L. Warwick, and E. B. Reynolds.

**Cottonseed meal ration and silage versus herd ration, hay, and silage.** R. H. LUSH (*Louisiana Sta. Bul. 278 (1936), pp. 7*).—In the first of the experiments reported two simple grain feeds containing 75 parts of ground yellow corn plus 25 parts of cottonseed meal and 75 parts of ground yellow corn plus 25 parts of soybean oil meal, respectively, each supplemented with 2 percent of oystershell flour and 1 percent of salt were fed as the concentrate ration to groups of Holstein heifers throughout their growing period and during their first and second lactations. Roughage in each case was supplied as corn-soybean silage in winter and by pasture throughout the grazing season. No significant differences were noted in the results obtained from these two rations, each supporting growth gains of approximately 1 lb. per day to time of first freshening and each maintaining excellent milk production through the two lactation periods. When compared with a group of young cows on a more complex grain mixture of ground corn, oats, wheat bran, and cottonseed meal and salt with mixed grass and legume hay and corn-soybean silage as a roughage, and making allowance for apparent hereditary differences in the productive ability of the respective groups, the cows on the simple ration averaged 20.3 percent more fat-corrected milk than the latter group.

In a series of comparative trials by the reversal method, the corn-cottonseed meal-silage ration proved slightly superior to a mixed grain-dehydrated soybean hay-silage ration and only slightly inferior to mixed grain-dehydrated alfalfa hay-silage rations.

It is concluded that under the conditions outlined legume hay and a bulky grain ration are not necessary for economical production when silage or pasture, corn, cottonseed meal, and an adequate supply of minerals are fed.

**Growth and development of dairy calves on a milk diet.** H. A. HERMAN (*Missouri Sta. Res. Bul. 245 (1936), pp. 102, figs. 37*).—In this experiment three Holstein helper calves were reared on an unsupplemented whole milk diet and five similar calves on whole milk supplemented with iron, copper, manganese, and cod-liver oil.

All calves made supernormal growth during the early growth stage, and at 6 to 10 mo. of age they were about 20 percent above normal in body weight. During this period, in which food consumption was normal, the computed gross energetic efficiency was above normal. The calves receiving unsupplemented milk showed evidence of anemia after 6 mo. of age, closely followed by loss of appetite, difficult breeding, and physical weakness. These calves died at 323, 391, and 528 days of age, respectively. The calves receiving supplemented milk did not show evidence of anemia at any time, but at about 10 mo. of age began to show loss of appetite, followed by loss in weight, dyspnea, and physical weakness, and died at 333, 340, 373, 388, and 404 days

of age, respectively, in general surviving only about 1 mo. longer than calves on the sole milk diet.

All calves maintained normal blood values for calcium, phosphorus, and magnesium, and none developed tetany. Bone development was adjudged normal in all cases, although the group receiving cod-liver oil had slightly denser bones. The energy metabolism of both groups tended to be above normal, particularly after 6 to 8 mo. of age, when the calves were dyspneic, nervous, and irritable. The most prevalent post-mortem findings were hemorrhages of the kidney, lung, thymus, and heart, enlargement of the thymus, degeneration of the heart muscles, underdeveloped digestive organs, except the abomasum, and catarrhal condition and ulcerous areas in the pyloric end of the abomasum and the duodenum. No abnormalities were noted in the histological examination of various tissues. Death of the calves on the sole milk diet was attributed to anemia and of those on supplemented milk to a dietary deficiency, although the exact nature of this deficiency remains obscure.

**Amounts of feed and labor used in raising dairy heifers, H. O. HENDERSON, G. A. BOWLING, and L. F. HERRMANN (*West Virginia Sta. Bul.* 277 (1936), pp. 27, *Figs. 10*).—**This bulletin presents a summary of material obtained from two sources, (1) the feed consumed and labor required to grow Jersey and Holstein heifers to 2 yr. of age in the station herd, and (2) the estimated feed consumption and labor requirements for growing dairy heifers to 2 yr. of age based on a survey of 122 farms in different parts of the State. Extensive data on total feed and total digestible nutrients consumed, growth rates, a comparison of spring- and fall-born heifers, and the labor required at different seasons and for different sized herds are presented in tabular and graphic form.

Based on whole milk at \$2 and skim milk at 50 ct. per hundredweight, grain at \$26 and hay at \$15 per ton, pasture at \$1 per head per month, and labor at 15 ct. per hour, the feed and labor costs for raising station Holstein heifers, Jersey heifers, and West Virginia farm heifers to 2 yr. of age were found to be \$103.17, \$94.61, and \$73.21, respectively.

**A convenient method for obtaining bovine arterial blood, W. R. GRAHAM, JR., H. D. KAY, and R. A. MCINTOSH (*Roy. Soc. [London] Proc., Ser. B*, 120 (1936), No. 818, pp. 319–329, *fig. 1*).—**This contribution describes a technic for obtaining samples of arterial blood from the internal iliac artery per rectum simultaneously with the collection of venous blood from the mammary vein. The suitability of this technic in obtaining blood samples for experimental study of the possible precursors in blood of the milk constituents is discussed.

**The precursors in cows' blood of milk fat and other milk constituents, W. R. GRAHAM, JR., T. S. G. JONES, and H. D. KAY (*Roy. Soc. [London] Proc., Ser. B*, 120 (1936), No. 818, pp. 330–346, *Figs. 3*).—**Employing the technic described above, simultaneous samples of arterial and venous blood were drawn from lactating cows. By determining the concentration of cholesterol, phospholipin, phosphoric esters, fatty acids, inorganic phosphorus, and blood sugar in the two samples and determining the reduction in concentration of these constituents after the passage of blood through the mammary gland, certain tentative conclusions were reached relative to the precursors in the blood of various milk constituents.

The fat of cows' milk is derived primarily from the nonphospholipin fatty acids of the blood, probably those of neutral fat, although the cholesterol esters may also be involved. Phosphorus compounds of milk are derived largely from the inorganic phosphorus of the blood plasma. The phospholipin content of the blood is not noticeably affected by its passage through the mammary gland, indicating that it plays little part as a precursor of either milk fat or

milk phosphorus. Marked quantities of sugar disappear from the blood during its circulation through the mammary gland, the percentage varying with the sugar concentration of the blood and also with the volume of milk secreted.

It is shown that the volume of blood required to produce a volume of milk is of the same order whether based on the fatty acid change, inorganic phosphorus change, or sugar change of blood during its passage through the udder. There is definite evidence of a very rapid circulation of blood through the udder of heavy-producing cows, estimated to be of the order of 1.25 gal. of blood per minute for a cow yielding 4 gal. of milk per day.

The effect of thyroxine on milk secretion and on the phosphatase of the blood and milk of the lactating cow, S. J. FOLLEY and P. WHITE (*Roy. Soc. [London] Proc., Ser. B*, 120 (1936), No. 818, pp. 346-365, figs. 10).—The observation that the blood serum phosphatase of individual dairy cows varied quite widely led to this investigation. Four cows weighing from 562 to 600 kg each and from 13 to 24.5 weeks advanced in lactation were given daily subcutaneous injections of 10 mg of thyroxin over a 15-day period, the experimental period being preceded and followed by an 8-day normal control period.

The thyroxin treatment caused some increase in serum phosphatase, although not enough to justify the conclusion that differences in the level of plasma phosphatase among individual cows is due to differences in thyroid activity. In each instance thyroxin caused a pronounced increase in milk yield and at the same time an increase in the percentage of fat and solids-not-fat in the milk, but resulted in a sharp decline in the production of phosphatase in milk, this reduction being most pronounced in milk having the highest initial concentration. No evidence obtained in the study indicates that milk phosphatase is derived directly from that in the blood serum. Immediately following the injection period, milk yield, milk phosphatase, serum phosphatase, and serum inorganic phosphorus declined to subnormal levels, probably due to the fact that normal thyroxin activity was depressed during the period of thyroxin injection and required some time to return to normal.

The reduction of methylene blue at 15.5° C (60° F) as a test of keeping quality of milk, A. L. PROVAN, F. J. DUDLEY, and S. B. THOMAS (*Welsh Jour. Agr.*, 12 (1936), pp. 150-155).—When the methylene blue reduction test was carried out in stoppered tubes, incubated at 15.5° and shaken twice daily, a rather close agreement was noted between the reduction time and the time required to develop taints to off flavors in the milk. When evaluated to the nearest half day the reduction time is somewhat less than that required for development of off flavors, up to the seventh half-day period, but beyond this the reduction time is greater than the directly observed keeping quality. This condition is attributed to the presence of bacteria other than lactic acid types, which develop off flavors without acid production, and the accompanying decrease in the reduction oxidation potential in the milk.

Bottled concentrated whole milk, P. H. TRACY (*Amer. Creamery and Poultry Prod. Rev.*, 82 (1936), No. 8, pp. 258, 259).—This article from the Illinois Experiment Station briefly discusses bottled concentrated whole milk from the standpoint of its keeping quality and flavor and consumer reactions to this product. Certain factors relating to the possible future expansion of marketing milk in this form are pointed out.

The evaporation and spray systems of cooling cream, W. H. MARTIN, W. J. CAULFIELD, and A. C. FAY (*Kansas Sta. Circ.* 180 (1936), pp. 16, fig. 1).—Data are presented on the relative effectiveness of these two simple methods of cooling cream which are commonly employed on the farm and in cream-receiving stations.

The efficiency of the evaporation or wet sack method is not materially affected by the type of cloth used for wicking. The degree of air circulation and the relative humidity and temperature of the atmosphere as well as the initial temperature of the cream affect the rate of cooling, while room temperature and relative humidity largely determine the ultimate attainable temperature. Average room temperatures of 85°, 86°, and 98° F. at relative humidities of 49, 69, and 33 percent result in can temperatures (cooled by evaporation) of 70°, 78°, and 75°, respectively. The efficiency of the spray method of cooling is primarily dependent upon the temperature of the water and the volume of water delivered per unit of time. The use of sack coverings did not increase the efficiency of this method, indicating that evaporation plays a relatively small part in spray cooling. Sour cream, due to its greater viscosity, cools more slowly and less uniformly than sweet cream unless agitated frequently during the cooling process.

**Rate of temperature change in butter packed in boxes of different types,** F. H. McDOWALL (*New Zeal. Jour. Sci. and Technol.*, 17 (1936), No. 5, pp. 666-673, figs. 5).—This study deals with the relative insulating effect of standard butter boxes ( $\frac{5}{8}$ -in. ends,  $\frac{1}{2}$ -in. sides, top, and bottom), substandard boxes ( $\frac{5}{8}$  by  $\frac{3}{4}$  in.), and wire-bound boxes ( $\frac{1}{4}$ -in. material throughout) as determined by the rate of rise in butter temperature when lots of butter in each type of container were removed from frozen storage and exposed to room temperature of about 69° F.

A pronounced lag was noted in the temperature rise on the butter surface, due to the greater insulating effect of the thicker box material. It is concluded that under best conditions of transportation this difference would be of doubtful value, but that under less favorable transport conditions the thicker boxes would prove a valuable safeguard to the quality of the packed butter.

**The application of the catalase test to butter,** G. CUESS-CALLAGHAN (*Roy. Dublin Soc. Sci. Proc., n. ser.*, 21 (1936), No. 28, pp. 253-255).—The author has made a statistical analysis of the data previously published by other investigators regarding the relation between the catalase test on butter samples and either the quality score or the keeping quality of the butter.

A correlation of  $-0.4$  between the catalase value and the quality score of butter is shown, while the correlation between catalase test and keeping quality was of the same order. These findings are of particular interest in view of the fact that other workers have shown correlations ranging from 0.191 to  $-0.96$ . The apparent reasons for such wide variations are pointed out.

**Bacteriological studies on musty flavour in butter,** H. H. RANDELL (*Jour. Austral. Inst. Agr. Sci.*, 2 (1936), No. 1, pp. 23-26).—A study of the butter defect known as musty flavor indicates that a specific, previously undescribed species of the genus *Achromobacter* is the causative bacterium. The morphology and cultural characteristics of the organism are described. Improperly sterilized wooden utensils, water hose, and the water supply are listed as probable sources of contamination for this organism.

## VETERINARY MEDICINE

[Work in animal pathology by the Colorado Station] (*Colorado Sta. Rpt.* 1936, pp. 19, 39-41).—The following work in animal pathology in 1935-36 is briefly reported upon (E. S. R., 75, p. 252): Mineral deficiencies and nutritional diseases, particular reference being made to intoxication by timber milkvetch (*Astragalus campestris*), an account of which has been noted (E. S. R., 75, p.

539); losses of lambs and of sheep; Bang's disease; equine encephalomyelitis; and oat-hay poisoning.

[**Work in animal pathology and parasitology by the Texas Station**] (*Texas Sta. Rpt. 1935*, pp. 13-18, 22, 120, 234-240).—The work of the year with livestock affections (E. S. R., 75, p. 102) briefly reported includes loin disease of cattle, infectious bovine abortion, stomach worms (*trichostrongyles*) in sheep and goats, anaplasmosis, miscellaneous poisonous plants, hard yellow livers in sheep and cattle, sheep losses in the feed lot, chronic nephritis in cattle and sheep, and a further outbreak of the new disease in cattle reported upon the preceding year, all by H. Schmidt; stomatitis and laminitis in sheep, by F. P. Mathews; locoweed poisoning, by G. S. Fraps and E. C. Carlyle; Bang's disease, by Schmidt and O. C. Copeland; and at the Sonora Substation the toxicity of bitterweed (*Actinea odorata*), by I. B. Boughton and W. T. Hardy, hard yellow livers of sheep and cattle, by Boughton, Hardy, and V. L. Cory, contagious ecthyma (sore mouth) of sheep and goats and stomach worms (*Haemonchus contortus*) of sheep and goats, both by Boughton and Hardy, and feeding trials of poisonous plants.

**Selective habitat of the poisonous *Astragalus hylophilus* (Rydg.) A. Nels., O. A. BEATH** (*Ecology*, 17 (1936), No. 4, pp. 692-694).—The finding in Wyoming that *A. hylophilus* (*A. campestris* Gray), known as timber milkvetch, is restricted in growth to soils derived from the Hanna and Bishop conglomerates and may be taken as a plant indicator of these geological formations in situ, is reported. The increased activation of the toxic principle or principles in *Astragalus* spp. caused by the toxic element selenium, first reported by Beath and his associates in 1934 (E. S. R., 72, p. 251), does not occur in *A. hylophilus*. The pathology of affected animals points definitely to a toxic mineral activation. Tin, molybdenum, and arsenic in organic combination have been isolated from plant extracts. In addition to its selective soil preference it has another unique habitat in that its occurrence in areas within the Hanna and Bishop conglomerates is quite generally confined to aspen growths, aspen-pine associations, and pines. Under suitable soil and moisture conditions the continuity of growth is so persistent that the ground frequently is more or less completely covered by it.

It is a poisonous plant particularly troublesome to livestock men in south-central and southwestern Wyoming (E. S. R., 67, p. 738).

**Tissue culture studies on bacterial hypersensitivity, I-III** (*Jour. Expt. Med.*, 64 (1936), Nos. 3, pp. 339-368, pls. 2, figs. 7; 6, pp. 943-951, pls. 2).—This contribution is presented in three parts.

**I. Tuberculin sensitive tissues**, J. K. Moen and H. F. Swift (pp. 339-353).—In the studies here reported a high degree of cellular sensitivity to tuberculin toxicity was demonstrated when explants from tuberculous animals were grown in media containing that substance. "Similar degrees of sensitivity were noted in cells derived from animals infected with either virulent or relatively lowly virulent strains of tubercle bacilli. The specificity of the tuberculin cytotoxicity was proved by testing with other bacterial cytotoxic materials. Tuberculin sensitive cells grown in vitro in normal media showed, when tested with tuberculin, persistence of this cellular sensitivity through several transplantations, during which time many new generations of cells developed. There was a depression of the initial growth energy of explants from animals during the toxic phase of the disease. During the healing stage the initial growth energy returned to normal, although marked sensitivity to tuberculin persisted. The degree of cellular sensitivity to tuberculin in vitro did not parallel the acuity of the infectious process but represented a more or less

permanent acquired characteristic impressed on the cell as a result of the infection."

II. *Reactions of tissues from guinea pigs infected with group C hemolytic streptococci*, J. K. Moen (pp. 355-368).—It was found that "guinea pigs infected with naturally pathogenic hemolytic streptococci (group C—Lancefield) develop a low grade chronic type of disease characterized chiefly by purulent lymphadenitis. Cutaneous hyperreactivity to a crude streptococcal extract invariably occurred during the course of this infection. Production of antibodies (precipitins and agglutinins) was studied. The hemolytic streptococcal extract had a specific toxic effect, when tested in vitro, on cells from infected animals; this was shown by microscopic evidence of cellular injury and by quantitative inhibition of cellular migration and growth. The specificity of the reaction was proved by testing with other cytotoxic substances. There was no parallelism between skin hypersensitivity and humoral antibody titer. There was no correlation between the degree of skin reactivity to the bacterial extract and the degree of sensitivity of splenic cells to the toxic action of the same extract in vitro. Comparison of cellular sensitivity to tuberculin with cellular sensitivity to streptococcal extract in cultures of guinea pig tissues showed that the former was more intense and was more persistent on prolonged growth in vitro."

III. *The persistence in vitro of the inherent sensitivity to tuberculin of cells from tuberculous animals*, J. K. Moen (pp. 943-951).—"Mononuclear exudative cells obtained from tuberculous guinea pigs by the intrapleural injection of parowax exhibited characteristic sensitivity to the toxic action of tuberculin when tested in tissue culture. Experiments with these cells, practically free of body fluids, show conclusively that sensitivity to tuberculin is an inherent characteristic of mesenchymal cells from tuberculous animals. Fibroblastic growths which developed from mononuclear exudative cells derived from a tuberculous animal showed persistence of sensitivity to the toxic action of tuberculin on repeated transplantations over a prolonged period in vitro."

*Immunization against anaplasmosis and piroplasmosis*, T. TOPACIO (*Philippine Jour. Anim. Indus.*, 3 (1936), No. 3, pp. 169-179).—Following a brief introduction, a review of the literature, and descriptions of materials and methods, three experiments are reported, one consisting of immunization by single infection (*Anaplasma* group), one by double infection (*Piroplasma-Anaplasma*), and one by single infection (*Piroplasma*). The information gained from the first would indicate that the subcutaneous and intravenous inoculation of blood from *Anaplasma* carriers in doses of varying amounts gives satisfactory results in Batangas calves. The second experiment showed that the subcutaneous and intravenous inoculation of carrier blood containing both infections into susceptible Batangas calves even at a low dose of 5 cc was still too severe for purposes of immunization. The third experiment indicates that the ideal method of immunizing against piroplasmosis is by the use of blood obtained when the red cells showed the bigeminal forms of the parasites and injecting 2 to 3 cc of such blood.

It is concluded that the ideal method of protection consists in immunizing against the first disease and after complete recovery against the second according to the method employed in the third experiment.

*The size of the virus of Anjeszky's disease ("pseudo-rabies", "infectious bulbar paralysis", "mad-itch") by ultrafiltration analysis*, W. J. ELFORD and I. A. GALLOWAY (*Jour. Hyg. [London]*, 36 (1936), No. 4, pp. 536-539).—In the experiments reported, broth suspensions of brain or lung tissue from rabbits in advanced stages of Anjeszky's disease were analyzed by fractional ultrafiltration through graded collodion membranes with a view to estimating

the size of the virus particles. The virus was found to have a particle size of 100-180 m $\mu$ . Two strains were employed in these experiments, one that of Aujesky (E. S. R., 14, p. 707) and the other Shope's mad-itch strain (E. S. R., 65, p. 872). The results with both strains were identical.

**Rabies among hematophagous bats (*Desmodus rotundus murinus*)** [trans. title], S. TORRES and E. DE QUEIROZ LIMA (*Rev. Dept. Nac. Prod. Anim. [Brasil]*, 2 (1935), No. 4-6, pp. 385-405, figs. 10; Eng. abs., pp. 324, 395).—The authors find that naturally or when experimentally infected bats can resist the rabies infection, becoming carriers and eliminators of the virus with which they inoculate the animals they attack to suck the blood. Hematophagous bats, when infected, disseminate the virus among themselves and can transmit it to bats not hematophagous. The salivary glands are viruliferous, but the virulence does not always coincide with that of the brain and vice versa. The results observed indicate that the rabies virus, after having passed through the central nervous system, can remain and probably ends in the salivary glands.

**The utilization of sheep in the rabies vaccine protection tests**, J. E. SCHNEIDER (*Jour. Amer. Vet. Med. Assoc.*, 89 (1936), No. 6, pp. 671-676).—The use of the intralingual method of administering the infective dose of rabies virus has given consistent results in the protection test of rabies vaccine on rabbits. The results on sheep have shown that the method is suited for this type of protection test. "It has been shown that rabies vaccine A, containing 25 percent rabbit brain and cord tissue, protected rabbits in a single 5-cc dose or in 14 doses of 0.5 cc each at daily intervals. The tests also show that rabies vaccine B, containing 20 percent horse brain and cord tissue, protected rabbits equally as well as the rabbit vaccine A in the group injected with 14 doses of 0.5 cc each at daily intervals. The group of rabbits injected with a single 5-cc dose of vaccine A were 100 percent protected, whereas with vaccine B one rabbit out of six died. Rabies vaccine B, containing 20 percent horse brain and cord tissue, showed a high degree of protection in each of the three groups of sheep."

**Further studies on *Fascioloides magna* (Bassi 1875) Ward 1917 as a parasite of ruminants**, W. E. SWALES (*Canad. Jour. Res.*, 14 (1936), No. 8, Sect. D, pp. 83-95, pls. 3).—A report is made of comparative studies (E. S. R., 73, p. 100) of the tissue reactions in fascioloidiasis magna in *Bos taurus*, *Bison bison*, *B. taurus*  $\times$  *B. bison*, *Cervus canadensis*, *Odocoileus virginianus*, and *Ovis aries*. The data support the hypothesis that the Cervidae are normal hosts in the trematode's life cycle, that the large Bovidae do not act in this capacity, and that *O. aries* may act as a definitive host but is severely injured by even light infestations. The cellular bases of the defense reactions in the above ruminants are recorded.

**John's disease in Victoria**, H. E. ALBISTON and R. J. DE C. TALBOT (*Austral. Vet. Jour.*, 12 (1936), No. 4, pp. 125-138).—John's disease does not appear to be a serious problem in Australia at the present time, Victoria being the only State in which it has become established. In the 17 yr. since its recognition in that State, it has extended to only 13 properties. The history of its occurrence in each of these herds is reported upon.

**Morphological and chemical studies of the blood of cattle in health and during anaplasmosis**, C. W. REES and M. W. HALE (*Jour. Agr. Res. [U. S.]*, 59 (1936), No. 7, pp. 477-492, fig. 1).—In studies of anaplasmosis the only significant changes from normal that could be measured were those resulting directly or indirectly from the destruction of the blood cells of the host by the causative agent of the disease. The red blood cell count was greatly reduced, with a consequent reduction in the hemoglobin and the oxygen content and

oxygen carrying capacity of the blood. The carbon dioxide content of whole blood and of serum was only slightly reduced. The overloading of the blood stream with cellular debris produced a bilirubinemia that was detectable by the direct Van den Bergh reaction. The white cell count showed a leucocytosis involving a relative monocytosis; and a neutrophilia with a shift to the left (Shilling's formula), but, on the other hand, there was an eosinopenia. The total proteins, urea, sugar, phosphorus, and calcium of the blood were not measurably altered from the normal.

One thousand cows testing suspicious (1 : 50) to the Bang agglutination test and their subsequent test behavior, C. H. KITSELMAN (*Jour. Amer. Vet. Med. Assoc.*, 89 (1936), No. 6, pp. 678-680).—Work with Bang's disease by the Kansas Experiment Station extending over a period of 5 yr. is reported. "At the expiration of 5 mo., 60.1 percent of the cattle which had reacted in a dilution of 1 : 50 had become definitely negative to the test and 23.1 percent had become definitely positive in a dilution of 1 : 100 or higher, whereas 16.8 percent remained unchanged in the suspicious classification. Approximately 41.6 percent of the suspicious animals on the initial test were in the group of herds having 17.9 percent infection, 23.3 percent were in the group having 17 percent infection, 22 percent were in the group of herds having 12.3 percent infection, and 13.1 percent were in the group showing 10.1 percent initial infection. It seems, therefore, that practically all animals found to be reactors in a dilution of 1 : 50 on the initial test will definitely become either negative or positive within a period of 9 mo., and many within a period of 5 mo. These data may be of use in advising herd owners regarding the disposition of certain animals which react in the 1 : 50 dilution when the herd test history is available."

About the relation existing between the gaseous oedema and the diseases that cause the anemia, with special regard to piroplasmosis and anaplasmosis, A. BRAGA and A. MARTINS (*Rev. Dept. Nac. Prod. Anim. [Brazil]*, 2 (1935), No. 4-6, pp. 263-305, figs. 4; *Eng., Fr. abs.*, pp. 289-296).—The authors report that "three times cases of gaseous gangrene in bovines submitted to premunition against *Piroplasma bigeminum* and *Anaplasma marginale* were registered. There is some predisposition to the anaerobic infection in the cases of pneumopathia, cachectic diseases, and in the hemoparasitoses. In all the cases the *Olostridium oedematis-maligni* was isolated, identified by its morphological, cultural, biochemical, serological, and immunological properties.

"We must attribute the occurrence of the cases of gaseous gangrene in bovines during the period of immunization against the plasmoses: (1) First, to a predisponent cause—anemia and bad oxygenation of the tissues, by the deficiency of red globules, oxygen vehicles; (2) second, to the frequent inoculations by the parenteral vine; (3) finally, to the infection of intestinal origin, as the *O. oedematis-maligni* is an ubiquitous germ, easily absorbed with the food, and the water, becoming a saprophyte of the intestines, specially of the herbivorous intestines.

"Although they had been vaccinated against the symptomatic anthrax, there were suspicions that the *O. chauvoei* [sic] might have caused the cases of death [the etiological identification being urgent]. The test in guinea pigs, protected with the monospecific sera, and 24 hr. later inoculated with the material to be identified, is very practical. After the germ had been identified, 60 cc of anti-*O. oedematis-maligni* serum were individually inoculated in nearly 80 bovines, no more cases being registered. Before this the illness invaded largely, as in the preceding years.

"The tests of agglutination and of fixation of the alexin are two means that can help the identification of the anaerobe germs, but certain technical cares should be taken. In the premunition against the plasmoses it is better to

use attenuated infested blood, as we actually do, so that a slight reaction might prevent our intervention with injectable drugs. Caffeine and adrenaline, specially the latter, which is ischemiant, should be given per os, when their use should be advisable.

"The biochemic differentiation between the *C. chauvoei* and the *C. oedematis-maligni* lies in the fact that the former ferments saccharose and does not act on salicin, while the latter ferments both of them. Nevertheless, some authors mention strains of *C. oedematis-maligni* that do not ferment saccharose (type II) and others that ferment it (type I). Thus classifying, the germs we isolated would be of type I."

Experiments on the infectivity for healthy calves of bovine tubercle bacilli discharged in dung upon pasture.—I, From tubercular calves fed with emulsions of tubercle bacilli 1934-5; II, From tubercular cows passing tubercle bacilli in their dung 1935-6, E. C. G. MADDOCK (*Jour. Hyg. [London]*, 36 (1936), No. 4, pp. 594-601).—The experiments reported show clearly that the pasture land must have been heavily infected with tubercle bacilli which at the time of their deposition were virulent when introduced subcutaneously into guinea pigs. "For 42 days after deposition, the dung of the infecting cow was shown to contain living tubercle bacilli, but by the technic used their survival was shown to be of comparatively short duration compared with the survival times shown for artificially infected dung. It is possible that mere numbers may account for the difference. The area used for the experimental grazing was only two-elevenths of an acre, and the weight of infection must have been far heavier than would normally take place on a farm. In spite of this fact none of the experimental healthy calves was shown to be infected. It seems, therefore, that in pasture which has been previously naturally infected, so long as no contact with the infecting animals is possible healthy animals may be expected to escape infection from this source. It therefore appears that the danger of infection being picked up from pasture manured with farmyard manure is remote. The most likely mode of spread of the disease is by contact of animal with animal either in the open or in cowsheds."

The control of black disease by vaccination, A. L. ROSE (*Austral. Vet. Jour.*, 12 (1936), No. 5, pp. 185-189).—The use of the vaccine proposed by Turner in 1930 (*E. S. R.*, 63, p. 874) over three successive seasons indicates that this method of controlling enterotoxemia in cross-bred lambs bred for the fat market is of outstanding value.

Infectious necrotic hepatitis (black disease) control, with special reference to vaccination: With a note on vaccination against entero-toxaemia and black leg, R. N. WARDLE (*Austral. Vet. Jour.*, 12 (1936), No. 5, pp. 189-192).—Liver fluke control by snail eradication and carbon tetrachloride treatment of sheep, combined with the limiting of the spread of *Clostridium oedematiens* by the burning of carcasses, offers a means whereby infectious necrotic hepatitis can be controlled on many properties. Vaccinations have proved so effective as a means of control that losses can be greatly reduced in this way on properties where fluke eradication is impracticable.

The control of black disease, blackleg, and entero-toxaemia in Tasmania, W. G. BENNETT (*Austral. Vet. Jour.*, 12 (1936), No. 5, pp. 192-196).—A report on control work in Tasmania.

The control of entero-toxaemia of sheep, H. W. BENNETTS (*Austral. Vet. Jour.*, 12 (1936), No. 5, pp. 196-200).—Experimental data and field evidence are said to indicate that active immunization with *Clostridium oedematiens* anaculture provides a safe, efficient, and economical method of protection.

**Further studies on the pathogenic importance of *Ochabertia ovina*, G. KAUZAL (*Austral. Vet. Jour.*, 12 (1936), No. 3, pp. 107-110).**—In the course of the experimental work here reported, the author confirmed earlier findings that *C. ovina* may lead to serious intestinal derangement and interference with growth in lambs.

"In the case of daily infestations with small numbers of larvae over a long period severity of the symptoms was not proportional to the rate of infestation. Evidence was obtained that immature *C. ovina* ingest considerable quantities of blood. Effects which would probably have proved fatal were induced only on one case, where heavy infestation with *C. ovina* was superimposed on a preexisting infestation with *Trichostrongylus* spp. It was not possible to set up other than light and fleeting infestations with the adult parasite, and factors other than those controlled in this experiment appear necessary for the establishment of heavy infestations with the adult worm. The specific effects due to the adult parasite have, therefore, not been studied."

**Salmonella onderstepoort: A new type of Salmonella from a sheep, M. W. HENNING (*Jour. Hyg. [London]*, 36 (1936), No. 4, pp. 525-531).**—During the course of the investigation of *Salmonella* infection in animals in the Union of South Africa the author encountered two strains that had been isolated from sheep at Onderstepoort. The antigenic structure of one corresponded fully with that of *S. typhimurium*, while the other was found to represent a new type possessing serological characteristics not hitherto described, for which the name *S. onderstepoort* is proposed.

**Studies in tick-borne fever of sheep.—II, Experiments on transmission and distribution of the disease, J. MACLEOD (*Parasitology*, 28 (1936), No. 3, pp. 320-329).**—In continuation of the studies previously noted (E. S. R., 69, p. 590) it was found that female castor-bean ticks which feed on a sheep infected with tick-borne fever are not capable of transmitting the infective agent to their progeny. "Only the nymphs and females, therefore, can be infective to sheep. In the case of an infective female, the infection may have been acquired (1) in the immediately preceding stage, or (2) in the larval stage, the infective agent remaining in the tissues of the tick during the nymphal engorgement and subsequent molt. This appears to occur irrespective of whether the host on which the nymph feeds is a susceptible or an insusceptible animal.

"Ticks which have acquired infection are infective as soon after molting to the next stage as they are able to attach to hosts. Unfed ticks were not found to be infective after a period of about 14 mo. Infection is transmitted to the sheep in the course of the second day after attachment of infective nymphs. The disease may be transmitted to sheep by inoculation of emulsions of infective ticks, if these have been allowed to commence engorgement. The use of saline for such emulsions appears to be inadvisable."

**The effect of carbon tetrachloride on sheep, H. C. KENNAN (*Austral. Vet. Jour.*, 12 (1936), No. 4, pp. 150-153).**—In a study of the effect of the continuous administration of carbon tetrachloride to sheep in combating the liver fluke (*Fasciola hepatica*), experiments were conducted which have shown the administration of 1 ml or 5 ml at intervals of 2 weeks or 1 mo. for a period of 10 mo. to result in a satisfactory growth and without producing any recognizable ill effects. On post-mortem examination there was no evidence of any damage to the liver, and the flesh was not affected as regards toughness or palatability. Old fluke-free sheep drenched (1) fortnightly or (2) monthly with either 1 ml or 2 ml of carbon tetrachloride for 10 mo. suffered no ill effect, and on post-mortem examination no damage to liver could be detected. Pregnant ewes drenched monthly with 2 ml during the last 4 mo. of the gestation period, and

thereafter for another 4 mo., lambed and raised their lambs without showing any ill effects from the treatment.

**Medicinal treatment of trichostrongylosis:** Efficiency in lambs exposed to continuous infection, H. MCL. GORDON and I. CLUNIES ROSS (*Austral. Vet. Jour.*, 12 (1936), No. 3, pp. 111-113, fig. 1).—In the experiments conducted, "sheep exposed to daily infection with 4,000 *Trichostrongylus* spp. did not develop trichostrongylosis and made satisfactory weight gains when treated with an appropriate dose of a 2-percent solution of copper sulfate and commercial nicotine sulfate. Sheep similarly exposed to infection, but treated with copper sulfate followed by tetrachlorethylene, appeared also to receive a high degree of protection. All sheep not treated medicinally with either of the above combinations of drugs succumbed to trichostrongylosis in from 70 to 141 days. Increasing the resistance of animals to *O[lostridium] oviscapis* does not modify the disease under experimental conditions."

**A contribution to the study of brucellosis of swine** [trans. title], O. PRIMO, E. HARDMAN, and J. BIFONE (*Folha Vet.*, 1 (1936), No. 5, pp. 70-79; *Eng. abstr.*, p. 79).—In the course of abattoir inspection the authors have observed the presence of nodular and caseous lesions in the spleen of swine without involvement of the lymphatic system as is observed in tubercular infection. *Brucella* agglutinins were found in two cases, and cultures of the germ were obtained from the spleen lesions. Twelve strains of *B. suis* were isolated from 50 cases, the typing of the organism having been made by the dye method.

**Serial passage of hog cholera virus in the guinea pig, with a resulting loss of virulence for the hog** [trans. title], F. LECHUITON, C. MISTRAL, and J. DUBREUIL (*Compt. Rend. Acad. Sci. [Paris]*, 202 (1936), No. 1, pp. 96-98, fig. 1).—The hog cholera virus was passaged through guinea pigs by intratesticular inoculation. After a continued passage the virus became adapted to the guinea pig and lost most of its virulence for swine.

**Crystal-violet vaccine for the prevention of hog cholera.**—Progress report, C. N. McBRAYNE and C. G. COLE (*Jour. Amer. Vet. Med. Assoc.*, 89 (1936), No. 6, pp. 652-663).—In the work reported, 63 lots of vaccine were prepared with crystal violet dye by several methods and tested on a total of 271 pigs, the vaccine-treated pigs being exposed to hog cholera by virus injection. Of these, 266 proved to be adequately protected against hog cholera. The injection of virus caused a slight reaction in about 9 percent of the treated animals. This reaction, which occurred as a rule between the fourth and eighth days and lasted only 2 or 3 days, was followed by a quick return to normal. The reaction was usually so slight that it would have escaped notice in most cases but for the fact that each animal was carefully watched at feeding time. In one farm experiment in which 40 sows weighing from 50 to 90 lb. were given 10 cc each of vaccine, half of the herd having been exposed later by virus injection after the animals had attained a weight of from 200 to 250 lb., all were found to be adequately protected against hog cholera. From 2 to 3 weeks seem to be required for the immunity to become established. The duration of the immunity following vaccine treatment has not been established, but was found to be at least 6 mo.

**Resistance of the Berkjale breed of swine to hog cholera**, M. MANRESA and M. MONDOÑEPO (*Philippine Agr.*, 25 (1936), No. 3, pp. 214-220, figs. 2).—The origin of the Berkjale breed, a cross of the purebred Berkshire and the native Jalajala breeds of swine, is discussed. In the building up of this breed of swine selection for resistance against disease was not overlooked, and it is believed that much progress in the development of a strain of pigs of high resistance against hog cholera has been shown by the data presented.

**Practical methods of control and eradication of kidney-worm disease of swine, Z. DE JESUS** (*Philippine Jour. Anim. Indus.*, 3 (1936), No. 4, pp. 295-305, fig. 1).—Three practical methods of control and eradication of the kidney worm (*Stephanurus dentatus* Dies.) disease of swine are described and reported. Kidney worm-free pigs could be produced from infested sows by applying any one of the three methods described, thus eradicating the kidney worm infestation among the first generation of pigs.

"In order to avoid long exposure of the kidney worm-free pigs to the infested sows, after 8 weeks the litters should be separated; and, in order to prevent subsequent infection, the weanlings should be raised in uninfested hog pens and pastures. Kidney worm-free premises are either those which had not been previously occupied by any swine, had been only used by kidney worm-free pigs, or had been vacated for about 4 mo. In each of the three methods, strict observance of sanitation is imperative. . . .

"Despite the fact that during the gestation period the sows were constantly exposed to infection, there was no case of intrauterine infection; showing that, if this mode of infection ever takes place in stephanuriasis, it may be only in very rare cases. In the control experiment where the suckling pigs were exposed to natural infection soon after birth, gravid female worms were found in the perirenal fat and the urine was positive for ova of kidney worm of pigs ranging in ages from 134 to 146 days. Hence, it is quite conclusive that, due to the tenderness of the tissues of the suckling pigs, the development and the migration of the kidney worms in the bodies of the young hosts were faster than in older pigs.

"In view of these findings, the fact is established that even pigs younger than 6 mo. old, when raised in infested hog pens without regard to sanitation, are as potentially dangerous as the older ones by acting as disseminators of the eggs of kidney worm."

A list of 22 references is included.

**Habronemiasis, J. R. UNDERWOOD** ([*War Dept. U. S.*], *Off. Surg. Gen., Vet. Bul.*, 30 (1936), No. 1, pp. 16-28).—The author has found worms of the genus *Habronema* to be common parasites of Army animals in the United States and in the Philippine Islands. It is pointed out that "*Habronema* larvae, long known to be associated with summer sores in Europe and South America, are the common cause of summer sores in the Philippine Islands and in Texas. Habronemic conjunctivitis of the horse occurs in the United States and in the Philippine Islands. *Habronema* larvae are capable of penetrating moistened, unbroken skin. Examination of the stomach contents of 131 horses and mules failed to confirm the theory that *Habronema* larvae reach the stomach through the swallowing of infested flies. Glycerin combined with fly repellents is effective in the treatment of cutaneous habronemiasis."

**Mercuric chloride test for infectious anemia, J. D. DERRICK** ([*War Dept. U. S.*], *Off. Surg. Gen., Vet. Bul.*, 30 (1936), No. 3, pp. 197-199).—The author's study leads him to doubt if the mercuric chloride test is of definite diagnostic value for infectious anemia of the horse.

**Equine infectious anemia in New England, R. A. KELSEY** ([*War Dept. U. S.*], *Off. Surg. Gen., Vet. Bul.*, 30 (1936), No. 3, pp. 193-196).—Cases are here reported which show that infectious anemia of horses has occurred and does occur in the New England States.

**Report of an outbreak of equine infectious anemia, with observations on blood changes, C. A. GRIFFIN and C. P. BROSE** (*Jour. Amer. Vet. Med. Assoc.*, 89 (1936), No. 6, pp. 664-670, figs. 2).—Clinical observations and laboratory findings during a small outbreak of equine infectious anemia in New York State

are reported. Attention is called to the fact that this disease is not always recognized and that it presents a serious problem to owners of large groups of horses. The changes in the blood and the time of their occurrence in relation to the elevation of temperature are reported upon.

[Equine dhobie itch a symptom of filariasis], J. R. U[NDERWOOD] ([War Dept. U. S.], *Off. Surg. Gen., Vet. Bul.*, 30 (1936), No. 1, pp. 71-77, figs. 2).—These notes supplement the previous data (E. S. R., 74, p. 699).

Equine encephalomyelitis, J. D. DERBICK ([War Dept. U. S.], *Off. Surg. Gen., Vet. Bul.*, 30 (1936), No. 3, pp. 174-192).—Experimental studies and observations of virus-borne epizootic equine encephalomyelitis are outlined. These comprise observations of symptoms, macroscopic and microscopic pathology, transmission experiments, and attempts at immunization and therapy with antiserum.

It is concluded that "the disease affects horses of all ages, regardless of physical condition. The virus is readily isolated from brains of affected horses before death, but appears in the blood stream only during the early febrile phase. Cultures from typical cases were sterile except for an occasional non-specific streptococcus. The symptoms are those of a progressive involvement of brain and spinal cord, usually of two types, the lethargic or excitable. Subcutaneous injections of virus did not result in consistent reproduction of the syndrome. Cisternal and epidural inoculations of spinal virus regularly reproduced the specific disease."

A report is made of the preparation of vaccines after the methods of Laidlaw-Dunkin and of Kolmer, and the simultaneous immunization of horses with specific antiserum and virus.

Epizootic fox encephalitis.—VII, The occurrence of the virus in the upper respiratory tract in natural and experimental infections, R. G. and B. B. GREEN, W. E. CARLSON, and J. E. SHILLINGER (*Amer. Jour. Hyg.*, 24 (1936), No. 1, pp. 57-70, figs. 3).—Further studies (E. S. R., 73, p. 244) have shown that "the virus of fox encephalitis can be identified in the upper respiratory tract by injection into foxes of filtered nasal washings. Using this technic, the natural spread of the disease was studied in a group of experimental red foxes. Following the initial spread of the infection, a second spread was occasioned by artificially increased contact. Subsequent to a closed serum-virus injection, the virus appeared in the upper respiratory tract of only those animals which developed delayed infections. All studies seem to show a high affinity of the virus for the upper respiratory tract. The specific inclusions of fox encephalitis were demonstrated in cells associated with the surface epithelium of the upper respiratory tract. In definite ulcers nearly all cells contained the inclusion bodies. It would seem evident that the upper respiratory tract is the portal of entry for the fox encephalitis virus, and that the virus gains entrance by direct involvement of surface cells. The development of virus in the upper respiratory tract after a closed intramuscular injection of the virus appears to be due to the involvement of surface epithelium as a part of the general infection. It is indicated that persistence of the virus in the surface cells of the upper respiratory tract is responsible for the carrier state which has been obvious in epidemiological studies."

Diseases of poultry, with special reference to those occurring in Cyprus, R. MOYLAN GAMBLES (*Cyprus Agr. Jour.*, 31 (1936), No. 1, pp. 12-19).—The more important diseases and parasites of poultry in Cyprus are briefly considered.

The genus *Capillaria* Zeder 1800 [Nematoda, Trichuroidea] and the capillarioses in poultry, J. F. TEIXEIRA DE FREITAS and J. LINS DE ALMEIDA (*Rev. Dept. Nac. Prod. Anim. [Brazil]*, 2 (1935), No. 4-6, pp. 311-384, figs. 49; *Eng. abs.*, p. 363).—This contribution includes descriptions and the synonymy

of 10 species of *Capillaria* found in domestic fowl, a domestic host list, and a bibliography of 141 titles.

**Laryngotracheitis, one of the poultry diseases previously called "raup",** T. G. HUNGERFORD (*Agr. Gaz. N. S. Wales*, 47 (1936), Nos. 2, pp. 112-114, Nos. 3; 3, pp. 163-165, Nos. 3; 4, pp. 223-225, Nos. 2).—A summary of information is given on this disease of poultry, widespread in New South Wales and the cause of great economic loss.

**A study of transmissible fowl leukosis,** C. OLSON (*Jour. Amer. Vet. Med. Assoc.*, 89 (1936), No. 6, pp. 681-705, Nos. 11).—The author found fowl leukosis to be transmissible to susceptible chickens by means of whole blood, blood plasma, and tissue emulsions. "The inciting agent remains viable in glycerin solution and is filtrable. The disease is not transmissible to ducks, geese, or turkeys. The disease produced by the inciting agent is manifest by certain specific pathologic changes in the erythrocytic and granulocytic hematopoietic tissues, and in most instances by the appearance of pathologic cells in the peripheral blood. The transmissible agent of fowl leukosis is not responsible for the conditions known as lymphocytoma or neurolymphomatosis gallinarum. The changes in the blood in transmissible fowl leukosis are variable quantitatively and qualitatively. Transfusions with chicken blood and oral administration of arsenic in the form of Fowler's solution are of no avail in the treatment of the well established form of the disease."

**Pullorum disease in captive quail,** M. W. EMMEL (*Jour. Amer. Vet. Med. Assoc.*, 89 (1936), No. 6, pp. 716, 717).—An investigation was made by the Florida Experiment Station of losses which occurred throughout the 1936 growing season in young quail on a farm maintaining about 300 pairs of breeding birds. Cultures made from the organs of 2 of 5 affected quail chicks examined yielded a micro-organism having the characteristics of *Salmonella pullorum*. The infection appeared to have been introduced to the premises of the farm by birds raised in captivity that had been received in March, the infection having been spread to a considerable extent by means of the incubators. It is pointed out that while it is unlikely that pullorum disease is of particular importance in wild quail at this time, the release of pullorum-infected birds from quail farms is a potential menace to the future welfare of this game bird, particularly at this time, when the restocking of the wild supply is a conservation program of many States.

## AGRICULTURAL ENGINEERING

**Report of the Chief of the Bureau of Agricultural Engineering, 1936,** S. H. MCCROBY (*U. S. Dept. Agr., Bur. Agr. Engr. Rpt.*, 1936, pp. 24).—The progress results of investigations of duty of water, evaporation, silt in streams, pumping, underground storage, irrigation in the humid region, drainage of peat soils and sugarcane lands, curing concrete for resistance to alkali, farm-operating efficiency, heating of farmhouses, potato storage, cotton, corn, and sugar beet production machinery, combines for harvesting soybeans, a pyrethrum harvester, fertilizer-distributing machinery and practices, pest-control equipment, cotton gins, and drying seed cotton, conducted during the fiscal year 1936, are briefly presented.

[Agricultural engineering investigations by the Colorado Station] (*Colorado Sta. Rpt. 1936*, pp. 24, 35-37, 38).—Progress results are briefly presented of investigations on sugar beet machinery, the design and development of irrigation equipment, and irrigation water supply forecasting.

[Agricultural engineering investigations by the Texas Station], R. E. DICKSON, B. C. LANGLEY, H. P. SMITH, D. T. KILLOUGH, D. L. JONES, B. H.

HANCOCKSON, R. W. BARN, and P. L. HOPKINS (*Texas Sta. Rpt. 1935*, pp. 63, 64, 132-135, 152-153, 179-182, 199, 200).—The progress results are briefly presented of investigations on mechanical harvesting of cotton, mechanical snapping of cotton bolls, factors of efficiency in the distribution and placement of cottonseed and fertilizer, calibration of cotton planters, planting of cottonseed at varying and uniform depths, run-off water losses in relation to crop production, and soil erosion control by agronomic and engineering methods.

Surface water supply of the United States, 1935, Parts 4, 7, 11, 13, 14 (*U. S. Geol. Survey, Water-Supply Papers 784* (1936), pp. 170, pl. 1; 787 (1936), pp. 150, pl. 1; 791 (1936), pp. 361, pl. 1; 793 (1936), pp. 197, pl. 1; 794 (1936), pp. 167, pl. 1).—These papers present the results of measurements of flow made on streams during the year ended September 30, 1935, No. 784 covering the St. Lawrence River Basin; No. 787, the lower Mississippi River Basin; No. 791, the Pacific slope basins in California; No. 793, the Snake River Basin; and No. 794, the Pacific slope basins in Oregon and lower Columbia River Basin.

Water levels and artesian pressure in observation wells in the United States in 1935, O. E. MEINZER and L. K. WENZEL (*U. S. Geol. Survey, Water-Supply Paper 777* (1936), pp. III+268).—This report consists of a group of papers, prepared chiefly by members of the Geological Survey, relating for the most part to the work of the Geological Survey and cooperating Federal, State, county, and local agencies in obtaining records of water levels and artesian pressure in observation wells in 25 States and the Territory of Hawaii. It is planned to be the first of a series of annual reports on the fluctuations of the ground-water levels and artesian pressures in the United States.

Artesian water in the Florida peninsula, V. T. STRINGFIELD (*U. S. Geol. Survey, Water-Supply Paper 773-C* (1936), pp. IV+115+195, pls. 11, figs. 9).—This report is based on the results of a general survey, the essential data being presented largely in graphic form.

Ground-water resources of Kleberg County, Texas, P. LIVINGSTON and T. W. BRIDGES (*U. S. Geol. Survey, Water Supply Paper 773-D* (1936), pp. II+197-232, pls. 5, fig. 1).—This report presents the results of an investigation of the geology and ground water resources of the area.

Equipping a small irrigation pumping plant, W. E. CODE (*Colorado Sta. Bul. 433* (1936), pp. 55, figs. 25).—Practical information of a technical character is presented on the subject, together with data on the cost of pumping. Appendixes give data on the economical sizes of pipe and on pump selection.

Application of rainfall intensity-frequency data, D. L. YARNELL (*Agr. Engin.*, 17 (1936), No. 9, pp. 386, 391, figs. 2).—This is a brief discussion from the U. S. D. A. Bureau of Agricultural Engineering.

Subsoil waters of Newlands (Nev.) Field Station, C. S. SCOFIELD, C. L. MOON, and E. W. KNIGHT (*U. S. Dept. Agr., Tech. Bul. 533* (1936), pp. 31, fig. 1).—The purpose of this report is to discuss conditions in respect to the subsoil water that constitutes one of the features of the problem of crop production not only on the Newlands Field Station but elsewhere on the Newlands reclamation project. The observations were made by means of a number of wells, 83 in all, comprised in 5 groups. The records include weekly observations of elevation in the wells of some groups and monthly observations in the others.

The saturated zone has a surface gradient to the south and east approximately conformable to the ground surface and equivalent to approximately 5 ft. per mile. The mean annual range in elevation from the low of early spring to the high of midsummer is somewhat less than 8 ft. The evidence of the water-elevation data indicates that the subsoil water is intercommunicating throughout the area of the field station, yet notwithstanding the

appreciable gradient of its surface there does not appear to be lateral movement in the mass at a measurable rate.

The salinity of the subsoil water has been determined by samples from the wells taken monthly or less frequently throughout the year. There are pronounced differences in the salinity of the water obtained from the different wells, and in general these differences remain fairly constant.

Changes in elevation of the subsoil water occur approximately simultaneously in adjacent wells, thus indicating hydrostatic intercommunication, but the persistent differences in salinity between adjacent wells indicate that there is a very slight general lateral movement of the water.

Observations have been made also on the salinity of the irrigation water and on that of the water collected by an open drain contiguous to the station. These observations show that the mean concentration of the subsoil water is from five to six times as high as that of the irrigation water, while the concentration of the drainage water is intermediate between these two.

Taken as a whole the evidence from these observations indicates (1) that the subsoil water is replenished in part by percolation from the unlined canals of the distribution system and in part by the downward percolation of the irrigation water applied to the land, and (2) that the lateral movement in the direction of the surface gradient of the saturated zone does not occur uniformly but rather through the more permeable sections of the subsoil.

The hydrostatic readjustments by which the seasonal changes in elevation are kept uniform appear to be transmitted through or around the less permeable sections of the subsoil and to be accomplished with very little movement in the mass of the subsoil water.

In some areas of the station the salinity and the boron content of the subsoil are so high as to retard or even to inhibit the growth of crop plants when this water invades the root zone of the soil.

**Watershed and hydrologic studies in soil conservation, C. E. RAMSER** (*Agr. Engin.*, 17 (1936), No. 9, pp. 373-376, figs. 3).—This is a brief discussion of these studies as they are being carried on by the U. S. D. A. Soil Conservation Service. Their objectives are (1) to determine the effect of erosion control practices and land use upon the conservation of water for agricultural purposes, such as irrigation and domestic farm supplies, and for public utility purposes, such as water power and urban water supplies; (2) to determine the effect of erosion control practices and land use upon the control of floods that destroy crops, damage soil fertility on agricultural bottom lands, and cause damage to or destruction of municipal property; and (3) to determine the rates and amounts of run-off and eroded soil material from rains of different amounts and intensities for use in the economic design of erosion control and flood control structures. This information will also be of value in determining to what extent eroded material can be prevented from entering and reducing the capacity of drainage channels and reservoirs by the application of proper land use and erosion control practices.

**Sheet erosion studies on Cecil clay, E. G. DISEKER and R. E. YODER** (*Alabama Sta. Bul.* 245 (1936), pp. 52, figs. 9).—This bulletin presents the results of 6 years' experimentation on the measurement and control of the sheet erosion process on Cecil clay. Its purpose is to present methods and procedure by which some of the basic principles involved in sheet erosion control may be analyzed and to apply these principles to Cecil clay. A set of 10 controlled plats, each 15 by 50 ft., was used, with two plats located on each of a 0, 5, 10, 15, and 20 percent slope. Experiments were conducted under wide variation of soil condition and vegetative cover.

The moisture content of the soil influenced the rate and extent of absorption and hence influenced run-off and soil movement during any given rain. A large portion of seasonal erosion losses invariably resulted from a few heavy rains which occurred when the soil was approximately saturated.

Rainfall intensity was more important than the quantity of rainfall in determining the amount of erosion when other conditions were held constant and when the rate of rainfall exceeded the rate of infiltration to an extent that appreciable run-off occurred. With a given intensity of rainfall, the greater the duration the greater the soil losses. Losses from intermittent rains of a given quantity were decidedly less than those from rains of continued duration, provided the rate of rainfall exceeded the rate of absorption. This was due to the inability of the soil to absorb the quantity of water during a given time. The exception to this was on smooth fallow, in which case the soil losses per unit of run-off decreased because the loose or slaked soil was readily carried off by the first part of the rain.

Pulverization and tillage practices which increased the rate and amount of absorption were very effective in controlling sheet erosion, provided the rate and amount of rainfall did not exceed the rate and amount of absorption. When the rate of rainfall greatly exceeded the rate of infiltration, excessive soil losses usually resulted from such tillage practices.

Aggregate analysis of sediments eroded from Cecil clay under a wide variety of conditions showed that the unit particles involved in the sheet erosion process, in the case of structural soils, were aggregates rather than textural separates. In general, soil material is moved layer by layer in the sheet erosion process. The relative loss of colloidal material may be excessive under a condition or combination of conditions which results in small quantities of run-off or in run-off of low velocity, or both.

Winter cover crops and other vegetative control measures functioned in reducing sheet erosion losses and soil movements by (1) filtering out the large soil particles and water stable aggregates, (2) decreasing the quantity of run-off, (3) decreasing the velocity of run-off, (4) minimizing the turbulence of run-off and hence lessening the abrasive or dispersive action of sediment-loaded water, and (5) by decreasing the mechanical dispersive action of beating rainfall.

Annual soil losses from land continuously in cotton were reduced to about one-half by the use of vetch as a winter cover crop. Rye, used as a winter cover crop, was nearly as effective as vetch in reducing erosion losses. Various width strips of soil-conserving crops were effective in reducing erosion and in decreasing the distance of soil movement on between-terrace slopes. It seems that if strip cropping is practiced, it should be used as a supplement to terraces rather than as a substitute for terraces.

Contoured, row-crop plantings had a pronounced soil- and water-saving ability when compared to slope plantings. The amount of soil eroded from slope-planted cotton was about twice as much as that from contour-planted cotton.

Erosion losses increased with increased slope under all conditions studied. The so-called "critical slope" or point above which a given soil cannot be cropped without excessive erosion losses is more dependent upon such factors as plant coverage and tillage practices than on topography itself.

Conditions influencing erosion on the Boise River watershed, F. G. RENNER (*U. S. Dept. Agr., Tech. Bul. 528 (1936), pp. 32, figs. 14*).—This bulletin presents an analysis of the data collected during an intensive survey of erosion and related factors on the most seriously affected parts of the drainage within

the Boise National Forest for use as a guide in planning protection and management of this and other watershed areas where similar conditions prevail.

With other factors equal, the amount and severity of the erosion was found to vary directly with gradient. Actually, however, the erosion increased as the gradient increased only up to approximately 85 percent; beyond this point, because other factors are not equal on steeper areas, the erosion decreases. On the steeper slopes, these factors, chiefly lighter grazing by livestock, are sufficiently powerful to reverse completely the trend toward increased erosion with increased gradient.

The causes of erosion were found to be most operative on southerly aspects. On northerly exposures, differences in temperature and moisture conditions gradually have brought about a vegetation cover which is more effective in its ability to hold the soil and prevent erosion. This vegetation in turn, and to a greater extent than on southerly aspects, has improved soil conditions through additions to the litter and organic matter. Moreover, the maintenance of these improved conditions on northerly aspects has been favored by lighter rodent infestations and less use by livestock.

Serious losses of the topsoil have occurred over extensive areas. With their normally coarse texture and comparative lack of binding properties, even the soils where this top layer can still be found erode easily. The loss of litter and organic matter through the removal of the top layer has still further reduced the soil's resistance to erosion and therefore has aggravated the effect of the factors of steepness, scant vegetation, rodent infestation, and overgrazing.

Erosion conditions differ sharply on the various range types. The weed and grass types in particular have suffered severely, and even in the sagebrush, browse, and timber types much damage has been done. The more seriously eroded types are those whose soil conditions have been the most disturbed by rodents and grazing.

A vegetation cover of less than 30 percent appears to have little appreciable effect in retarding erosion. This scant cover is found on more than one-half of the watershed. As the density of the vegetation increases above 30 percent the erosion rapidly decreases, and apparently a cover of 40 percent is sufficient to prevent gully erosion under normal conditions of grazing use.

Rodents have partially depleted the vegetation and disturbed the soil over four-fifths of the area studied. In addition, their effect upon erosion has probably been increased by their habits of concentration on southerly exposures and other areas which are heavily grazed by livestock.

The erosion was found to vary directly with the degree to which the vegetation cover has been depleted and the surface conditions disturbed by the grazing of livestock. Almost without exception, the areas which have been grazed most heavily are examples of the most severe erosion. On an area with the steep slopes, loose, coarse soil, and scant vegetation characteristic of this watershed, the degree of use by livestock appears to be of far more importance in its effect upon erosion than any other of the factors studied.

**The use of bluegrass sod in the control of soil erosion,** R. E. UHLAND (*U. S. Dept. Agr., Farmers' Bul. 1760 (1936), pp. 11-13, figs. 9*).—This supersedes Leaflet 82 (*E. S. R., 60, p. 672*), and is designed to further familiarize farmers with the various ways in which bluegrass may be used as a means of gully control.

**New developments in terracing in the Southeast,** M. L. NICHOLS (*Agr. Engin., 17 (1936), No. 9, pp. 393, 394*).—In a brief contribution from the U. S. D. A. Soil Conservation Service a summary of observations is given to indicate trends in engineering practice in soil erosion control in the Southeast. It is pointed

out that the general trend of this development is toward a coordinated program in which terracing is an important part.

**A method of measuring acres per mile of terrace and total acres benefited.** V. R. HILLMAN (*Agr. Engin.*, 17 (1936), No. 2, pp. 395, 408).—This paper from the U. S. D. A. Soil Conservation Service describes a method of determining both the acres per mile of terrace and the actual area benefited by any number and length of terraces in a field or in a system of parallel terraces.

**Determining the percentage of moisture in soil samples without drying.** E. E. BAUER (*A. S. T. M. [Amer. Soc. Testing Materials] Bul.* 81 (1936), pp. 10, 11, 13, figs. 2).—This paper is a report of efforts made at the University of Illinois to adapt procedure for the determination of the constituents of freshly made concrete to the determination of the moisture content of soils. It explains briefly the theory involved, describes the equipment and test procedure, and gives the results of tests and check tests of oven-dried samples.

**Representing the distribution of ground stresses.** K. FISCHER (*A. S. T. M. [Amer. Soc. Testing Materials] Bul.* 81 (1936), pp. 12, 13, figs. 6).—This is a brief description of a method recently developed in Austria that enables representation of the distribution of stress in homogeneous masses of sand in a simple manner. The results have application to all soil dynamics work.

**Control of high soil temperature.** I. E. P. SMITH (*Agr. Engin.*, 17 (1936), No. 2, pp. 383-385, figs. 7).—This is a contribution from the Arizona Experiment Station relating to the development of methods for the control of high soil temperatures in the hot semiarid regions.

It was found that the cooling of the soil is due primarily to the evaporation of water on or near the soil surface. Apparently the initial temperature of the irrigation water is a minor factor. For comparison with the method of frequent irrigations, preliminary trials of other methods of soil cooling were conducted. A gray tar paper appeared to have no effect, and a loose earth mulch had very little effect. A mulch of alfalfa straw lowered the temperature 5° until the next irrigation, after which the advantage was only about 2°. Data obtained from four plots of 39 nursery trees each showed that soil under roofing paper was the hottest and soil under dry straw mulch was the coolest. The minimum daily temperature at 1 ft. depth occurred at noon.

**Oiled-gravel roads of Colorado.** E. B. HOUSE (*Colorado Sta. Bul.* 426 (1936), pp. 29, pl. 1, figs. 3).—From several years' experimentation it has been found that conditions necessary for first-class oiled roads are (1) a well-compacted, dry subgrade, (2) adequate drainage, and (3) even distribution of oil throughout the matrix. To accomplish the last, the use of mixing machines in which the oil is under constant control is considered essential. Water in the aggregate up to 6 percent improves the matrix and provides a stronger and better wearing road surface if the materials are well mixed. A fine material in the aggregate is considered to be of special importance and should amount to not less than 10 percent.

Formulas from various sources for mixes are presented and discussed.

**Public Roads.** [November 1936] (*U. S. Dept. Agr., Public Roads*, 17 (1936), No. 9, pp. 203-221+[1], figs. 10).—This number of this periodical contains data on the status of various highway projects as of October 31, 1936, and an article entitled *The New York Financial Survey*, by E. C. Paddock (pp. 203-218).

**Gasoline and alcohol-gasoline blends.** L. T. BROWN and L. M. CHRISTENSEN (*Indus. and Engin. Chem.*, 28 (1936), No. 6, pp. 650-652, figs. 7; also in *Proceedings of the Second Dearborn Conference of Agriculture, Industry, and Science, Dearborn, Mich., 1936. Dearborn: Farm Chemurgic Council, 1936. pp. 398-403, figs. 7*).—Tests are reported which were conducted at the Iowa Experiment Station with gasoline and a blend containing 10 percent of ethanol and 90 percent

of the same gasoline. The tests were conducted with a six-cylinder truck or bus engine of 4-in. bore and 5-in. stroke, developing its maximum power at about 2,800 r. p. m. The compression ratio was 4.85:1. The gasoline used was a 65-66 octane rating regular grade gasoline.

Less cooling water was required with the blend than with the gasoline as the fuel to maintain an outlet temperature of 150° F. There was no significant difference in the temperatures in other parts of the engine in shifting from one fuel to the other. The air-fuel ratio with a given speed, throttle opening, and carburetor jet was practically identical with the two fuels. The ratio with the blend was slightly lower with the 0.056-in. jet and slightly higher with the 0.068-in. jet. In effect, the substitution of the blend resulted in a mixture ratio slightly weaker than that obtained with gasoline under the same conditions.

The air-fuel ratios varied from 11-1 to 16-1. Within this range the power output is ordinarily increased by a decrease in the air-fuel ratio. Except at the higher speeds and with the highest air-fuel ratios, the blend gave a greater power output than did the gasoline. This result was obtained in spite of the fact that the mixture ratio was, in effect, smaller with the gasoline.

The blend gave appreciably less carbon monoxide under a given set of conditions than did the gasoline, but there was no definite ratio. In general, the decrease in carbon monoxide production could be accounted for on the basis of the difference in oxygen requirements of the two fuels. That is, if the two fuels were used with mixture ratios containing the same ratio of oxygen required to oxygen present, the carbon monoxide content of the exhaust gas would be the same for the two fuels.

The relative power output with the gasoline and the blend was affected by air-fuel ratio and engine speed, whereas the throttle position apparently had little or no influence upon the relative values. With the highest air-fuel ratios (15 or 16:1) and the higher engine speeds (1,600 to 2,000 r. p. m.) the blend was inferior to gasoline, but with the lower air-fuel ratios, and particularly at low engine speeds, the blend gave the greater power output.

In general, the blend was favored by low air-fuel ratio, low engine speed, and small throttle opening. There was no single relation between the relative specific fuel consumptions with the two fuels.

The data indicate that the carburetor setting with the gasoline and the 10-percent blend should be the same for satisfactory practical operation. Operations at low speed and at part throttle were particularly favorable as regards comparative advantage of the blend over gasoline, under which conditions the 10-percent alcohol blend gave slightly greater power output, appreciably lower specific fuel consumption, and a 30 to 50 percent lower carbon monoxide production than was obtained with the gasoline alone.

**Calibration of cotton planting mechanisms, H. P. SMITH and M. H. BYROM (Texas Sta. Bul. 526 (1936), pp. 32, figs. 22).**—Tests were made on cell-drop and picker-wheel drop cotton planting mechanisms to determine the quantity of cottonseed planted per acre and the percentage of seed hulled in passing through the different types of planting mechanisms.

The smallest number of cottonseed dropped per acre by the cell-drop planting mechanisms tested was 39,776 at low-plate speed, while the largest number was 254,724 seed at high-plate speed. This is equivalent to 8.61 and 55.16 lb., or approximately 0.25 and 1.75 bu., per acre.

Picker-wheel drop planting mechanisms had a wider spread than the cell-drop planting mechanisms between the minimum and maximum quantities of seed dropped, ranging from 33,996 to 549,064 seed per acre. The equivalent in pounds is 7.36 and 118.87, or approximately 0.25 and 3.5 bu. per acre.

The size of the seed materially influenced the quantity of seed dropped. When the same plates and speeds were used to drop medium-sized Truitt cottonseed, from 47,569 to 87,043 more seed were planted per acre than with the larger-sized Ducona seed. Seed dropped by picker-wheel drop mechanisms ranged from 43,085 to 151,068 more medium-sized Truitt seed than large Ducona seed per acre.

The percentage of seed hulled by cell-drop planting mechanisms ranged from 0.001 to 1.47 percent. The highest percentage of seed hulled by picker-wheel drop planting mechanisms was 0.46 percent.

If 70 percent of the smallest and largest number of seed dropped by cell-drop planting mechanisms germinated, the number of plants obtained would range from approximately 2 to 12 per foot. To obtain a perfect stand of 14,520 plants per acre, from 1 to 11 plants per foot would have to be thinned out. The number of plants per foot for picker-wheel drop mechanisms ranged from 2 to 27, requiring the removal of from 1 to 26 plants per foot to leave 1 plant per foot.

**Rubber as a protective device on concave teeth for threshing seed beans,** B. L. WADE and W. J. ZAUMEYER (*Jour. Amer. Soc. Agron.*, 28 (1936), No. 9, pp. 723-726).—Investigations conducted at Greeley, Colo., by the U. S. D. A. Bureau of Plant Industry for only two seasons and two varietal types of beans indicate that in some cases rubber on the concave teeth may give some slight protection, but probably not enough to justify the expenditure of time necessary to equip the thresher. It is deemed more important to control the cylinder speed of the machine, as well as the distance through which the beans fall after leaving the cylinders and the hardness of the surface upon which they drop.

**The precooling of fresh fruit,** T. E. HENTON and K. I. FAWCETT (*Agr. Engin.*, 17 (1936), No. 9, pp. 377, 378, 382, figs. 5).—In studies conducted by the Indiana Experiment Station cars of strawberries, peaches, and cantaloups from which the field heat had been partially removed and similar check cars without precooling were followed to market destination. Observations of precooled and nonprecooled cars of cantaloups shipped a distance of 500 miles revealed that the precooled ones on the top of the load ripened more slowly than did those not precooled. The fastest rate of cooling cantaloups was obtained by using two 18-in. disk fans to distribute the cold air. It was found that the container in which the produce is shipped may directly affect the rate of precooling. It appears that if peaches are to be precooled in a reasonable length of time the baskets, pads, and paper liners must be constructed to allow a greater passage of air than is now possible.

**Chopping and storing alfalfa hay,** T. E. HENTON and J. H. HILTON (*Indiana Sta. Circ.* 221 (1936), pp. 4, figs. 2).—Practical information is presented.

**The storage of corn fodder or stover,** E. A. SILVER (*Agr. Engin.*, 17 (1936), No. 9, pp. 392, 394, fig. 1).—In a brief contribution from the Ohio Experiment Station practical information is presented on the chopping of corn fodder and stover for mow storage. In studies made of the behavior of the chopped material in storage peak temperatures occurred approximately on the third and fourth days after the material was placed in the mow. These results in general were similar to those obtained with chopped hay. Following this peak the temperature began to drop slowly, with intermittent rises occurring at various times. At the end of 2 mo. a slight coat of mold had formed on top and around the exposed sides of the pile. Below the layer of mold there was no evidence of spoilage.

**Rules for the aeration of silos** [trans. title], M. R. LEGENDRE (*Génie Rural et Elect. Rurale*, 29 (1936), Sept., p. 30, fig. 1).—In this contribution the term silo

is used to indicate a grain storage. On that basis graphic data are presented indicating the proper ventilation of grain storages for different conditions of humidity and conditions of grain in France.

**Adobe construction**, H. C. SCHWALEN (*Agr. Engin.*, 17 (1936), No. 9, pp. 387-389, figs. 2).—In a contribution from the Arizona Experiment Station data on adobe construction in Arizona are presented, with particular reference to the influence of semiarid conditions.

**Oil burners for home heating**, A. H. SENNER (*U. S. Dept. Agr. Circ.* 406 (1936), pp. 27, figs. 13).—This circular is a revision of and supersedes Circular 405 (E. S. R., 56, p. 598), and relates only to power-operated types of oil burners. Practical information of a technical character is presented.

**Solar energy and its use for heating water in California**, F. A. BROOKS (*California Sta. Bul.* 602 (1936), pp. 64, figs. 29).—This bulletin presents a technical analysis of the subject and reports the results of investigations on water temperatures and the rate of heating water in different solar heating systems.

It was found that enclosed 30-gal. hot-water boilers with glass covers can be used as solar heaters without pipe-absorber coils and will furnish two or three hot showers per tank in the late afternoon or evening of bright sunshiny days. These tank absorbers do not keep their high temperatures over night and are not a satisfactory means of obtaining hot water for washing clothes.

The glass area of the ordinary pipe-coil absorber should be about as large in square feet as the number of gallons of storage-tank capacity. The 0.75-in. pipes are conveniently spaced about 2.75 or 3 in. center to center and usually should be arranged in parallel circuits to avoid excessive temperature rise. The length of single pipe of about 70 to 100 ft. when the absorber discharges into the storage tank about 7 ft. above the center of the absorber gives over 80° F. temperature rise, which is adequate. When the tank inlet is lower the single-pipe length should be reduced in proportion.

The insulated storage tank used with regular pipe-coil absorbers should have a capacity equal to the whole day's hot water demand, because about half of the hot water is often used after sunset and about half is often needed early in the morning before the sunshine has time to heat much water.

To insure a constant supply of hot water regardless of the weather, the hot outlet pipe from the solar-heater storage tank can be connected to the cold inlet of an automatic auxiliary heater. Then if the solar-heated water is not up to thermostat-control temperature the automatic heater will operate to raise the temperature to the desired point. When there is good sunshine the water entering the automatic heater whenever a faucet is opened will already be hot enough, and the auxiliary heater need not operate.

**Industrial wastes in New Jersey**, W. RUDOLFS and L. R. SETTER (*New Jersey Stat. Bul.* 610 (1936), pp. 22).—The results of an industrial waste survey covering the more highly industrialized areas of New Jersey are briefly summarized. The number of industries visited amounted to 1,792, and definite waste information was obtained from 1,213 industries. Since many industries were duplicated, samples of 401 were obtained, 251 of which were completely analyzed and 150 partly analyzed for confirmation. The water consumption from which the samples were collected amounted to 54,600,000 gal. a day, and the liquid wastes discharged amounted to 43,651,000 gal. a day.

The quantity of wet suspended solids (5 percent) produced by the industries amounts to 700,000 tons a year as compared to 900,000 tons of sewage solids. The settleable solids, effective in sludge bank formation, amount to nearly 100,000 tons as compared with about 450,000 tons of sewage sludge. On the basis of oxygen consumption the estimated population equivalents for the in-

dustries in the State amount to over 3,000,000, or as much as two-thirds of the total domestic waste produced by the entire population of the State. The waste of the different industries varies considerably in solids production and oxygen demand. The oxygen requirements of the waste produced per employee by the different industries were from 2.9 to 470 times greater than the oxygen demand requirements of the sewage of one person, and the suspended solids produced for each employee was from 2.4 to 181 times greater than the suspended solids produced per person as domestic sewage.

### AGRICULTURAL ECONOMICS

[Papers and notes on agricultural economics] (*Jour. Farm Econ.*, 18 (1936), No. 4, pp. 645-770, figs. 7).—Papers are included as follows: The Italian "Battle of Wheat", by C. T. Schmidt (pp. 645-656). The Need for "Generalists", by A. G. Black (pp. 657-661); Rural Cooperative Credit Unions, by E. C. Johnson (pp. 662-672); Our Farm Credit System, by H. H. Preston (pp. 673-684); How Hogs Are Transported to Market in the Corn Belt, by K. Bjorka (pp. 685-694); Interrelationships of Livestock Production and Cropping Systems on Iowa Farms, by W. W. Wilcox (pp. 695-705); Monthly Poultry Costs and Returns, by K. T. Wright (pp. 706-710); Some Problems of County Government, by M. P. Catherwood (pp. 711-723); Farm Land Values as Affected by Road Type and Distance, by C. L. Stewart (pp. 724-735); and Technical Conditions Are Important Factors in Short-Time Movements of Wheat Prices, by H. S. Irwin (pp. 736-742).

Notes as follows are also included: Combination of Factors of Different Efficiency, by W. C. Waite (pp. 743-745); The National Income, and What Do We Know About It? by O. C. Stine (pp. 745-747); The Need for Area Index Numbers, by J. D. and G. Black (pp. 748-750); Farm Management Research and Changing Price Relationships, by J. C. Bottum (pp. 750-755); Do Present Trends in the Teaching of Economics Jeopardize the Future Value of Research? by D. N. Donaldson (pp. 755-758); Some Effects of Maintaining Retail Prices of Whole Milk at Artificial Levels, by J. T. Palmer (pp. 759-761); The Relation of AAA Reductions to Gold Prices and Purchasing Power of Cotton, by P. A. Eke (pp. 761-765); The Cost of Terracing Farm Land Cooperatively, by G. H. Ward (pp. 765-768); and The Grain Monopoly in Czechoslovakia, by S. Bordaevski (pp. 768-770).

Report of the Chief of the Bureau of Agricultural Economics, 1936, A. G. BLACK (*U. S. Dept. Agr., Bur. Agr. Econ. Rpt.*, 1936, pp. 22).—Data are reported on the agricultural balance, recent trends in farm income, and the farm real estate situation.

[Investigations of agricultural economics by the Ohio Station] (*Ohio Sta. Bimo. Bul.* 183 (1936), pp. 140-142).—The table of index numbers of production, prices, and income, by J. I. Falconer (*E. S. R.*, 76, p. 259) is brought down through August 1936. An article by H. R. Moore on The Farm Foreclosure Situation includes tables showing the number of foreclosures, acreage, amount of judgments, and valuation and sales consideration for lands by semiannual periods July 1933 to June 1936, and the number, total, and per thousand farms of farm foreclosures and voluntary assignments to financial institutions in lieu of foreclosure in Greene, Putman, and Union Counties by years 1925 to 1936 and from January to June 1935 and 1936.

Current Farm Economics, Oklahoma, [December 1936] (*Oklahoma Sta., Cur. Farm Econ.*, 9 (1936), No. 6, pp. 127-150, figs. 2).—Included in addition to the usual tables of index numbers are articles on Outlook for Demand and Prices of Farm Products in 1937, by T. R. Hedges (pp. 128-131); Oklahoma

**Farmers' Recommended Adjustments in Their Farm Organizations to Conserve Soil Fertility and Control Erosion**, by H. A. Miles (pp. 131-133); **Some Trends in the Farm Mortgage Credit Problem**, by O. D. Duncan (pp. 137-142); and **A Study of Man Labor Requirements on Garfield County Farms**, by P. Nelson and E. A. Tucker (pp. 142-147).

[Investigations in agricultural economics by the Texas Station, 1934-35] (*Texas Sta. Rpt. 1935*, pp. 10, 11, 107-116).—Results of investigations not previously noted are reported on the organization and management of farms in the high plains cotton area of the State, by C. A. Bonnen, in cooperation with the Bureau of Agricultural Economics, U. S. D. A.; on quality as a factor in the marketing of vegetables in the lower Rio Grande Valley, by W. E. Paulson; and on costs and services of local government in the State, by L. P. Gabbard and H. C. Bradshaw.

**Land systems and land policies in Nebraska**, A. E. SHELTON (*Nebr. State Hist. Soc. Pub.*, 22 (1936), pp. XVI+383, [pls. 3, figs. 68]).—This is a history of Nebraska land—public domain and private property—from the aboriginal period to 1936. "Nebraska land history exemplifies and illustrates, in conspicuous degree, the results of past and present land systems in the United States of America." The more important data are included under the following chapter headings: Indian land tenure and its extinction; the preemption and land warrants period, 1854-63; homestead, railroad land grant, and agricultural scrip period, 1863-72; the land "boom" period, 1873-91; new land policies, 1891-1902; reclamation and Kinkaid homestead period, 1902-32; westward extension of farming; the conflict between the cattlemen and the grangers; national politics and Nebraska land frauds; Indian reservation lands; State lands; mortgages and lands; results of land policies in Nebraska; new land policies, Nebraska and national; and a final survey.

**An economic study of land utilization in Chenango County, New York**, H. S. TYLER ([*New York*] *Cornell Sta. Bul.* 654 (1936), pp. 63, figs. 18, map 1).—This bulletin is the sixth in the series previously noted (E. S. R., 75, p. 861).

The area and its agriculture are described. The lands of the county are classified according to intensity of present and probable future use, and the land use, soils, real estate values, etc., are noted and comparisons made of farm businesses on the different classes of land. The development of roads, rural mail delivery service, rural electrification, and reforestation are also discussed.

Land in class I comprises about 23 percent and that in class II about 17 percent of the area of the county, and in general is better adapted to forestry and recreational uses than to agriculture. About 54 percent is in land classes III, IV, and V, and probably will remain permanently in agriculture. Approximately 75 percent of the area of land class I and more than 40 percent of that of land class II is idle or in woods. In the higher land classes, a relatively large percentage is in intertilled crops and legume hays. About 10 percent of the soils in the county are valley and intermediate soils, and mostly well adapted to the production of intensive crops. The large area of upland soils supports a less intensive type of farming.

An analysis of 619 labor-income records showed that the average farm business in the higher land classes was larger and more efficient. Full value per acre of land and buildings ranged from \$8 in land class I to \$57 in land class V. Towns with a high average land class tended also to have high values per acre for land and buildings in each land class.

In 1933, about 401 miles of road or approximately one-fourth of the road mileage in the county, had been hard-surfaced. An additional 115 miles had been sub-based. It is suggested that about 325 more miles be improved as

hard roads. "If these were constructed, most of the farms and rural residences in land classes III, IV, and V would be on hard roads. About 500 miles of road will be needed only for forest and recreational travel if land classes I and II are reforested. Rural mail carriers travel almost 50 percent of the mileage of usable roads and serve about 60 percent of all occupied farms and 75 percent of all occupied rural residences in the county. In land classes I and II, 43 percent of the farms had rural delivery, as compared with 67 percent in land classes III to V. . . .

"Approximately 30 percent of the farms and 40 percent of the rural residences in land classes III, IV, and V were connected to electric distribution lines in 1933. It took about 280 miles of line to supply this service. About 505 miles of extensions have been suggested to make service available to all farms and rural residences in land classes III, IV, and V."

On January 1, 1936, about 48,500 acres in the county had been purchased or were under contract by the State for reforestation purposes.

**English farming, past and present, LORD ERNLE** (*London and New York: Longmans, Green & Co., [1936], 5. ed., pp. XVI+559, fig. 1.*).—This is a new edition of the work previously noted (E. S. R., 57, p. 885), edited by A. D. Hall. The history of tithes has been brought down to the present time. The chapters on adversity, 1874-1912, uncertainty, and peacetime farming, 1919-27, have been rewritten or replaced by chapters on the great depression and recovery, 1874-1912, agricultural legislation since the war, small holdings, education and research, and technical progress since the war. The data included in the appendixes on agricultural population, imports of food, and agricultural statistics have been brought down through 1931, 1935, and 1935, respectively, and a table has been added showing the annual index numbers, 1919-35, of wholesale prices of all articles and prices of agricultural produce, feeding stuffs, and fertilizers.

**A statistical study of commercial egg production in Delaware, R. O. BAUSMAN** (*Delaware Sta. Bul. 202 (1936), pp. 79, figs. 30.*).—This study was made to determine the uneconomical practices and systems of poultry management, with a view to assisting poultrymen in supplanting such practices. Records covering the year ended September 30 were obtained from poultry farms in the 3 largest commercial egg-producing areas in the State, there being 115 records in 1931 and 1933, and 114 in 1932. Records of approximately 100 poultry farms for a period of 3 yr. were also made available by the extension service of the University of Delaware. Data as to prices of eggs, trends of egg production, etc., were obtained from the publishers of The Producers' Price-Current, the Bureau of Agricultural Economics, U. S. D. A., and the Federal Bureau of the Census.

The development and economic position of the poultry industry in the State is described, and analysis is made of the effects on egg production and the costs of production of various factors. Some of the findings were as follows:

Delaware farmers receive from approximately 6 to 10 ct. per dozen more for eggs than do Iowa farmers. An increase of 100 layers per flock reduced the cost of egg production 1 ct. per dozen. An increase of 10 eggs per layer reduces the cost 2.2 ct. per dozen. As high a quality of pullets were produced using 20 lb. of feed per pullet made up of 43.8 percent mash as with 34 lb. of feed made up of 62.3 percent mash and the cost was 30 ct. less per pullet. February-hatched pullets as compared with May-hatched pullets had differentials for the laying periods of 41.4 eggs, 5.5 ct. per dozen in the prices of eggs, and \$1.86 in the value of eggs. The cost of producing eggs was no greater. Pullet flocks produced 51.1 more eggs than did hen flocks. The average price paid for eggs from pullet flocks was 5.5 ct. per dozen higher, the

total value of eggs for the laying period \$1.90 greater, and the cost of producing eggs 4.5 ct. per dozen less. A ratio of hens to pullets of approximately 25:75 is more nearly in keeping with good management than the old accepted ratio of 50:50. Where artificial lights were used the rate of egg production increased during the periods the lights were used but decreased when lights were discontinued, so that the annual rate of production was no greater than where lights were not used. The average price per dozen of eggs was the same in both groups. The cost of production was 1.6 ct. per dozen higher with lights. Chicks from commercial hatcheries were equal in quality and the mortality rate as low as that from chicks hatched from home selected eggs. Range, frequency of changing litter, feeding of wet mash, type of floor in laying house, and construction of the fronts of laying houses appeared to have no influence on the rate of egg production. Feeding green feeds to flocks confined in houses during the winter months, feeding of cod-liver oil, and greater floor space per layer increased egg production moderately. Flocks with a high mortality rate averaged 26.1 eggs less per layer and a depreciation of 17 ct. more per layer, a cost of 5 ct. more per dozen eggs, and a labor income of \$210 less per farm than flocks with a low mortality rate. Source and quality of chicks, date of hatch, rate of feeding, floor space per chick and per layer, range, frequency of changing litter, screening of droppings, and feeding of cod-liver oil and green feeds appeared to have only slight influence on the mortality rate and no influence on the prevalence of poultry paralysis. Heavy culling increased the production per layer, but the cost of production per dozen eggs was approximately 1 ct. greater than where light culling was practiced.

"Laying flocks averaging at least 900 birds, pullets hatched in February or not later than March, a ratio of hens to pullets of approximately 25:75, the limited use of artificial lights, the rearing of pullets on limited feeding of a low mash ration when on range, and a conservative culling policy appears to be the most advantageous economic program for Delaware commercial poultrymen."

An economic study of 99 poultry farms in Maryland, W. E. HAUVER, S. H. DE VAULT, and A. B. HAMILTON (*Maryland Sta. Bul.* 397 (1936), pp. 35, figs. 4).—The records used in this study relate to the calendar years 1931 to 1933 and were obtained by personal interviews with farmers in six counties selected on the basis of the importance of the industry in the county. Analysis is made of the effects on profits of type of poultry enterprise, size of business, eggs produced per hen, capital turnover, use of feed, use of labor, selling price of eggs, and cost of producing eggs.

For the 99 farms the average annual farm income was \$1,171 and the average labor income \$728. Eighty-four farms had plus farm incomes and 67 plus labor incomes. The average receipts were \$3,524, of which 76 percent was from sale of poultry, 17 percent from crop sales, 6 percent from other livestock, and 1 percent from other sources. The average farm and labor incomes on the 20 most profitable farms were \$3,474 and \$2,900, respectively, as compared with —\$165 and —\$648, respectively, for the 20 least productive farms.

Recommendations are made as to size of business, rate of egg production, diversity of enterprises, and efficiency in the use of labor and capital and in marketing.

Succulent feed crops: Cost of producing in northern Wisconsin, E. J. DELWICHE (*Wisconsin Sta. Bul.* 436 (1936), pp. 16, figs. 10).—Trials with corn silage, rutabagas, and sunflower silage were carried on from 1919 to 1935 at the Ashland Substation, and with corn silage and rutabagas from 1919 to 1923 at the Conrath demonstration farm in Rusk County. The average labor costs per ton and per ton of digestible nutrients were for the Ashland Sub-

station (1919-27) sunflowers \$3.95 and \$19.65, rutabagas \$4.22 and \$42.80, and corn silage \$4.69 and \$27.23; at the Conrath farm (1919-23) corn silage \$3.26 and \$19.44 and rutabagas \$2 and \$17.95. Data are also included as to yields and feeding value.

**Economic effects of the corn-hog program in Iowa.** R. H. ROBERTS (*Iowa Jour. Hist. and Politics*, 34 (1936), No. 2, pp. 144-171).—The condition of the corn and hog industry in Iowa as it has developed under the corn-hog programs of 1934 and 1935 is compared with what it would have probably been without such programs.

**The processing tax on wheat.** M. S. KENDRICK (*Amer. Econ. Rev.*, 26 (1936), No. 4, pp. 631-636).—The problems of administration of the processing tax on wheat under the Agricultural Adjustment Act, the yield of the tax, the incidence of the tax, and the effect of the tax on recovery are discussed.

**Crop and livestock insurance: A selected list of references to literature issued since 1898,** compiled by E. M. COLVIN and M. T. OLCOTT (*U. S. Dept. Agr., Bur. Agr. Econ., Agr. Econ. Bibliog.* 67 (1936), pp. VII+264).—This mimeographed bibliography includes 972 annotated references to publications in the United States and foreign countries. "The bibliography is classified under broad subject headings, with references arranged alphabetically under country in each section. There is of necessity a large general section followed by sections dealing with crop, forest fire, frost, hail, and livestock insurance. Under these broad subject headings may be found references to material relating to the history of these different types of insurance; experiments which have been made in the past; plans presented within recent months; legislation, both proposed and actual; and comment and opinion as to the feasibility of such insurance." References relating to the insurance of agricultural labor are omitted, and those dealing with fire insurance relate only to growing crops or to standing timber. References are made to material published in foreign languages only when English summaries could be readily obtained.

**Part-time farming by negroes near Lexington, Kentucky.** M. OYLER, W. W. ROSE, and W. D. NICHOLLS (*Kentucky Sta. Bul.* 365 (1936), pp. 107-121).—This study, similar to the one previously noted for white families (E. S. R., 74, p. 867), was made in cooperation with the Federal and Kentucky Emergency Relief Administrations. Data covering the year ended March 31, 1934, were collected from 104 negroes near Lexington.

The tracts averaged 2.9 acres in size, one-third being  $\frac{1}{4}$  of an acre or less and one-fifth containing  $\frac{1}{2}$  acre. Twenty-six of the tracts were operated by tenants. The work on the tracts averaged 1.8 mo. during the year. The agricultural investment of 60 of the 78 owners was less than \$1,000. The average investment in livestock and machinery was \$22 for tenants and \$37 for owners. The average total income of the operators was \$300, of which 48 percent was from work off the tracts, 14 percent from farm receipts, 16 percent from food furnished from the tracts, and 17 percent was the value of the use of the dwelling. The average earnings per operator were \$81 from the tracts and \$204 from outside income. Three-fifths of the families were young people with few children or retired families whose children had left home.

"The experience of these farmers indicates that many persons who undertake part-time farming with the hope of financial gain are likely to be disappointed. The chance to reduce the cost of living appears to be the chief advantage to be gained by living on a part-time farm. Cheaper food and housing make the part-time farm most attractive to large families with small incomes because such families spend a large share of their income for food and rent; besides, the children can help with the farm work and get recreation in the open country rather than in city streets."

**Regulating the marketing of farm products by State authority.** T. MACKLIN, W. J. KUHRT, and E. L. VEHLOW (*Calif. Dept. Agr. Bul.*, 25 (1936), No. 3, pp. 295-340).—The developments under the provisions of the following 1935 California statutes are presented briefly: Stabilization and Marketing of Fluid Milk and Fluid Cream, California Agricultural Adjustment Act, and California Marketing Agreement Act. The appendix includes the stabilization and marketing plan for fluid milk for the San Francisco marketing area, the marketing agreement regulating the handling of walnuts grown in California, and the marketing agreement for canning asparagus grown and canned within the State.

**Agricultural research projects in marketing which are in progress in the Northeastern States** (*New Hampshire Sta.*, 1936, pp. [8]+28).—This report on projects arranged by the marketing committee of the New England Research Council on Marketing and Food Supply shows as far as possible for each project in progress the title, leaders, date of beginning, probable date of completion, and the principal objectives and comments on the significant findings to date (October 1936).

**Report of the Chief of the Grain Futures Administration, 1936.** J. W. T. DUVEL (*U. S. Dept. Agr., Grain Futures Admin. Rpt.*, 1936, pp. 8).—The act of Congress of June 15, 1936, changing the name of the Grain Futures Act to the Commodity Exchange Act, amending the act in many important respects and extending the provisions to embrace cotton, butter, eggs, potatoes, mill feeds, and rice, and the establishment of the Commodity Exchange Administration are described. Tables show for the year ended June 30, 1936, (1) the volume of trading, extent of commitments, the total actual grain delivered, and related data. The litigation during the year is reviewed.

**Ohio farmer owned elevators: Their financial operations of 1935-36.** B. A. WALLACE (*Ohio State Univ., Dept. Rural Econ. Mimeogr. Bul.* 95 (1936), pp. 18).—This eighth number in the series previously noted (*E. S. R.*, 74, p. 716) is based on the main balance sheets and income and expense items of 189 plants, the detailed analysis of expense items of 45 companies, and commodity sales and margins of 41 companies.

**Cooperative marketing of range livestock.** L. B. MANN (*Farm Credit Admin. [U. S.], Coop. Div., Bul.* 7 (1936), pp. IV+134, figs. 43).—"This bulletin deals principally with the growth and development of cooperative livestock-marketing associations in the western range States." The economic factors affecting production and marketing of range livestock, the characteristics of the western range livestock-producing sections, and the development of cooperative marketing in the range territory and conditions tending to further cooperation are described. The organization set-up, operation methods, and the growth and development of six representative cooperative terminal marketing and three typical direct marketing associations in the range territory are described in more detail. The methods of operation, weaknesses, organization, membership, and operating problems of the two types of associations and cooperative financing of livestock in the range territory are discussed. Analysis is made of the field methods and methods and problems of obtaining and filling orders for feeder stock, the receipts, methods of transportation of cooperatives operating in the western and midwestern markets and of the income and expenses of 13 western and Corn Belt markets. The opportunities for further progress in cooperative marketing in the range territory are discussed. Appendixes include the lamb feeding agreement of the Intermountain Livestock Marketing Association, the marketing agreement of the Producers Livestock Marketing Association of Salt Lake City, and a list showing the name, address, and year of organization of the large scale cooperative livestock-marketing associations in 1935.

**The pooling of lemons, with special reference to the Santa Paula Citrus Fruit Association.**—A progress report, H. R. WELLMAN and M. D. STREET (*California Sta. Mimeogr. Rpt. 55* (1936), pp. 67).—This is a progress report of an analysis of the pooling operations of the Santa Paula Citrus Fruit Association. It is divided into three parts—grade pools, size pools, and time pools. What occurs under each type of pool and the advantages and disadvantages of each type are analyzed and discussed.

**Cooperative purchasing of farm supplies,** J. G. KNAPP and J. H. LISTER (*Farm Credit Admin. [U. S.], Coop. Div., Bul. 1* (1935), pp. IV+92, figs. 15).—The aims and principles of cooperative purchasing of farm supplies, the legal basis, structure, and financing of farmers' cooperative purchasing associations, the methods used in cooperative purchasing, and factors essential to efficient operation of cooperative associations are discussed and suggestions made for guidance in organizing cooperative purchasing associations. The development and present status of cooperative purchasing by farmers in the United States and European and other countries are described. Lists are included of the literature cited, of other selected books and bulletins on cooperative purchasing, and of sources of current information on cooperative purchasing in the United States. Appendixes include (1) a table showing the name, address, and value of farm supplies purchased and farm products marketed by purchasing and marketing associations in each of the 12 Federal Credit Administration districts in the United States; and (2) an article (pp. 88-92) by J. M. Wright on Exemption of Farmers' Cooperative Associations From Certain Federal Taxes.

**A survey of mutualistic communities in America,** R. ALBERTSON (*Iowa Jour. Hist. and Politics, 34* (1936), No. 4, pp. 375-444).—Brief descriptions of a number of communities are included and certain general conclusions drawn.

**Crops and Markets,** [November 1936] (*U. S. Dept. Agr., Crops and Markets, 13* (1936), No. 11, pp. 377-404, figs. 3).—Included are tables, charts, reports, summaries, etc., of the usual types covering crop and livestock estimates, market reports of livestock, livestock, dairy, and poultry products, grains, feeds, seeds, cotton and cold storage holdings, and the price situation of agricultural products.

**The first world agricultural census: Union of South Africa, Commonwealth of Australia, Finland, Argentina, Peru** (*Internat. Inst. Agr. [Roma], First World Agr. Census Buls. 5* (1936), pp. 48; 6 (1936), pp. 67; 9 (1936), pp. 35; 11 (1936), pp. 34; 16 (1936), pp. 11).—These bulletins continue the series previously noted (E. S. R., 74, p. 872). No. 5 presents data for the Union of South Africa, No. 6 for the Commonwealth of Australia, No. 9 for Finland, No. 11 for Argentina (census of livestock), and No. 16 for Peru.

## RURAL SOCIOLOGY

**Factors in the success of rural organizations,** F. BOYD, M. OYLER, and W. D. NICHOLLS (*Kentucky Sta. Bul. 364* (1936), pp. 83-105).—This study, centered around 16 rural organizations selected from the 70 found in 4 representative rural communities in Kentucky, "indicates that training and developing the members and leaders of rural organizations offers the surest method of developing the human resources of rural Kentucky and improving Kentucky agriculture as a way of life."

**The trend of rural relief in ten Ohio counties, June 1 to December 1, 1935,** C. L. FOLSE and C. E. LIVELY (*Ohio State Univ., Dept. Rural Econ. Mimeogr. Bul. 96* (1936), pp. 22, pls. 6).—The object of this report is to show the trend of relief and to describe the changes which occurred in the rural relief population in Ohio from June 1 to December 1, 1935, when the Federal Emergency Relief Administration stopped giving relief.

## AGRICULTURAL AND HOME ECONOMICS EDUCATION

**Organization and costs of Montana schools:** An analysis of the system of financing elementary and secondary education with suggested changes, R. B. BENNE (*Montana Sta. Bul. 335* (1936), pp. 164, figs. 30).—This is an analysis of the present system of financing elementary and secondary education in Montana with suggestions for changes. A summary of the more important findings has been noted (*E. S. R.*, 74, p. 874).

The public school system of the State, school administration, school facilities, enrollment, number, training, and experience of teachers, the sources and size of school receipts, ability of school districts to support schools, size and purpose of school expenditures, the factors determining relative costs in different districts, and the weaknesses of the present system are discussed. A reorganization program is outlined.

"Among the many deficiencies in the present financial and administrative organization of Montana schools are: (1) There are a great number of administrative units (2,116 school districts) and consequently many independent, elective and administrative offices (6,512 school board trustees); (2) The taxing districts vary much in size and wealth and many are too small to provide adequate school support; (3) many schools are operated with extremely low pupil-teacher ratios resulting in high costs per pupil; (4) the financial and accounting procedure is frequently unwieldy and inefficient because of the extreme decentralization of administration; and (5) the financial support of the schools is not stabilized or on a sound and permanent basis because of too large reliance upon local taxes. If these weaknesses are removed in whole or in part, farm taxes would be reduced, the quality of educational services improved, and the administrative efficiency of the schools increased. A reorganization program to correct the above weaknesses must reduce appreciably the present excessive number of administrative units and supplement local district and county taxes with substantial support from State and Federal sources."

## FOODS—HUMAN NUTRITION

**Some factors affecting the cooking quality of the pea and Great Northern types of dry beans,** E. B. SNYDER (*Nebraska Sta. Res. Bul. 85* (1936), pp. 31, fig. 1).—Dry beans of the Great Northern and pea types secured from farms in the western part of the State, including some on sand-hill soil, from two commercial sources in the State, and from experiment stations in Michigan, Colorado, Idaho, and Montana, were studied for factors, either inherent or environmental, which might affect their cooking quality and for modifying procedures.

Each quantity of beans, after being cooked by a uniform method, was sorted by hand into two portions, one of the beans sufficiently soft, and the other of those too hard, for edible use as determined by puncturing each bean by hand with a No. 5 sewing needle. The beans were also judged for edible quality by a special committee.

The important factors determining the cooking quality of the beans studied were found to be the properties of the seed coat and the germinal area of the bean. The initial natural entrance of water into the bean is through the micropyle and germinal regions. The passage of water through the general surface of the seed coat is limited by the structure and composition of the seed coat, which may be hard (1) inherently or (2) as the result of environmental conditions during harvesting and storage or (3) through the effect of chemical solutions such as hard water.

The problem of inherent hardness is suggested to be one for plant breeders to solve by careful selection over a period of years of seeds with permeable

seed coats. The second type of variation in permeability is governed largely by temperature and moisture conditions. Storage in tightly closed containers held at a temperature in the neighborhood of 45° F. was found to be optimum. The third type of variation in permeability is also related to the first, for the nature of the chemicals producing hardness or softness of the seed coat depends upon the composition of the seed coats. Analyses of these showed that they contained relatively large amounts of pectic materials, in the form of pectic acid or pectates, and calcium and small amounts of protein, magnesium, and fatty materials. Beans of the Great Northern type contain about twice as much calcium as the pea beans.

The water absorption of the beans was decreased, and the seed coats were hardened by solutions of hydrochloric and acetic acids in certain concentration and by solutions of sulfates and chlorides of calcium and magnesium. Sulfates and chlorides of sodium and potassium had no deleterious effect, and sodium bicarbonate and ammonium salts of oxalic, citric, and tartaric acids softened the seed coats. It is considered that the use of limited amounts of sodium bicarbonate in practical bean cookery may be justified because of its effect upon the pectic constituents of the seed coats.

Practical bean cooking studies involving customary methods of soaking, parboiling, and cooking in the oven, with or without the addition of various flavoring agents were carried out. Very satisfactory results from the standpoint of flavor and tenderness were obtained when the beans were baked for 4 hr. at a temperature of 350° without preliminary soaking and parboiling. Higher oven temperatures, 400°–450°, produced a satisfactory product in a shorter time, but it was necessary to use a larger amount of water and the beans were crusty. The material of the baking dish, tightness of cover, and temperature of the oven are all factors affecting the amount of water required. The method selected should be determined by the cost of fuel and attention required during the baking.

Factors affecting the cooking qualities of potatoes, M. D. SWEETMAN (*Machine Sta. Bul.* 383 (1936), pp. 297–387, pl. 1, fig. 1).—This bulletin, the purpose of which is "to consider factors causing the variations in potatoes which are of interest to the consumer because they affect value in use, and consequently to the farmer because they affect demand for his product", reviews critically the work of other investigators in the field, and presents the results of the author's studies during a period of 7 yr. In these studies, some of which have been noted from other sources (*E. S. R.*, 66, p. 486; 68, p. 273; 71, p. 559), the author has had the cooperation of D. Folsom and J. Chucka in supervising the securing of the potatoes and of M. W. Dow and M. G. Moore for laboratory assistance.

An introductory section on the appraisal of potatoes from the consumer standpoint closes with the statement that the intelligent selection of potatoes requires primarily a more complete understanding of the factors affecting cooking quality and paring waste. To this end about one-third of the bulletin is devoted to a discussion of the structure of the potato and its composition as affected by various factors and the remaining two-thirds to the properties of potatoes most closely related to their value for culinary use.

The work of the station points to a certain correlation between the percentage of starch or dry matter and mealiness, but with many exceptions to the general rule. The negative correlation between nitrogen content and mealiness is considered to be too irregular to have much significance. In the absence of satisfactory chemical or physical standards for cooking quality, the station recommends buying potatoes by sample and testing the sample under the cooking conditions to be employed in the household as "the most certain method by which the consumer can insure his satisfaction. Storage at temperatures as

high as 50° F. is essential to retain or improve quality found at time of purchase. Inspection at the market may enable one to avoid lots which will give excessive paring waste, but neither appearance nor variety can insure uniform cooking qualities." Other useful hints to the housewife are given as follows:

"Cooking technics influence mealiness, relative high temperatures, and practices which facilitate escape of steam after cooking is complete being favorable. Probably baking and boiling are superior to steaming for highest mealiness. . . . Sloughing can be minimized by cooking bud and stem halves of tubers separately, especially in the fall when bud ends cook more quickly than stem ends. . . . Browning, especially noticeable when frying is the method of cooking, is due to caramelization of sugar and can be controlled indirectly through storage temperatures." Other types of color change on cooking are noted. One of these is caused by the action of iron salts or certain types of hard water on pigment-producing material in the potato. The blackening which may develop on cooking, and especially on standing after cooking, is attributed to an amino acid or other compound which oxidizes to form pigments of the melanin type.

An extensive list of literature references is appended.

**Cake and cake making ingredients**, L. H. BAILEY and J. A. LeCLERC (*Cereal Chem.*, 12 (1935), No. 3, pp. 175-212).—In this contribution from the U. S. D. A. Bureau of Chemistry and Soils, the extensive literature on the subject is reviewed and the results of numerous experimental cake-making studies at the Bureau are summarized.

**A survey of milk consumption in 59 cities in the United States** (*U. S. Dept. Agr., Agr. Adjust. Admin., Consum. Counsel Ser., Pub. 2* (1936), pp. IV+33, figs. 3).—A survey was made of the purchases of whole and evaporated milk by 28,966 representative families in 59 cities during a single week of April or May 1934. Questionnaires were also distributed to 250 selected children in schools located in slum, industrial, and middle-class or well-to-do sections of each city.

The average consumption of whole and evaporated milk amounted to 2.44 qt. per person per week. The highest per capita consumption of whole and evaporated milks per week was reported in the Pacific Division (2.75 qt.), followed in order by the West North Central (2.71), Mountain (2.67), New England (2.66), East North Central (2.38), West South Central (2.33), Middle Atlantic (2.27), East South Central (2.04), and South Atlantic (1.93 qt.).

A definite relationship between milk consumption and income was observed for practically all the cities, the families consuming relatively low amounts of milk being those with small incomes and low expenditures for food, larger number of persons, and children. "The consistent repetition of the relationship suggests that the apparent correlation between size of family and per capita milk consumption is not to be accounted for by race, nationality, or climate."

**Foaming of egg white**, M. I. BAILEY (*Indus. and Engin. Chem.*, 27 (1935), No. 8, pp. 973-976, figs. 5).—The author describes a new method for determining the foaming power of egg white and testing the stability of the foam obtained. No pronounced difference was found in the foaming power of frozen and unfrozen whites other than the tendency of the thawed white to reach a maximum volume in a shorter whipping time and to show greater leakage. If stability of foam is desired, the egg white should not be whipped to its maximum degree of foaming. A greater volume of foam was obtained with thick than with thin whites. With increasing time of whipping, the leakage for the thick whites increased and that of thin whites decreased.

When the pH was varied from 9.5 to 5 by treatment with phosphoric acid the untreated egg white showed a higher foaming power than the treated white, while the foam of the treated egg white adjusted to a pH of 7 or 6 was more stable than the foam of the untreated egg white. If a stable foam is desired, the best results are obtained by prolonged whipping of the egg white adjusted to approximately pH 5. Adding egg yolk decreases the foaming power of the egg white, but to a less extent than when olive oil is added in an amount equivalent to the fat content of the yolk.

[Food studies at the Colorado Station] (*Colorado Sta. Rpt. 1936, pp. 29, 30*).—In continuation of the investigation on baking flour mixtures at high altitudes, progress is reported on a study of the effects of various factors on the characteristics and tensile strength of yellow sponge cake, which is next in simplicity to the previously studied angel food cake (E. S. R., 75, p. 278). Progress is also reported on the study of the culinary quality of potatoes (E. S. R., 75, p. 278).

[Foods and nutrition research of the Texas Station] (*Texas Sta. Rpt. 1935, pp. 124-128, 165, 166*).—Progress reports (E. S. R., 75, p. 131) are given by J. Whitacre on an extension of the analysis of the records of growth in weight and height of Texas school children (E. S. R., 74, p. 877) to show some aspects of the physical status of the three race groups studied, and on a study of the effect of tea upon the energy metabolism of children; by Whitacre, L. R. Hawthorn, and S. H. Yarnell on factors affecting the storage of cucumbers; by S. Cover and H. Schmidt on the effect of oven temperature on the tenderness of meat and on the processing of canned meat; and by H. M. Reed on a continuation of fig products investigations.

Food and Drugs Act, W. G. CAMPBELL (*U. S. Dept. Agr., Food and Drug Admn. Rpt., 1936, pp. 1-19*).—This annual report on the enforcement of the Federal Food and Drugs Act (E. S. R., 74, p. 721) contains summaries of the food adulterations investigated involving public health, filth and decomposition, and economic cheats; of the seizures of canned fruits and vegetables under the McNary-Mapes amendment; of the inspection of the shrimp-canning industry under the sea-food amendment; and of the inspection and seizure of chemicals and medicinal preparations reported as complying with the standards of the United States Pharmacopoeia and National Formulary or sold under their own standards of strength, and of proprietary medicines, anesthetic ether, and rubbing alcohol. Progress reports are also given of the work of the Vitamin Division and the Division of Pharmacology, of the development of new analytical methods and apparatus, and comments on court cases.

The newer ideas in health inspection, F. W. FABIAN (*Fruit Prod. Jour. and Amer. Vinegar Indus., 15 (1936), No. 10, pp. 295, 313*).—This general discussion closes with the recommendation that every employee in the food and dairy industry be required to take a complete medical examination by a competent physician, with laboratory examination of blood, feces, and urine at the time he is employed and semiannually thereafter, and that in addition as an added protection all employees coming in direct contact with food, milk, or dairy products be examined daily by a nurse, foreman, or some other person for evidence of contagious diseases. It is also suggested that "only people who are inherently clean should be employed in the food or dairy industry. All new employees should be watched carefully until they have been so classified."

Height, weight, and age tables for homogeneous groups, with particular reference to Navaho Indians and Dutch whites, M. STEGGERDA and P. DENSEN (*Child Develpmt., 7 (1936), No. 2, pp. 115-120, figs. 2*).—Because of the desirability of height and weight tables specifically for homogeneous groups, tables

have been prepared for 3,332 Navaho Indian children from 6 to 18 yr. of age and 3,730 Dutch white children from 6 to 15 yr. of age.

**A nutrition study of a Slavic agricultural family according to a record of the food consumption for one year** [trans. title], H. PELC and M. PODZIMKOVÁ-RIEGLOVÁ (*Trav. Inst. Hyg. Pub. Tchécoslov.*, 5 (1934), No. 4, pp. 129-162, figs. 42).—Using the individual method, food consumption details were recorded for a family consisting of the grandmother, mother, father, and two small children.

Curves show a minimum food consumption during the winter, a definite ascent to spring, and the largest consumption in the summer. The selection of foods was made almost entirely from those foods produced on the farm, so that milk was the principal food and very little meat was eaten. The menus appear monotonous, but the authors conclude that if this is a typical example, the farm families in this district of central Czechoslovakia are receiving adequate diets.

**Plotting of a graphic record of growth for children aged from one to nineteen years**, L. M. BAYER and H. GRAY (*Amer. Jour. Diseases Children*, 50 (1935), No. 6, pp. 1408-1417, figs. 6).—In the method described the charts are planned on the expectancy that the stature of 96 percent of normal boys and girls will fall within 8 percent above or below the average height for the age, and the weight within  $\pm 20$  percent for boys and  $\pm 24$  percent for girls. The graphs provide a simple visual record of a child's growth, shown by a progressive process related to the individual developmental tendency of the child, as well as to the normal value.

**Maintenance nutrition in the pigeon.**—The influence of dietary protein and vitamin B<sub>1</sub>, C. W. CARTER and J. R. O'BRIEN (*Biochem. Jour.*, 29 (1935), No. 12, pp. 2746-2754, fig. 1).—In this contribution to the question as to the nature of the multiple deficiencies in an exclusive diet of polished rice responsible for the syndrome of human beriberi and avian polyneuritis, a series of feeding experiments with pigeons is reported, leading to the following conclusions:

Limitation of protein rather than total caloric intake is one of the factors which prevent full weight recovery in pigeons on polished rice supplemented solely by a vitamin B<sub>1</sub> preparation, but the evidence thus far does not differentiate between limitation of protein per se and a deficiency of some specific amino acid. The response to an adequately adjusted protein intake is only partial or may be absent entirely if the preliminary period of depletion on polished rice results in a fall of weight below 70 per cent of the maximum. "In such cases recovery is limited by the appearance of a deficiency of vitamin B<sub>1</sub>, which is wholly or largely lacking in the diet. This deficiency can be corrected by the administration of vitamin B<sub>1</sub> in the form of extracts of liver. Our experiments, therefore, seem to indicate that two factors at least are necessary to promote weight restoration in pigeons on polished rice supplemented with vitamin B<sub>1</sub>: (1) Protein in adequate amount and (2) vitamin B<sub>1</sub>."

**The influence of nutrition on the production of ulcers in the pro-stomach of the rat**, P. ABONS and M. P. J. VAN DER RIJST (*Arch. Néerland. Physiol. Homme et Anim.*, 21 (1936), No. 2, pp. 274-282, fig. 1).—Observations are reported on the extent of stomach ulcer formation in groups of rats fed various deficient diets. Although the proportion developing ulcers on a vitamin A-free diet was higher than on the other deficient diets, ulcers were also found in some rats on a diet deficient in vitamins B<sub>1</sub> and the B complex, on diets qualitatively complete but fed in limited amounts, and in starvation.

**Blood plasma protein regeneration controlled by diet.**—Effects of plant proteins compared with animal proteins. The influence of fasting and infection, J. B. McNAUGHT, V. C. SCOTT, F. M. WOODS, and G. H. WHIFFLE (*Jour. Expt. Med.*, 63 (1936), No. 2, pp. 277-301).—The general plan of the

studies reported was similar to that employed by Whipple and associates in long-continued investigation of factors promoting hemoglobin regeneration in dogs rendered anemic by repeated bleedings. In the present investigation the plasma proteins of dogs were depleted by the removal of whole blood and the return of normal red cells suspended in Locke's solution. This process was repeated daily until the plasma protein levels were reduced from normal (5-7 percent) to about 4 percent. The substances to be tested were then added to the basal diet and the plasmapheresis continued at definite intervals. From analyses of the blood samples the potency ratios of the supplemental feedings were determined, these being the number of grams of protein which had to be fed to regenerate 1 g of plasma protein in a depleted standard dog.

The plant proteins tested were quite well utilized to form new plasma protein, with soybean meal rated at the head of the list. "It is utilized with unexpected promptness and favors the production of albumin in contrast to other plant proteins which distinctly favor globulin production." In two experiments with soybean meal the potency ratios were 4.6+ and 7.1. Other values reported were bran 4.3, rice polishings 5.3, potatoes 6.1, liver 6.4, spleen 10.2, brain 11.8, and stomach 13.6.

Long plasmapheresis periods on basal rations rich in grain proteins were found to lower the resistance of the animals to infection. In fasting only from 4 to 6 g of plasma protein per week were formed.

**Fat and calcium metabolism.**—III, The influence of butter and margarine upon the fecal output of Ca in full-grown rats, A. WESTERLUND (*Lantbr. Högsk. Ann. [Uppsala]*, 2 (1935), pp. 51-70, fig. 1; *Swed. abs.*, pp. 67-69).—In continuation of previous studies (E. S. R., 73, p. 127), the object of this investigation was to compare the effect of butter and margarine on the calcium metabolism of albino rats. Eight male rats were subjected to at least one margarine and one butter experiment. The food mixtures were uniform in energy value, 11 containing margarine and 9 butter, the quality and quantity of the fat being the only variable factors.

The calcium eliminated in the intestine was much greater in the margarine group, but no significant difference could be found regarding urinary calcium elimination. The author concludes that with a moderate calcium consumption the body loses much more calcium when the fat in the diet is margarine than when it is butter. No definite reason for this is given, but it is suggested that the vitamin D content of the butter may be a factor or that the greater concentration of fatty acids in the margarine may affect the calcium metabolism.

**Experimental sodium chloride deficiency in man**, R. A. McCANCE (*Roy. Soc. [London], Proc., Ser. B.*, 119 (1936), No. 814, pp. 245-268, fig. 1).—This is the report of a study of severe uncomplicated salt deficiency in one woman and two men, all in good health when the experiment began. The diet consisted of salt-free "casein" bread, synthetic salt-free milk, salt-free butter, fruit, thrice boiled vegetables, jam, home-made salt-free shortbread, and toffee. Water was taken as desired. A forced loss of sodium and chlorine was produced by the very low salt intake and by sweating under controlled conditions.

The low salt content of the body—about 25-30 percent of the body's extracellular ions were removed—caused evident signs of debility, loss of the ability to taste, cramps, weakness, lassitude, and, upon any degree of exertion, cardio-respiratory distress. The tests showed a negative nitrogen balance, an increase in the blood urea, a reduction of blood volume, and a rise in hemoglobin, protein, and colloid phosphorus in the serum. There was a reduction of the concentration of sodium and chlorine in the serum, with a fall in its total osmotic pressure.

**The determination of vitamin A by means of its influence on the vaginal contents of the rat**, K. H. COWARD, M. R. CAMDEN, and E. M. LEE (*Biochem.*

*Jour.*, 29 (1935), No. 12, pp. 2736-2741, figs. 3).—The method described is based upon the vaginal smear method of detecting vitamin A deficiency as first reported by Evans and Bishop (*E. S. R.*, 50, p. 163) and later confirmed by Baumann and Steenbock (*E. S. R.*, 69, p. 630) and others.

Female rats which had grown to about 130 g in weight on a diet of moderate vitamin A content were examined by the vaginal smear method until it was determined that the cycles were occurring regularly and were then placed on a vitamin A-free diet until keratinized cells appeared in the vagina for 10 successive days. One dose only of the vitamin A-containing substance to be tested was then given, and the length of time before the disappearance of cornified cells was determined by daily smear tests.

When single doses of 5, 10, 20, 40, 60, 100, and 200 mg of cod-liver oil were given to groups of rats thus prepared and the mean number of days elapsing between the administration of the dose and the disappearance of cornified cells was plotted against the respective dosage, the curve was logarithmic in shape. When the duration of the cure in days was plotted against the respective single dosage of cod-liver oil, the curve which resulted was not logarithmic.

The probable error in this method of estimation in the results obtained with 10 rats was +36.2 or -26.4 percent, which was slightly greater than that obtained in a 3 weeks' growth test on young female rats which had been given daily doses of vitamin A after they had ceased to grow on a diet deficient in that factor.

The effect of vitamin A deficiency on the development of the retina and on the first appearance of visual purple, K. TANSLEY (*Biochem. Jour.*, 50 (1936), No. 5, pp. 839-844).—Attempts were made to obtain rats deficient in vitamin A during the first 3 weeks of life in order to determine whether such a deficiency would result in abnormalities in the rod structure of the developing retina as well as in the formation of visual purple.

Only a moderate deficiency of vitamin A in rats during the suckling period could be induced, for too severe a deficiency during pregnancy led to a prolonged gestation period, abnormal and difficult labor, and failure to suckle the young. In young rats suffering from a mild deficiency of vitamin A the development of visual purple was retarded and in some cases prevented, but the effect on the structure and development of the rods was not so marked. This is thought to indicate that the first effect of vitamin A deficiency on the developing retina is on the visual purple formation, with damage to the rod structure as a later effect.

Further study of the growth effect of the residue remaining after alcoholic extraction of yeast, M. R. RYMER and R. C. LEWIS (*Jour. Biol. Chem.*, 114 (1936), No. 2, pp. 361-367).—In a further study of the alleged third factor reported by Williams and Lewis (*E. S. R.*, 65, p. 94) to be present in the yeast after prolonged alcoholic extraction, a similar experimental procedure was followed to that reported earlier, using five different preparations as the vitamin supplements. These were unfractionated yeast extract and the yeast residue described by Williams and Lewis, a rice polishings concentrate relatively rich in vitamin B and poor in vitamin G made according to the method of Evans and Lepkovsky (*E. S. R.*, 65, p. 613), and two preparations rich in vitamin G and poor in vitamin B. One of these was dried autoclaved liver prepared according to the method of Graham and Griffith (*E. S. R.*, 69, p. 899) and the other egg white concentrate prepared according to the method of Chick, Copping, and Roscoe (*E. S. R.*, 65, p. 591).

The addition of each of these preparations except the yeast residue to the diet on which the deficiency had been demonstrated resulted in increased growth which was not stimulated further by the addition of the yeast residue.

Although admitting that the previously demonstrated growth-promoting ability of the yeast residue must be due in large measure to the presence of vitamins B and G, the authors state that they "do not feel justified in drawing the unqualified conclusion that the yeast residue contains no other growth factors than those of vitamin B and vitamin G. We are working with very complex, impure substances, and it must be borne in mind that the liver, rice polishings concentrate, or yeast extract may have contained the same 'third factor' that was postulated for the yeast residue. The final solution of the problem of whether a third factor actually exists lies in the use of preparations of vitamins B and G which are free from traces of other factors."

**Effects of vitamin B on the blood count and hemoglobin content of normal albino rats, R. SUMNER** (*Colo. Univ. Studies*, 23 (1936), No. 4, pp. 315-320 fig. 1).—This is an investigation of the effect of whole vitamin B and crystalline vitamin B<sub>1</sub> on the blood counts of rats receiving a normal diet. Thirty-four albino rats from 57 to 68 days old were divided according to sex into two control and two experimental groups. The control diet consisted of 10 ml of a mixture consisting of 1 packed level tablespoonful of powdered milk with 60 ml of water, a half leaf of lettuce, and 1 heaping teaspoonful of boiled wheat. Five drops of cod-liver oil were administered every other day. The experimental groups were fed whole vitamin B in the form of 12 mg of powdered yeast in milk every day as a supplement to the control diet. The genetic factor was controlled.

One male rat about 9 mo. old and of unknown genetic background was also given crystalline vitamin B<sub>1</sub> in the amount of 1 mg daily for 5 days, alternating with 5-day periods without the vitamin.

The rats receiving whole vitamin B showed an increased erythrocyte count and a decrease in the hemoglobin percentage, leucocyte, and blood platelet counts from those of the control rats. During the days the crystalline vitamin B<sub>1</sub> was fed, the one rat noted above showed a significant decrease in the erythrocyte count, a slight rise in percentage of hemoglobin, and increased leucocyte and blood platelet counts. A comparison of the results shown by the one rat of unknown genetic background with those of the groups of rats of known strain indicated that the effects on the blood constituents produced by the whole vitamin B are not due to the B<sub>1</sub> factor.

**Further evidence for the existence of vitamin B<sub>4</sub>, O. L. KLINE, C. A. ELVEHJEM, and E. B. HART** (*Biochem. Jour.*, 30 (1936), No. 5, pp. 780-784, figs., 2).—In this contribution from the Wisconsin Experiment Station further experimental evidence confirming the earlier observations of Reader (E. S. R., 64, p. 195) is presented for the existence of vitamin B<sub>4</sub> and its necessity in the normal nutrition of the rat. It is shown that success in producing vitamin B<sub>4</sub> deficiency in the rat depends to a very large extent upon the purification of the various constituents of the diet.

In the experiments reported the diet (44<sub>2A</sub>) was designed after that used in the chick experiments noted on page 515, but more highly purified. The dextrin was heated for 24 hr. at 120° C., and the casein, prepared from skim milk, was purified by reprecipitation from dilute ammonium hydroxide solution with dilute hydrochloric acid at pH 4.6 and washing with distilled water, the treatment being repeated three times. The vitamin supplements other than B<sub>4</sub> included two crystalline vitamin B<sub>1</sub> preparations, a commercial water-extracted liver residue autoclaved 10 hr. at 120° to destroy any residual B<sub>4</sub> and a vitamin B<sub>4</sub> concentrate prepared according to the method of Elvehjem and Koehn (E. S. R., 74, p. 885).

The technic for producing the deficiency was that of Reader (E. S. R., 65, p. 594). In a subsequent experiment the vitamin B<sub>1</sub> concentrate was replaced by crude liver extract powder which had been aerated in water solution at 100° for 24 hr. to destroy vitamin B<sub>1</sub>. The Reader technic of first producing polyneuritis in the rats was found unnecessary, and from the tenth day suckling rats were given the diet (44<sub>2H</sub>) supplemented with 0.5γ of vitamin B<sub>1</sub> per gram of diet. From the twenty-fifth day the rats received 5γ of vitamin B<sub>1</sub> daily by dropper.

The rats showing symptoms of vitamin B<sub>1</sub> deficiency were inactive, sat in an extremely hunched position, and when walking retained the characteristic humped back, "walking high" on the hind legs, and as the condition developed, noticeably lost coordination. The diets were supplemented when the growth rate declined and when symptoms of vitamin B<sub>1</sub> deficiency appeared. Rats on the basal diet 44<sub>2H</sub> gained 25 g in weight in a 5-week period. When the diet was supplemented with vitamin B<sub>1</sub> concentrate (E. S. R., 68, p. 726) the gain was 139 g, and when 10 percent of peanuts was included in the diet the gain was 105 g. These supplements also completely cured the paralytic symptoms.

**Vitamin B<sub>1</sub> deficiency in the rat's brain**, J. R. O'BRIEN and R. A. PETERS (*Jour. Physiol.*, 85 (1935), No. 4, pp. 454-463).—In continuation of studies on tissue respiration and metabolism during vitamin B<sub>1</sub> deficiency (E. S. R., 75, p. 285), data were obtained on the respiration in vitro of teased brain tissue of normal and neuritic rats. In avitaminous brains in vitro the oxygen uptake was increased by the addition of vitamin B<sub>1</sub>, and abnormal amounts of pyruvate were reduced. The effects of the addition of vitamin B<sub>1</sub> were negligible with the normal brain. The observations on oxygen uptake indicated that the symptoms of vitamin B<sub>1</sub> deficiency in the rat and pigeon originated in the optic lobes and the lower parts of the brain. The symptoms had the same biochemical origin.

**The biochemical lesion in vitamin B<sub>1</sub> deficiency: Application of modern biochemical analysis in its diagnosis**, R. A. PETERS (*Lancet [London]*, 1936, I, No. 21, pp. 1161-1164, 1165, figs. 2).—The author presents a review of the in vitro experiments with vitamin B<sub>1</sub>, demonstrating that vitamin B<sub>1</sub> appears to act as a catalyst in the oxidative removal of one of the lower degradation products of carbohydrate metabolism, pyruvic acid. This view is substantiated by experiments showing the presence of pyruvic acid in the brains of avitaminous birds and in the blood of beriberi patients. In improving the pigeon test for vitamin B<sub>1</sub>, the author found that the addition of minute amounts of crystalline vitamin B<sub>1</sub> in vitro to the avitaminous brain tissue of the bird restored the diminished tissue respiration. The ability of vitamin B<sub>1</sub> to increase oxygen uptake can be used as a test for the estimation of the vitamin, and in vitro research upon brain tissue may be applied in vivo.

Most of the evidence reviewed has been noted above.

**Observations on the heart rate in vitamin B<sub>1</sub> and C deficiency**, G. SANKARAN and B. G. KRISHNAN (*Indian Jour. Med. Res.*, 23 (1936), No. 3, pp. 747-754, figs. 2).—The bradycardia test for vitamin B<sub>1</sub> deficiency, first noted by Drury et al. and later used by Birch and Harris (E. S. R., 73, p. 567) in estimating the vitamin B<sub>1</sub> content of foodstuffs with rats as the experimental animal, was studied with both pigeons and rats, with results confirming those of the above-noted investigators. Similar heart tests applied to guinea pigs on a vitamin C-free ration showed a marked increase in heart rate, or tachycardia, beginning at about the ninth week.

**Factors affecting the vitamin C content of apples**, E. L. BATCHELDER and E. I. OVERHOLSER (*Jour. Agr. Res. [U. S.]*, 53 (1936), No. 7, pp. 547-551).—In

this contribution from the Washington Experiment Station, Delicious apples grown on unringed branches and Winesap apples grown on ringed branches were adjusted early in July to approximate leaf-fruit ratios of 60 and 20 leaves to each fruit. After harvesting the apples were stored at 32°. As in a previous study (E. S. R., 73, p. 136), a modification of the Sherman, LaMer, and Campbell method of determining vitamin C was followed.

It was concluded that the ratio of leaf area to fruit affected the vitamin C content of apples only indirectly, i. e., as it affected the size of the fruit produced; that the size of the fruit was an important consideration under common methods of sampling because the ratio of skin to pulp was higher in small apples than in large apples, and the skin contained a higher concentration of vitamin C than the pulp; that storage at 40° resulted in greater loss of vitamin C than did storage at 32°; and that the vitamin C content of Delicious apples in the present study corresponded closely with values hitherto reported from this laboratory.

The excretion of vitamin C in normal individuals following a comparable quantitative administration in the form of orange juice, cevitamic acid by mouth, and cevitamic acid intravenously, E. E. HAWLEY, D. J. STEPHENS, and G. ANDERSON (*Jour. Nutr.*, 11 (1936), No. 2, pp. 135-145, figs. 4).—The variations of vitamin C excretions of 12 normal young adults were studied by the Harris and Ray technic (E. S. R., 73, p. 427) during periods of low and high vitamin C intake. For a period of 1 week the subjects were given a diet free from fresh vegetables, fruits, tomatoes, and tomato juice, reducing the vitamin C intake to 10-20 mg per 24 hr. For the second period of 8 days the diet was supplemented by 400 cc of orange juice estimated to have 50-60 mg of cevitamic acid per 100 cc. In the third period the orange juice was reduced to 200 cc, with the addition at the end of the period of 100 mg of cevitamic acid given first orally and then injected intravenously. Before concluding the study the subjects were put on a vitamin C-free diet for 2 days, followed by additions of 400-1,000 cc of orange juice. Four figures are given in which the daily intakes in 24-hr. excretions of cevitamic acid are plotted.

The amount of vitamin C normally excreted by individuals varied between 15 and 28 mg per 24 hr. It was increased to comparable levels by daily additions of orange juice and cevitamic acid given orally. The injected cevitamic acid was excreted more rapidly and completely than that given by mouth. Individuals varied in their response to increased doses of vitamin C. No change was noted in the cevitamic acid content of blood or capillary fragility during the low and high vitamin periods.

Effect of ingestion of acid and alkali upon amount of vitamin C found in urine, E. E. HAWLEY, J. FRAZER, L. BUTTON, and D. J. STEPHENS (*Soc. Expt. Biol. and Med. Proc.*, 34 (1936), No. 2, pp. 218, 219).—Unexplainable variations in the vitamin C output of several individuals in the study noted above suggested the possibility that changes in the pH of the urine might be responsible for the difference in results. In preliminary tests marked changes in the vitamin C content of the urine of a subject were found to be correlated inversely with the pH values. To test this further, 3 subjects at first and later 2 were on a constant diet with the pH varied by the ingestion of  $\text{NaHCO}_3$  or  $\text{NH}_4\text{Cl}$ , with frequent determinations of the vitamin C of the urine after its administration as orange juice and as cevitamic acid by mouth and by intravenous injection.

A marked decrease in output resulted in all cases when the urinary pH was in the alkaline range of 7.5-8.1. The effect was found not to be due to a reversible oxidation. It is thought more likely that it was due to better utilization (increased storage) of the vitamin rather than its destruction.

**The effect of incomplete diets on the concentration of ascorbic acid in the organs of the rat, S. S. ZILVA** (*Biochem. Jour.*, 30 (1936), No. 5, pp. 857-867).—This paper reports a repetition of the studies by Hopkins and Slater (*E. S. R.*, 76, p. 184) leading to the hypothesis that the liver is the ordinary site of vitamin C synthesis, but that in the absence of carbohydrate in the liver the intestine is capable of synthesizing the vitamin from some other precursor, probably protein.

Some of the major results reported by Hopkins and Slater could not be reproduced, while others were differently interpreted. The author, therefore, concludes that "Hopkins's hypothesis, attractive as it may be, is so far not fully supported by experimental evidence."

**The relation between the composition of the diet and the urinary excretion of ascorbic acid, R. K. CHAKRABORTY and A. N. ROY** (*Indian Jour. Med. Res.*, 23 (1936), No. 3, pp. 831-836).—The excretion of ascorbic acid in the urine on diets differing in the proportions of fat and protein was followed with two healthy Bengali males.

In one of the subjects the average daily urinary output of ascorbic acid on the usual Bengali high carbohydrate diet was 9.54 mg. This rose to 12.07 mg on a high protein (meat diet), fell to 10.21 mg on resumption of the high carbohydrate diet, rose again to 14.09 mg on a high fat (butter) diet, fell to 9.57 mg on resumption of the high carbohydrate diet, and rose to 14.65 mg on another high protein (casein) diet. Corresponding values for the second subject were high carbohydrate 9.75 mg, high protein (meat) 11.08, high carbohydrate 8.51, high fat 14.8, high carbohydrate 10.40, and high protein (casein) 13.12 mg.

It is suggested that the higher figures for urinary excretion of ascorbic acid in England, as reported by Harris and Ray (*E. S. R.*, 73, p. 427), are due to a greater consumption of meat in that country. It is also noted that the relatively low figures reported in the present study do not necessarily indicate vitamin C subnutrition, as in some unpublished experiments a sharp peak in urinary excretion followed the ingestion of extra vitamin C.

**Vitamin C in the urine in health and disease** [trans. title], W. v. DRIGALSKI (*Klin. Wchnschr.*, 14 (1935), No. 10, pp. 338, 339).—This paper reports an investigation of the effect of age and disease upon the daily amounts of vitamin C excreted in the urine as determined by the method of Harris and Ray (*E. S. R.*, 73, p. 427). The values obtained were about 50 percent higher and showed greater variation than those reported by Harris and Ray, indicating a lower amount of vitamin C in the diet of the English persons.

The average daily excretion of ascorbic acid of healthy adults amounted to 37-79 mg, or an average of 50 mg per 100 cc. The highest amounts noted were 100 and 114 mg. Age and sex, except for the nursing mother, had no marked effect upon the amounts excreted. Diets rich in vitamin C increased the vitamin excretion. Nursing infants excreted an average daily amount of 16 mg, which with the addition of fruit juices at 4 mo. increased to 22 mg. Children 5 mo. to 1 yr. excreted an average of 24 mg, and children aged 3-10 yr., 25-30 mg daily.

In 51 cases persons afflicted with a disease showed no variation from the normal in the amounts of vitamin C in the urine. In general the diseases were those which affect the functions of HCl, the stomach, liver, and kidneys; metabolism as in diabetes, exophthalmic goiter, and disturbances of endocrine glands; and those accompanied either by high fever or fever for long periods of time.

The vitamin C excretion was not altered by exposure to the sun or by diets rich in vitamins A, B, and D, or by the types of diets customarily fed to

diabetic, nephritic, and ulcer patients. Large amounts of liquids caused an increased elimination of the vitamin. However, the amounts excreted did not show a definite relation to the amount of urine, but showed a limitation in the amount similar to other constituents of the urine. The highest concentration was 10.4 percent. Increased ingestion of vitamin C in the presence of a disease resulted in increased excretion in the urine.

The nursing mother excreted about half the amount of vitamin C excreted by the man when both partook of the same foodstuffs. The nursing child excreted approximately the other half of the total amount.

**Vitamin C in the urine in health and disease** [trans. title], E. GABBE (*Klin. Wehnschr.*, 14 (1935), No. 17, p. 613).—The author states that the above noted observations of Drigalski on the excretion of vitamin C in the urine are unwarranted, since other substances, particularly thionine which is present in large quantities in the urine, similarly reduce the dye giving vitamin C values approximately 30 percent above absolute amounts.

**Vitamin C in the urine in health and disease** [trans. title], W. v. DRIGALSKI (*Klin. Wehnschr.*, 14 (1935), No. 17, p. 614).—In reply to the criticism of Gabbe, as noted above, the author states that while the method used to determine vitamin C by the reducing action of ascorbic acid and certain other substances in the urine is not specifically accurate, it cannot be denied that the method is useful for obtaining comparative values.

**Vitamin C studies in urine and blood** [trans. title], E. GABBE (*Klin. Wehnschr.*, 15 (1936), No. 9, pp. 292-296, figs. 2).—The purpose of this study was to determine the forms in which vitamin C is present in the blood and urine, the effect of oxidizing substances on the stability of the reduced form of ascorbic acid, and the effect of increased intake on the stability of the reduced form. The determinations on these fluids were made with the iodine reduction method and the methylene blue method described by Martini and Bonsignore (*E. S. R.*, 73, p. 746) before and after treatment with hydrogen sulfide.

To determine the presence of an oxidizing substance in urine, blood plasma, and deproteinized blood, 100 mg percent ascorbic acid was added in vitro to the fluid. This was then neutralized with sodium hydroxide solution and allowed to stand for 5 min., after which it was treated with trichloroacetic acid, titrated with methylene blue and iodine solutions, and the loss in ascorbic acid through oxidation calculated. To determine the oxidized form of ascorbic acid the same procedure was followed but with distilled water in place of blood and calculating the difference in the values obtained by the two determinations.

The ascorbic acid was found to occur in the urine in the reduced, reversibly oxidized, and oxidized forms. The methylene blue values showed that a healthy person on a normal diet excreted daily from 16 to 35 mg of ascorbic acid, of which from 16 to 90 percent was present in the reduced form. The iodine values were regularly from 4 to 5 times higher than the values obtained with methylene blue solutions. Treatment with hydrogen sulfide to reduce the reversibly oxidized form of ascorbic acid increased the values obtained by both methods, but notably from 2 to 3 times more with the iodine reduction method. An addition of 250 mg of ascorbic acid to the diet of a healthy person increased the amount of ascorbic acid excreted in the urine from 40 to 48 mg determined with the methylene blue method and from 210 to 235 mg determined with the iodine method after treatment with hydrogen sulfide. The loss of ascorbic acid in the urine in vitro, from 10 to 12 mg of ascorbic acid determined with the methylene blue method and from 10 to 20 mg determined with the iodine method, indicated the presence of an oxidizing substance in the urine. While blood plasma in vitro caused no oxidation of added ascorbic

acid, blood corpuscles as shown with deproteinized blood always contained oxidizing substances. The daily addition of 300 mg of ascorbic acid to the diet of 3 patients increased the amount of ascorbic acid in the urine, but decreased the amount of the oxidized form in the blood and urine. This decrease was thought to be due to a reduced oxidizing power of the fluids. Parallel to the reduction of oxidized ascorbic acid was a reduction of glutathione in the blood of 2 patients but not in that of the third. When glutathione free from ascorbic acid was added to the hemolyzed blood an increased oxidation of ascorbic acid took place. A substance protecting ascorbic acid against oxidation in the body was indicated, but its nature was not revealed by this study.

**The antirachitic effectiveness of vitamin D from various sources, R. W. HAMAN and H. STEENBOCK** (*Jour. Biol. Chem.*, 114 (1936), No. 2, pp. 505-514, fig. 1).—This contribution from the Wisconsin Experiment Station reports several series of experiments undertaken with the general aim of determining "how many forms of vitamin D must be recognized, to what extent each occurs in nature or is produced artificially by irradiation, what factors influence the activity of each, and how each may be evaluated properly by laboratory assays with animals."

In the first series the relative effectiveness for rats and chicks of irradiated oils of plant and animal origin was determined. In the work with rats it was shown that irradiation of the fish oils tested failed to increase their vitamin D activity, while corresponding irradiation of plant oils increased this activity to a varying extent. It required from 15 mg of irradiated coconut oil to 750 mg of irradiated soybean oil and lard to give an antirachitic activity equivalent to 1 Steenbock (rat) unit or 3.3 international units of vitamin D.

The vitamin D activity of cod-liver oil for chicks was not increased by irradiation, and the effectiveness of the vitamin D in various fish oils was approximately the same for the chick as for the rat. Commercial tuna-liver oil and pure halibut-liver oil were somewhat less effective, unit for unit, than the other oils tested. The vitamin D in irradiated coconut oil, wheat germ oil, and peanut oil was much less potent for chicks than for rats.

In another series of experiments it was shown that propylene glycol as a solvent for vitamin D did not increase its effectiveness, that the solvent in which ergosterol or cholesterol was dissolved during irradiation had no effect on the relative antirachitic effectiveness for chicks of the resultant D vitamins, and that purified cholesterol heated and then irradiated produced a response in chicks more like that produced by irradiated crude cholesterol than irradiated ergosterol. Absorption bands could be detected in the spectrum of heated purified cholesterol.

**Vitamin D in child health, F. O. TONNEY** (*Amer. Jour. Pub. Health*, 26 (1936), No. 7, pp. 665-671, figs. 2).—The purpose of this paper is to review the recent experimental data on vitamin D in child health from the standpoint of growth, bone development, tooth development, posture, and resistance to infection.

The evidence of rickets in cities is far higher than that for any of the common infections of childhood, such as measles, scarlet fever, whooping cough, and diphtheria. On the basis of recent surveys, rickets is conceded to be present in at least 50 percent of the child population under 2 yr. of age. Recent progress with antirachitic agents advocated for the cure or prevention of rickets cannot be demonstrated, but definite results are evidenced from the fact that the incidence of rickets is receding both in severity and number of cases. The potential usefulness of vitamin D milk as an antirachitic agent cannot as yet be judged. A table showing the sale of vitamin D milk as compared with the total sale of milk in Chicago from June 1934 to June 1935 is given.

**A theory concerning the mechanism and the significance of the allergic response,** W. T. VAUGHAN (*Jour. Lab. and Clin. Med.*, 21 (1936), No. 6, pp. 629-649).—The purpose of this paper is to demonstrate the basic identity of clinical allergy as seen in human beings and experimental anaphylaxis as seen in animals. A theory is presented that the allergic response is primarily a protective reaction manifested by environmental maladjustment. The two factors appear to be heredity and the nature of the exciting substance. There appear to be all grades of response to exciting factors. For the alleviation of symptoms the author suggests either avoidance of environment, or, if that is not possible, desensitization. The hypothesis suggests two lines of experimental approach—through the endocrine system, especially the adrenals, and the autonomic nervous system. It is possible that neither system is responsible for the mechanism.

**The action of choline and other substances in the prevention and cure of fatty livers,** C. H. BFST and H. J. CHANNON (*Biochem. Jour.*, 29 (1935), No. 12, pp. 2651-2658).—A detailed review is given of studies at the Liverpool (E. S. R., 76, p. 128) and the Toronto (E. S. R., 74, p. 280) laboratories on the action of choline and other substances in the prevention and cure of dietary fatty livers. The differences in the results reported from the two laboratories are shown to be "not at qualitative variance but to differ only in degree, governed by the somewhat different conditions under which experiments have been carried out."

The precautions necessary for planning diets adequate for observing the effects of choline are discussed, and new data obtained at the Liverpool laboratory on the preventive action of choline on the "fat" and "cholesterol" fatty livers, confirming findings previously obtained at the Toronto laboratory, are reported.

**The influence of the caseinogen content of diets on the nature of the "cholesterol" fatty liver,** A. W. BEESTON, H. J. CHANNON, and H. WILKINSON (*Biochem. Jour.*, 29 (1935), No. 12, pp. 2659-2667).—Further data are reported which confirm the results of Channon and Wilkinson (E. S. R., 76, p. 129), in showing that "in the cholesterol fatty liver the dietary protein fraction exercises a profound lipotropic effect. By the use of graded protein percentages in the diet it is thus possible to produce cholesterol fatty livers of widely varying composition, and these findings have been used in further experiments for studying the preventive effects of choline. These experiments have shown that the addition of approximately 80 mg of choline per rat per day very largely prevents the deposition of glyceride, but only partially prevents that of cholesteryl esters. No deductions could be made from the experiments as to whether choline is exerting its effect through lecithin synthesis or whether choline has a direct action in preventing cholesteryl ester deposition. The lipotropic effect of the protein fraction differs superficially at least from that of choline in that the absolute amount of liver phosphatide is increased."

**Cystine and the dietary production of fatty livers,** A. W. BEESTON and H. J. CHANNON (*Biochem. Jour.*, 30 (1936), No. 2, pp. 280-284).—In this continuation of the studies noted above, groups of rats were maintained on a low choline diet containing 40 percent beef drippings and 5 percent casein supplemented with amounts of cystine varying from 3.25 to 80 mg daily over periods of from 14 to 21 days. Expressed on the basis of the 100-g rat, the mean value for the weight of liver fat for the control animals was found to be 1.077 g as compared with 2.02 g for the animals which received cystine. It appeared that the addition of cystine approximately doubled the amount of fat deposited in the liver.

**The effect of various facts in the production of dietary fatty livers, H. J. CHANNON and H. WILKINSON (*Biochem. Jour.*, 30 (1936), No. 6, pp. 1033-1039).**—Following the experimental procedure of the study noted above, the authors tested various fats in the low choline diet containing 40 percent of fat and 5 percent of casein. The total lipoids present in the livers corresponding to the various fats at the end of 14 days were butterfat 30.67, beef fat 27.05, palm oil 26.35, coconut oil 20.54, olive oil 15.57, and cod-liver oil 7.18 percent of the fresh liver weight. The total lipoids were fractionated into phosphatide and glyceride fractions, and the fatty acids from all the fractions were analyzed by the Twitchell procedure and the iodine value and molecular weight were determined. The results indicated that the nature of the fat in the livers was markedly influenced by that of the dietary fat.

**Further observations on the effect of dietary caseinogen in the prevention of fatty livers, A. W. BEESTON, H. J. CHANNON, J. V. LOACH, and H. WILKINSON (*Biochem. Jour.*, 30 (1936), No. 6, pp. 1040-1046).**—In continuation of the studies noted above with rats receiving diets containing 40 percent of fat and 5 percent of casein, experiments were carried out to determine the preventive action of casein equivalent to that of choline, to study the effect of marmite on the degree of fat accumulation in the liver, and to determine the minimum amount of choline contained in the experimental diet which exercised an effect on liver fat deposition. Varying percentages of choline chloride were added to the diet, supplemented by marmite for some groups of rats. Two groups of rats received, with and without marmite, the experimental diet in which an additional 25 parts of casein had replaced an equivalent amount of glucose.

The results showed that 1 g of casein is equivalent in its preventive action on liver fat deposition to from 7 to 8 mg of choline. Marmite did not exert any effect other than that due to the choline content. In the experimental diet containing 5 percent of casein, 3 mg of choline a day exerted a marked preventive action and reduced the liver fat deposition from 20 to 10 percent.

**Studies on endemic and experimental goitre, C. E. HERCUS and H. D. PURVES (*Jour. Hyg. [London]*, 36 (1936), No. 2, pp. 182-203).**—The reports of previous goiter studies (E. S. R., 69, p. 315) are continued in this report of a survey in certain New Zealand districts and in the islands of Samoa showing the urinary excretion of iodine. The relationship between the incidence of goiter and the lack of iodine is discussed. The results obtained support the belief that a low iodine intake is a prerequisite for the production of goiter. Including in their survey the determinations made by other workers on the daily urinary iodine excreted in goitrous and nongoitrous regions, the authors conclude that the critical level of iodine intake sufficient to prevent goiter is between 120 $\gamma$  and 160 $\gamma$  per day. The level of iodine intake was found to be low in the districts surveyed. The studies in New Plymouth and Taranaki indicate that a high content of iodine in the soil does not necessarily ensure an adequate iodine intake. Recommendations for improving the regulations as to the sale and use of iodized salt are outlined.

**Lactobacillus acidophilus in dental caries, M. M. JOHNSTON, C. H. M. WILLIAMS, P. G. ANDERSON, T. G. H. DRAKE, F. F. TISDALL, and M. J. KAAKE (*Jour. Amer. Dental Assoc.*, 23 (1936), No. 8, pp. 1493-1497).**—This study was undertaken to determine whether *L. acidophilus* is a specific etiologic factor in dental caries. Bunting and his associates, who had previously reported that in active caries there is a significant growth of *L. acidophilus* which is not found in the absence of active lesions (E. S. R., 70, p. 571), cooperated in this study.

Throughout 1 yr. bacteriologic cultures of the mouth were taken from a group of 39 children. Careful clinical and roentgenologic dental examinations were made independently at the beginning and end of the year by both groups of workers with identical results. Nine children in the group had progressive dental caries, 1 marked and 8 slight cases. Among the group exhibiting progressive caries, *L. acidophilus* was continuously absent in 2 cases. In 27 cases with no evidence of progressive caries, *L. acidophilus* was continuously present in only 1 case. In this group *L. acidophilus* was sporadically present in 8 cases, but infrequently in 7 of these cases. No agglutinins, precipitins, or inhibitory bodies for *L. acidophilus* were found in the saliva samples of negative cases.

**Symposium on nutrition and the deficiency diseases** (*New England Jour. Med.*, 215 (1936), No. 25, pp. 1147-1168, figs. [4]).—This symposium, held at the tercentenary session of the Harvard Medical School on September 14, 1936, consisted of the following papers: Harvard and Nutrition, by G. R. Minot (pp. 1147-1149); Extracellular Fluid and Its Maintenance, by J. L. Gamble (pp. 1150-1152); Protein Deficiency, by C. M. Jones (pp. 1152-1155); Mechanism of Hemoglobin Deficiency, by C. W. Heath (pp. 1155-1157); The Relationship of Defective Nutrition to Changes in the Gastrointestinal Tract, by W. B. Castle (p. 1158); Vitamin C and the Formation of Intercellular Material, by S. B. Wolbach (pp. 1158, 1159); Progress in the Early Recognition of Vitamin Deficiency States, by K. D. Blackfan (pp. 1159-1163); The Relation of Avitaminosis to Oral Pathology, by P. R. Howe (pp. 1163, 1164); Nerve Disorders Arising From Defective Nutrition, by M. B. Strauss (pp. 1164-1166); and Protamine Insulin and Its Advantages, by E. P. Joslin (pp. 1166-1168).

**Diseases of metabolism and nutrition, I, II** (*Arch. Int. Med.*, 57 (1936), No. 2, pp. 422-471, fig. 1).—This review consists of two parts as follows:

I. *Diseases of metabolism*, R. M. Wilder (pp. 422-446).—This part of the review deals almost exclusively with the recent advances made in the study and treatment of diabetes mellitus and associated disorders and diabetes insipidus.

II. *Nutrition*, D. L. Wilbur (pp. 446-471).—Recent progress in the study of the vitamins, the discussions on calcium, phosphorus, iron, and copper metabolism and dental caries, is summarized.

**Susceptibility of different strains of rats to nutritional cataract**, H. S. MITCHELL. (*Jour. Nutr.*, 12 (1936), No. 5, pp. 447-453, fig. 1).—Casual observations of various investigators suggesting differences in the susceptibility of various strains of rats to nutritional cataract on diets high in lactose or galactose (E. S. R., 74, p. 418) led the author to make further observations at the Massachusetts Experiment Station on the response of several different strains of rats to diets containing, respectively, 70 percent of lactose, 35 of galactose, and 70 percent of starch as the carbohydrate source.

In rats of the Battle Creek strain, in which the condition was first noted by the author, cataract developed in 82 percent of the 52 males studied and in 89 percent of the 46 females, while in rats of the Michigan State College strain the incidence was only 10 percent of 10 rats and of the Wistar strain 9 percent of 11 rats. The average lengths of time for the development of mature cataract were 44, 45, 56, and 97 days, respectively.

On the 35-percent galactose diet there was a 100 percent incidence of cataract in the Battle Creek and Michigan College strains, but only 60 percent among 10 animals of the Wistar strain and 83 percent among 15 of the Johns Hopkins strain. The number of days required for the development of mature cataract in five groups were 16, 17, 32, 29, and 23 days, respectively. On diets containing 70 percent of starch no cataracts developed.

Growth was normal on the galactose but slightly retarded on the lactose diet. There was no apparent diarrhea or intestinal disturbance in the rats on the 35-

percent galactose diet and a more or less severe diarrhea on the lactose diet. The severity of the intestinal disturbance, however, showed no correlation with the cataractous changes.

It is noted that cataract development is more rapid in young rats than in older ones, and consequently the age at which the animals are started on the experimental diets must be kept constant if results are to be consistent.

## TEXTILES AND CLOTHING

**The technology of washing,** J. T. HOLDEN and J. N. VOWLER (*London: Brit. Launderers' Res. Assoc., 1935, pp. VII+184, figs. 7*).—This volume, with a preface by F. C. Harwood, is compiled for use by laundry executives and technologists and deals with the problems of the wash house. The material was gained from research studies made by the authors and others and from technical reports issued by the British Launderers' Research Association. The subjects discussed include white-work washing processes, bleaching, bluing, starching, the use of acids, laundering of woollens and silks, processes for colored goods and special goods such as curtains, stain removal, and water treatments. The appendix contains information on instruments in the wash house, water and bleach testing (with a list of the chemical solutions and apparatus required), and an index of the laundry supply houses.

**Research groups study peroxide clarifier,** J. F. OESTERLING and P. B. MACK (*Laundry Age, 16 (1936), No. 5, pp. 14, 16, 87, figs. 4*).—The authors at the Pennsylvania State College studied the efficiency of hydrogen peroxide as a bleach in the laundry process. The results of the tests show that when correct bleaching conditions are maintained hydrogen peroxide is as good as chlorine bleach for whiteness retention and stain removal, and it causes less general damage to the strength of cotton fabrics. The best conditions for bleaching are pH 9.0-9.5 when used with a carbonate type of alkali and pH 10.0-10.5 when used with sodium metasilicate, a temperature not in excess of from 150° to 160° F., and a concentration between  $\frac{2}{3}$  and 2 qt. of hydrogen peroxide, containing 1 percent of available oxygen, to each 100 lb. of fabric.

**More about bleaching,** J. F. OESTERLING and P. B. MACK (*Laundry Age, 16 (1936), No. 6, pp. 58, 60, 62, 64, figs. 2*).—Continuing their studies, as noted above, the authors discuss the chemistry of bleaching and review their research studies on bleaching reagents. Eighteen squares of cotton fabric, containing different stains, were assembled into a composite strip. Sample strips were treated in the laboratory with chlorine bleach and with hydrogen peroxide bleach separately. Stain removal tests were made in commercial laundry plants, using chlorine, hydrogen peroxide, and sodium perborate bleaches. In both laboratory and plant tests the stains used were beverages, fruit juices, inks, salve, iron rust, hair lotion, dye, grass, blood, iodine, and huckleberry.

The results of the commercial plant tests were almost identical, and it was concluded that equally good stain removal efficiencies can be obtained with the three bleaches if good bleaching conditions are maintained and a correct washing procedure is followed. Based on the results of the laboratory and plant tests, the optimum conditions for chlorine bleaching are as follows: The use of 2 qt. or less of sodium hypochlorite solution, containing 1 percent available chlorine, per 100 lb. of fabric, a temperature not in excess of 150°-160° F., a pH of 10.0-10.5, and a time period of 10-15 min. The optimum conditions for hydrogen peroxide bleaching are given in the preceding paper. A special type of blue which will wash out with soap and alkali is used with hydrogen peroxide bleach. The temperature should be lowered when bleaching

colored fabrics, particularly those containing fugitive dyes, with hydrogen peroxide. The pH should not exceed 9.0-9.5 when hydrogen peroxide is employed in the bleaching of silks and woollens.

## HOME MANAGEMENT AND EQUIPMENT

**Housewifery: A textbook of practical housekeeping**, L. R. BALDERSTON (*Chicago: J. B. Lippincott Co., 1936, 5. ed., rev., pp. XI+352, [pls. 2], figs. 174*).—This edition of the handbook of practical housekeeping (*E. S. R., 41, p. 97*) contains extensive references to recent scientific and technical material and presents new illustrations, technics, and equipment.

## MISCELLANEOUS

**Application of statistical methods to agricultural research**, H. H. LOVE (*Shanghai: Commercial Press, Ltd., 1936, pp. [IX]+501, figs. [34]*).—This book sets forth the fundamentals of statistical analysis, including the application of the experimental error concept and the method of variance analysis.

**Statistical methods for research workers**, R. A. FISHER (*Edinburgh: Oliver & Boyd, 1936, 6. ed., rev. and enl., pp. XIII+339, figs. 12*).—The revised edition of this book (*E. S. R., 74, p. 179*) includes new tests for homogeneity, sampling errors estimated by regression, and the extended use of successive summation in fitting polynomials.

**Forty-ninth Annual Report, Colorado Experiment Station, [1936]**, E. P. SANDSTEN (*Colorado Sta. Rpt. 1936, pp. 44, fig. 1*).—The experimental work not previously referred to is for the most part noted elsewhere in this issue.

**Forty-eighth Annual Report [of Texas Station], 1935**, A. B. CONNER ET AL. (*Texas Sta. Rpt. 1935, pp. 294*).—The experimental work not previously reported is for the most part noted elsewhere in this issue.

**Fifty years of field experiments at the Woburn Experimental Station**, E. J. RUSSELL and J. A. VOELCKER (*London and New York: Longmans, Green & Co., [1936], pp. XVII+392, pls. [4], figs. 42; rev. in Nature [London], 139 (1937, No. 3509, pp. 171, 172)*).—This book is discussed editorially on page 433.

## NOTES

---

**Kansas College and Station.**—A new physiological laboratory has been fitted up for the veterinary division which provides greatly improved facilities.

Herbert F. Roberts, head of the department of botany from 1901 to 1919 and subsequently assistant professor of botany in the University of Manitoba, died January 15 at the age of 76 years. He was a native of Kansas, receiving the A. B. degree from the university in 1891 and the M. S. degree from the college in 1898. From 1910 to 1919, he was in charge of experimental plant breeding in the station. In the words of a recent tribute in *Kansas Industrialist*, he had a world-wide reputation as "a botanist and plant breeder, taking part in the development of Kanred wheat and several other strains of Kansan wheats well suited to the Great Plains wheat belt."

**Kentucky University and Station.**—New buildings have been authorized for the coming year to cost \$1,093,000. Among the new structures is a home economics, bacteriology, and zoology building to cost \$185,000.

H. H. Thornberry, assistant plant pathologist, resigned December 31, 1936.

**Massachusetts College.**—Kenneth C. MacArthur has been appointed assistant professor of rural sociology.

**Nebraska University and Station.**—Lawrence Bruner, connected with the entomological work of the institution from 1888 to 1921, since 1895 as professor of entomology, died January 30, aged 80 years. A native of Pennsylvania, he received the honorary B. S. degree from the university in 1897. He had specialized on orthopteroid insects, particularly the locusts, which he studied extensively in Argentina and other South American countries.

**Cornell University.**—Cyrus R. Crosby, extension professor of entomology since 1913, died January 11 at the age of 58 years. A native of New York, he was graduated from the university in 1905 and subsequently continuously identified with its instruction and extension work.

**Virginia Station.**—Dr. A. L. Grizzard, associate agronomist, resigned December 31, 1936. Dr. W. L. Threlkeld, assistant professor of zoology, has been appointed assistant zoologist, and A. G. Smith, Jr., associate horticulturist.

**New Journals.**—*The Journal of Marketing* is being issued quarterly at 383 Madison Avenue, New York City. It succeeds *The National Marketing Review* and *The American Marketing Journal* as the result of a merger on January 1, 1937, of the American Marketing Society and the National Association of Marketing Teachers into the American Marketing Association. The initial number contains book reviews, notes, and a number of original articles, among which are the following: The Consumer and the Agricultural Adjustment Administration, by D. S. Anderson (pp. 3-9); Notes on the Measurement of Consumers' Attitudes, by H. K. Nixon (pp. 13-19); Where Are We Bound in Marketing Research? by F. R. Coutant (pp. 28-34); Market Research in Germany, by K. Brandt (pp. 35-39); and Progress in Marketing Research, by M. D. Taylor (pp. 56-64).

*Rivista di Parassitologia* is being published quarterly at Via G. B. Martini 6, Roma, chiefly for original contributions in protozoology, helminthology, and entomology. All articles in the initial number are in Italian, but a distinctive feature is the inclusion of English and German summaries.

# EXPERIMENT STATION RECORD

VOL. 76

MAY 1937

No. 5

## THE DEATH OF BLACKWELL OF OKLAHOMA AND NIELSON OF NEW JERSEY

Agricultural experiment stations, like other research institutions, rely for their success primarily on the faithful and efficient labors of the men and women associated with them. Their organization is more or less complex, and they are served in various ways. To them, of course, the investigator is fundamental, but administration and support are also vital, and when these are effectively rendered the gain to the stations and to the world is great.

These observations are put forward at this time because of two recent losses from the station ranks. One of these was Director Carl P. Blackwell of Oklahoma, who died in his fifty-first year on March 4, 1937. The other, on February 19, was Mr. James Nielson, 92 years of age, active in the founding of the New Jersey Experiment Station in 1880 and continuously thereafter a member of its governing body.

Director Blackwell was born in Lampasas, Tex., on November 5, 1886, reared on a farm, and graduated from the Oklahoma A. and M. College in 1911. Aside from an interlude of study at the University of Wisconsin leading to the M. S. degree in 1915 and an assistantship in field crops in Cornell University in 1917-18, his life was spent in the South. Beginning as instructor and adjunct professor in agronomy in the University of Texas (1914-17), he became in turn professor of agronomy in Clemson College and agronomist in the South Carolina Station (1918-25), agronomist of the soil improvement committee of the National Fertilizer Association (1925-28), and dean of agriculture and director of the station in Oklahoma since 1929 (with leave of absence in 1935 as regional director of the land utilization section of the U. S. Resettlement Administration).

The personal contribution of Director Blackwell to research was restricted mainly to his creditable service as an agronomist. As an administrator he had demonstrated his effectiveness under difficult conditions. His initial report from Oklahoma deplored the frequent previous changes in personnel, and he had made definite progress in the task of stabilization and improvement to which he had pledged himself. His research program made substantial provision

for basic studies, but was also fully cognizant of immediate needs. He was notably successful in increasing the contacts of the station with the people of the State, one effective medium being the attractive and informing series of reports which he issued under the titles of *Research Leads to Farm Progress*, *Solving Oklahoma Farm Problems*, *Applying Science to Agriculture*, and *Science Serving Agriculture*. He was highly regarded throughout the South, and of increasing influence in the Association of Land-Grant Colleges and Universities, serving as secretary and chairman of its experiment station section in 1933 and 1934. Occurring at a time when many years of usefulness seemingly lay before him, his death has ended a career of considerable accomplishment and much promise.

The long life of Mr. Nielson was closely identified with a single institution—Rutgers College. Graduating there in 1866, he continued his residence in New Brunswick and his association with Dr. George H. Cook, who had recently been appointed professor of the theory and practice of agriculture. In 1870 and again in 1878, these two made extensive visits to Europe, studying agricultural institutions and bringing back with them seed of the soybean from Bayern (Bavaria) and Wien (Vienna) as well as plans for assisting agriculture by organized experimentation. Eventually their efforts in the latter direction were rewarded by the establishment in 1880 of the New Jersey State Experiment Station. Two years previously Mr. Nielson had been appointed a member of the board of visitors of the College of Agriculture, and thereby he then became one of the board of managers of the station. He was soon elected secretary and treasurer. Thereafter his interest was unfailing and his services as varied as were the needs.

In 1883 he helped to defeat a bill to repeal the act creating the station. He gave a plot of ground as a site for the station building, and later made gifts and loans of additional land and purebred stock. Upon the death of Dr. Cook he served as acting director for more than 2 years, leaving the station in 1893, in the words of its history, "in spite of uncertainty and lack of a long-time program . . . a stronger institution than he found it." In 1910 he was appointed vice president of the board of managers and in 1913 president, serving in the latter capacity for nearly 25 years.

Mr. Nielson also generously aided other branches of Rutgers, endowing the College for Women and giving the Nielson campus and athletic field. His sustained interest was reattested by his will, leaving \$50,000 as a student loan fund to the College for Women and his entire residuary estate, estimated at \$500,000, to the university. Characteristically self-effacing and never patronizing, he was a true patron of education and agriculture.

## RECENT WORK IN AGRICULTURAL SCIENCE

### AGRICULTURAL AND BIOLOGICAL CHEMISTRY

[Chemical research work of the Bureau of Chemistry and Soils, 1936] (*U. S. Dept. Agr., Bur. Chem. and Soils Rpt., 1936, pp. 3-29*).—The carbohydrate investigations have included work on sugarcane and cane sugar, sugarcane sirup, sorgo sirup, beet sugar, honey, milk-sugar products, levulose and arabinose, and sweetpotato starch. In food research data were obtained on microbial food spoilage, cucumber pickles, wines and fruit brandy, staling of bakery products, waxlike coatings of fruits, toxicity of fluorine compounds and other insecticides, rancidity, lecithin in soybeans, special breads, egg preservation, plant pigments, apple powder and other deciduous fruit products, loosening the hulls of walnuts, citrus fruit products, enzyme studies, and preservation of fruits and vegetables by freezing. The industrial farm products research has included work on cellulose, utilization of farm wastes by destructive distillation and by fermentation, lignin, mold fermentation products from corn sugar, chemical weed killers, fast dyes for agricultural fibers, biological stains, mildew-proofing of farm fabrics, preservatives for hides and skins, tanning materials, and leather. Under naval stores research are considered the topics chemistry of turpentine and rosin and the technology of naval stores. The oil, fat, and wax investigations dealt with black-walnut oil, raisin-seed oil, tung and other drying oils, miscellaneous seed oils, and halibut-liver oil. The protein and nutrition investigations covered the digestibility of proteins; cystine, tryptophan, and tyrosine content of proteins; proteins in locust bark; safflower-seed meal; amino acid content of wheat; and selenium in toxic wheat.

[Chemical and bacteriological investigations by the Michigan Station] (*Michigan Sta. [Bien.] Rpt. 1935-36, pp. 14, 15, 16, 22, 23, 24*).—The report contains brief notes on the following topics: Cucumber fermentation, yeast studies, a micromethod for the determination of lead, analysis of sugar beets and Michigan wheats and flours, methods for the determination of potassium and sodium, copper, and fluorine, and bacteriological methods of water analysis.

[Chemical and bacteriological researches of the New York State Station] (*New York State Sta. Rpt. 1936, pp. 18, 19, 26, 36-38, 40, 41, 46, 47*).—Notes are given on the following topics: Fruit juice preservation, sauerkraut investigations, identification of yeasts, bacteria causing lactic fermentations, fruit juices (including grape juice, rhubarb juice, apple juice, and cherry juice), fermented fruit juices, pectin and pectic enzymes, new analytical reagents for sodium and potassium, protein investigations (including casein plastics and influence of salts on the properties of gelatin).

The refractivity of protein solutions, D. B. HAND (*Jour. Biol. Chem., 108 (1935), No. 3, pp. 703-707*).—A contribution from Cornell University calls attention to the fact that in the equation for the refractive index of a protein solution,  $n_p - n_s = a \times C$ , in which  $n_p$  is the index for the protein solution,  $n_s$  is the index for the solvent,  $C$  is the concentration in grams per 100 cc of

solution, and  $\alpha$  is a proportionality constant, sometimes called the specific refractive increment, "the proportionality constant has been erroneously considered by all authors as being characteristic of the individual proteins. . .

"Although  $\alpha$  is not characteristic of the individual protein, it is possible to write equation 1 [above stated] in a form in which a characteristic constant does appear and which is independent of the refractivity of the solvent. If we assume that equation 1 is valid for solutions of all concentrations, we can extrapolate to solutions containing only protein. At this point the refractivity of the solution,  $n_{ps}$ , would be equal to the refractivity,  $n_p$ , of the pure protein in the dissolved state, and the concentration would equal 133 g of protein per 100 cc (density of protein is 1.33). Then, from equation 1,  $n_p - n_s = 133\alpha$  and  $\alpha = (n_p - n_s)/133$  [equation] (2).

"It is an experimental fact that  $\alpha$  varies with the refractivity of the solvent and that the calculated values of  $n_p$  are independent of the solvent in many instances and are characteristic of the individual protein. . . Although the values for  $\alpha$  vary greatly from solvent to solvent, the extrapolated figure for pure protein in solution,  $n_p$ , is practically independent of acid, alkali, sodium chloride, and ammonium sulfate. However, alcohol and acetone actually decrease the refraction of serum globulin, increase slightly the refraction of casein, and have no effect on the refraction of gliadin. Phenol depresses the refraction of gliadin markedly. It is possible that these solvents dehydrate the protein so that the refractivity shifts toward that of the dry protein. This seems the more likely since dry protein has a different density from dissolved protein. The values of  $n_p$  are probably accurate to  $\pm 0.01$ ."

It is emphasized that "no physical significance should be attributed to  $n_p$ . We have no data which would justify extrapolation beyond the small range of concentrations which have been studied experimentally. The fact that  $n_p$  is a constant characteristic of the protein does not prove the validity of the assumption used in deriving equation 2. The value  $n_p$  is proposed as an empirical convenience for describing the rate with which the refraction of protein solutions changes with concentration when the refractivity of the solvent is taken into consideration."

**Glutamine and asparagine in tobacco leaves**, H. B. VICKERY and G. W. PUCHER (*Jour. Biol. Chem.*, 113 (1936), No. 1, pp. 157-160).—In an investigation carried out at the Connecticut [New Haven] Experiment Station it has been shown that glutamine occurs, together with asparagine, in considerable quantities in the leaves of the tobacco plant, an observation which furnishes an explanation of the production of ammonia when tobacco plant tissue is treated with boiling water. It is pointed out, however, that "this observation does not exclude the possibility that other amides, or amidelike substances, may also be present", and the importance to the understanding of the amide metabolism of plants of further qualitative study is emphasized.

**The component fatty acids of goat milk fat**, R. W. RIEMENSCHNEIDER and N. R. ELLIS (*Jour. Biol. Chem.*, 113 (1936), No. 1, pp. 219-233, fig. 1).—At the U. S. D. A. Bureau of Animal Industry, a composite sample of fat from goat milk, amounting to 3.5 k, was converted to methyl esters and fractionated into 63 fractions for determination of the component fatty acids.

A study of the distillation data indicated the presence of decenoic, tetradecenoic, palmitoleic, oleic, caproic, caprylic, capric, myristic, palmitic, and stearic acids. Subsequent examination of the fractions established the presence of these acids and also of arachidonic acid. Traces of an octabromide of an unknown acid were found (probably a  $C_{24}$  acid or an impure isomer of arachidonic acid). A mixture of saturated acids with higher molecular weight than stearic acid was isolated, consisting principally of tetracosanoic acid along

with traces of cerotic acid. Estimations on the content of the component fatty acids present show general agreement with previously published analyses except for the absence of linoleic acid and the presence of small percentages of decenoic, tetradecenoic, and hexadecenoic acids.

**Some products of partial hydrolysis of silk fibroin**, R. L. GRANT and H. B. LEWIS (*Jour. Biol. Chem.*, 108 (1935), No. 3, pp. 667-673).—The authors subjected silk to hydrolysis at 30° C. with 70 percent sulfuric acid for from 65 to 70 min. and studied the products of hydrolysis.

"It has been possible to obtain two peptones of widely different composition. The first had a low amino nitrogen content and a content of tyrosine higher than that of the original silk. The second contained more amino nitrogen (10 to 17 percent of the total nitrogen) and tyrosine in amounts similar to many of the more common types of proteins (2.5 to 5.7 percent)."

**Enzymatic hydrolysis of starch in pectic extractions from apple pomace**, G. L. BAKER (*Delaware Sta. Bul.* 203 (1936), pp. 21, 22).—The author reports results of further experiments (E. S. R., 74, p. 4).

**The purification and properties of lysozyme**, K. MEYER, R. THOMPSON, J. W. PALMER, and D. KHORAZO (*Jour. Biol. Chem.*, 113 (1936), No. 1, pp. 303-309).—The authors report upon a study of the preparation of the bacteriolytic principle, lysozyme, from acetone-dried egg white.

"Lysozyme can best be freed from the tenaciously adhering mucoid in the extracts by precipitation with flavianic acid. Lysozyme is apparently a basic polypeptide, having a nitrogen content of 15.3 percent and giving a number of protein reactions. From the presence of sulfhydryl, its inactivation by alkali, peroxide, iodine, and cuprous oxide, and its reactivation by hydrogen sulfide, sulfite, and hydrogen cyanide, it is concluded that lysozyme acts only in the reduced state."

**Purification of the antihemorrhagic vitamin**, H. J. ALMQUIST (*Jour. Biol. Chem.*, 114 (1936), No. 1, pp. 241-245).—This contribution deals with the purification and concentration of the antihemorrhagic vitamin as contained in a hexane extract of alfalfa meal, with a brief summary on the known properties of this product.

**Purification of the antihemorrhagic vitamin by distillation**, H. J. ALMQUIST (*Jour. Biol. Chem.*, 115 (1936), No. 2, pp. 589-591).—Dealing with the antihemorrhagic vitamin concentrate as described above, a method is given for further concentration and purification of the product by distillation under a high vacuum. A distillate fraction of yellow oil obtained at 120°-145° was found to be at least four times as potent as the original concentrate. The requirement of the chick is not more than 0.5  $\mu$ g (microgram) of this product per gram of diet.

**Provitamin D potencies, absorption spectra, and chemical properties of heat-treated cholesterol**, M. L. HATHAWAY and F. C. KOCH (*Jour. Biol. Chem.*, 108 (1935), No. 3, pp. 773-782, pls. 2).—Detailed experimental evidence obtained at the University of Chicago shows that although the fractionation methods used are "far from quantitative", the authors have been able to obtain from heat-treated cholesterol crude fractions of different provitamin D activities, depending on the temperature and time of heating and the solvent used.

**Effect of sulfur sprays on corrosion of prune cans**, E. H. WIEGAND, D. E. BULLIS, and M. B. HATCH (*Oregon Sta. Bul.* 345 (1936), pp. 42, figs. 10).—The quantity of sulfur introduced into the can by prunes that have been sprayed or dusted according to prevailing orchard practices was found to be less than 0.3 part sulfur per 1,000,000 parts of can contents). Corrosion caused by this minute amount of sulfur was confined principally to enameled and reenameled

coke-plate cans, in which cases failures were generally less for the washed than for the unwashed fruit. This study indicates that the amounts of spray materials when properly applied do not introduce into the cans sufficient residue to be a factor in causing corrosion. Corrosion in the various sprayed lots closely paralleled that observed in the respective control packs.

A marked benefit was obtained by using a better grade of plate. In all cases the "charcoal" plate was found superior to the "coke" plate. The two tin plates used were both coated on the same high-grade soft steel, but the coke plate had a light tin coating, whereas the charcoal plate had a heavier coating. In most instances the enamel on coke plate caused more rapid spoilage. This is tentatively attributed to intensively localized action on the tin and iron where defects occur in the enamel coating. Sirup packs tended to corrode more rapidly than the water packs.

"Sulfur compounds, with the exception of sodium sulfite, added directly to the can in larger amounts [10 p. p. m.] proved to be very active in producing corrosion. This is attributed to the relatively large quantities added compared to the amounts introduced through spraying."

**A new and easy method for the potentiometric determination of calcium concentrations in solutions**, H. J. C. TENDELOO (*Jour. Biol. Chem.*, **113** (1936), No. 1, pp. 333-339, fig. 1).—The author finds that  $\text{CaF}_2$  electrode can be used at calcium concentrations of 1 milliequivalent per liter and higher to determine potentiometrically concentrations of calcium in solutions and in protein sols.

It was shown that calcium is adsorbed by proteins and that the adsorption decreases with increasing acidity of the protein sols.

It is pointed out that "the use of  $\text{CaF}_2$  as an electrode provides the great advantage that no foreign substances are introduced into the systems to be studied, as is the case when electrodes of the second or third order are used."

**Modifications of the bipyridine method for available iron**, G. O. KOHLER, C. A. ELVEHJEM, and E. B. HART (*Jour. Biol. Chem.*, **113** (1936), No. 1, pp. 49-53).—At the Wisconsin Experiment station the bipyridine method (E. S. R., **64**, p. 712) has been modified to render it applicable for the determination of available iron in pigmented plant tissues, and a further modification of the same method is applicable to fresh animal tissues. The figures obtained in the examination of a number of food substances are tabulated.

**Determination of the mineral content of the soil absorbing complex**, E. TRUOG and M. DROSDOFF (*3. Internatl. Cong. Soil Sci., Oxford, Eng., 1935, Trans., vol. 1, pp. 92-95*).—A brief discussion contributed from the University of Wisconsin takes up separation of free silica, alumina, and ferric oxide; evidence indicating the presence of muscovite and talc in soil colloids; chemical composition of base-exchange compounds; and the mineral compounds of soil colloids. An "outline of procedure for determination of mineral content of inorganic soil colloid" is given under the subheads (1) separation and determination of free silica and free alumina, (2) separation and determination of free iron oxide, (3) removal of free sulfur introduced under (2), (4) determination of exchange capacity, (5) saturation of muscovite to normal potash content, (6) total analysis, and (7) stoichiometric allocations.

**A method for the simultaneous determination of organic carbon and the "oxidation value" of soil organic matter**, I. V. TYUBIN (*3. Internatl. Cong. Soil Sci., Oxford, Eng., 1935, Trans., vol. 1, pp. 111-113*).—The author suggests that the volumetric chromate method for the approximate determination of organic carbon may be used to study the degree of oxidation of the soil organic matter by measuring simultaneously the amount of carbon dioxide

evolved. "If the carbon dioxide is equivalent to the amount of chromic acid reduced, then the corresponding organic matter may be assumed to have the composition  $C_2H_{2m}O_m$ . If more carbon dioxide is evolved the composition may be written  $C_2H_{2m}O_{m+x}$  and, if less,  $C_2H_{2m}O_{m-y}$ . Provisionally we may assume that the first case corresponds to a normal degree of oxidation of the organic matter, and we may expect the differences between the carbon dioxide evolved (1) and the oxygen required from the dichromate (2) to show the nature of the soil organic matter and to characterize the conditions of its formation."

Some of the data obtained in this manner by the author are given.

**First report of the Organic Carbon Committee, E. M. CROWTHER (3. *Internatl. Cong. Soil Sci., Oxford, Eng., 1935, Trans., vol. 1, pp. 114-127*).—**Nine soils were analyzed for organic carbon by several methods at 11 laboratories.

The dry combustion results by a number of methods gave such concordant results that the choice between these methods is probably to be made on the grounds of laboratory convenience. The removal of carbonates by repeated treatment with sulfurous acid solution gave results agreeing with those from separate determinations of total and inorganic carbon. In wet combustions the recoveries of carbon varied with the details of the technic. By one method the recoveries for eight soils fell between 99 and 103 percent, except for one calcareous soil which gave only 90 percent recovery. A number of rapid chromic acid or dichromate titration methods gave useful approximate results when corrected by an appropriate factor. Chlorides in two of the soils interfered seriously with many of the analyses.

**Note on the amide nitrogen of some soils of the tropical regions [trans. title], M. RIGOTARD (3. *Internatl. Cong. Soil Sci., Oxford, Eng., 1935, Trans., vol. 1, pp. 108, 109*).—**Noting that organic nitrogen is ordinarily determined only in its total quantity, with little or no attention to the amide fraction of the total organic nitrogen, the author emphasizes the possible significance of the last-named datum, outlines a provisional method consisting essentially in the extraction of the soil with 1 percent aqueous hydrochloric acid at room temperature and the determination, by the Kjeldahl method, of the nitrogen content of this extract, and gives the figures obtained in the examination of Cambodge, Cochinchina, and Annam soils. In the samples for which the data are here tabulated, the amide nitrogen was found to constitute from 13.9 to 28 percent of the total nitrogen.

**A method for determining the degree of humification of the soil, W. SIBIRSKY (3. *Internatl. Cong. Soil Sci., Oxford, Eng., 1935, Trans., vol. 1, pp. 110, 111*).—**As a reagent capable of dissolving the more completely humified portion of the soil organic matter and leaving the undecomposed substances intact, the author used a hypochlorite solution made by passing chlorine through  $N$  NaOH (1.040 sp. gr.) at 5° C. until the density reached 1.050 (5.5 l or 17.4 g chlorine per 500 cc  $N$  NaOH). Fresh solutions were used in the work described, "but the solutions may be preserved for periods up to 1 mo. by using paraffined vessels, closed by a stopper with a soda-lime tube, and stored in darkness at a temperature below 10°. Chlorates and a moderate alkalinity do not interfere with the methods.

"[A sample amounting to] 0.5 g soil is ground in an agate mortar, dried at 100°, and treated in a 150-cc beaker with 20 cc of water and 50 cc of the hypochlorite solution. Care must be taken to prevent loss by foaming. The mixture is heated on a boiling water bath for half an hour with stirring, and then boiled for 5 min. The residual hypochlorite is decomposed by neutralizing with concentrated hydrochloric acid, which is added drop by drop until effervescence stops and the solution clears. The beaker is allowed to stand in hot water until

the solution is completely clear, and the residue is transferred to a Gooch crucible and washed with hot water, containing a trace of nitric acid, until chlorides are completely removed. The crucible is dried to constant weight at 100°. The filtrate is concentrated to about 100 cc, neutralized with ammonia, and treated with 15–20 cc N  $(\text{NH}_4)_2\text{CO}_3$  and, after the precipitate has settled, with N  $(\text{NH}_4)_2\text{C}_2\text{O}_4$ . After standing in a warm place the precipitate is filtered off, washed with hot water containing  $(\text{NH}_4)_2\text{CO}_3$ , and ignited. The weight of the precipitate is added to that of the treated soil and the total loss on oxidation determined. Soluble salts should also be determined if their amount is appreciable."

This method was found to give somewhat lower results than does the 6 percent hydrogen peroxide method, the last-named reagent having been found to oxidize more of the cellulose than does the hypochlorite reagent.

On the question of the determination of the "root-soluble" soil phosphoric acid by the citric acid method [trans. title], M. GRAČANIN (3. *Internatl. Cong. Soil Sci., Oxford, Eng., 1935, Trans., vol. 1, pp. 97–99*).—In view of the well-known fact that the solubility of phosphates in buffer solutions depends quite as much upon the H-ion concentration of the solution as upon the titratable acidity of the organic acid, on the ground of other theoretical considerations and by reason of the results of comparative experiments on a number of soils the author concludes that the determination of "available" phosphoric acid by means of a 1 percent solution of citric acid has neither experimental nor theoretical justification.

Report of the Soil Reaction Committee on the investigation of the glass electrode method, D. J. HISSINK (3. *Internatl. Cong. Soil Sci., Oxford, Eng., 1935, Trans., vol. 1, pp. 127–132*).—The glass electrode method proved satisfactory on all soils tested. It was found that the agreement between the quinhydrone and the glass electrode methods is satisfactory for soils without quinhydrone drift, i. e., for soils which give closely similar potentials about 10 and 60 sec. after adding the quinhydrone. "For soils with quinhydrone drift the glass electrode results are similar to those measured by quinhydrone after about 10 sec. Such rapid measurements by quinhydrone are not reproducible, and for soils with large quinhydrone drifts the pH values should be measured by the glass electrode. In order to decide whether the quinhydrone method is appropriate, determinations should always be made rapidly (preferably within 10 sec.) and again after 60 sec., and the latter readings used when the drift is small."

The quantitative determination of chlorophyll by means of the photoelectric colorimeter of Lange [trans. title], T. N. GODNEW and S. W. KALISCHIEWICZ (*Planta, Arch. Wiss. Bot., 25 (1936), No. 2, pp. 194–196, fig. 1*).—The authors briefly discuss the literature on quantitative determination of chlorophyll, and from their own experiments, three of which are here noted, they conclude that with the Lange colorimeter this may be done directly in acetone extracts with extraordinary rapidity and exactness.

The determination of some amino acids in crystalline pepsin, H. O. CALVERY, R. M. HERRIOTT, and J. H. NORTHCROP (*Jour. Biol. Chem., 113 (1936), No. 1, pp. 11–14*).—In a crystalline pepsin preparation the author determined total nitrogen, amino nitrogen (before and after acid hydrolysis), humin nitrogen, amide nitrogen, tyrosine, tryptophan, cystine, arginine, histidine, lysine, aspartic acid, and glutamic acid.

During heat coagulation at pH 4 there was partial destruction of the pepsin molecule, and "on analysis of the coagulated material and the noncoagulable material for the above substances differences were observed." Of amino nitro

gen determined after acid hydrolysis, of amide nitrogen, and of tyrosine, cystine, and arginine, the coagulum contained appreciably less than did the noncoagulable material. The lysine and glutamic acid figures, on the other hand, are higher in the case of the coagulum than in that of the noncoagulable material.

**A method to determine small amounts of citric acid in biological material.** G. W. PUCHER, C. C. SHERMAN, and H. B. VICKERY (*Jour. Biol. Chem.*, 113 (1936), No. 1, pp. 235-245).—At the Connecticut [New Haven] Experiment Station it has been shown that quantities of citric acid of the order 0.1 to 1 mg can be determined with an accuracy of  $\pm 5$  percent by oxidation and bromination to form pentabromoacetone and conversion of this substance by means of sodium sulfide to a colored material that is suitable for estimation in the Pulfrich spectrophotometer. Data obtained in the application of the method to the analysis of blood, urine, feces, and of both animal and plant tissues are given.

**Determination of free and combined cholesterol in bile.** C. RIEGEL and H. J. ROSE (*Jour. Biol. Chem.*, 113 (1936), No. 1, pp. 117-124).—A method for the determination in bile of from 0.5 to 5 mg of cholesterol (free and combined), which is "simple and accurate to  $\pm 5$  percent", is described.

**The determination of carotene and xanthophyll by a single distribution between liquid phases.** S. W. CLAUSEN and A. B. MCCOORD (*Jour. Biol. Chem.*, 113 (1936), No. 1, pp. 89-104, figs. 2).—A general theory for the quantitative estimation of two substances having the same color by a single distribution between two immiscible liquids is outlined. The conditions for the application of the theory to the analysis of mixtures of pure carotene and xanthophyll are established. The solvents between which carotene and xanthophyll were distributed most advantageously for the purposes of the method described were hexane and diacetone alcohol. Precautions which must be taken when other substances are present are given. The application of the method to the analysis of blood plasma and serum is detailed.

**Estimation of vitamin A** [trans. title], G. BALASSA and G. SZÁNTÓ (*Hoppe-Seyler's Ztschr. Physiol. Chem.*, 240 (1936), No. 1-2, pp. 29-32, figs. 2).—The authors review the methods used for estimating vitamin A and show that the Rosenthal reaction (E. S. R., 72, p. 739), or their modification of it by omitting the gualacol, can be used for the determination of vitamin A in concentrates. For matching the color produced, a 0.02-percent solution of the dyestuff "Parabraun Z extra" was satisfactory. This reaction cannot be used for determinations on tissue extracts since cholesterol gives a red color.

**The quantitative determination of vitamin K.**—I, F. SCHØNHEYDER (*Biochem. Jour.*, 30 (1936), No. 5, pp. 890-896, fig. 1).—Continuing the investigation by Dam on the antihemorrhagic vitamin of the chick (vitamin K) (E. S. R., 74, p. 682), a test for its quantitative determination is described. This is a curative method, a unit of vitamin K being defined as the smallest daily dose of a test substance per gram of chicken given for 3 days which is able to reduce the *S* value from over 1,500 to 10. The *S* value is a quantitative expression of the degree of sickness of the animal based on the comparative concentration of a clotting agent required to clot diseased and normal bloods within a given time. The methods for drawing blood from the carotid artery, determining the coagulation time, and calculating the *S* value are described.

**The occurrence and chemical nature of vitamin K.** H. DAM and F. SCHØNHEYDER (*Biochem. Jour.*, 30 (1936), No. 5, pp. 897-901).—This contribution establishes green vegetables as particularly rich sources of vitamin K. With regard to the chemical nature of this vitamin, using extracts of hog-

liver fat, it is shown to be quite thermostable. Its potency is greatly reduced by cold saponification and completely destroyed by saponification. Continued exposure to light and air also greatly reduced its potency, although it is not determined whether this was due to the action of light or to rancidity. Acetone has proved to be a particularly good solvent for extraction of the product. Adsorption on aluminum oxide, calcium carbonate, or cane sugar proved effective methods of concentrating the vitamin.

**Deterioration of book and record papers**, T. D. JARRELL, J. M. HANKINS, and F. P. VERTCH (*U. S. Dept. Agr., Tech. Bul. 541 (1936), pp. 20, figs. 4*).—The authors made tests of the physical condition and determined some of the chemical constituents of papers ranging in age from 19 to 169 years and compared the results with those of like tests on a new record paper. Edges of pages were found in general to yield a water extract of lower pH value, to show a higher content of absorbed acidic sulfur compounds taken up from the air, and to have a lower bursting and folding strength than did the centers of the pages. The weaker papers showed slightly higher copper numbers. In general, the papers with the highest acidity, as indicated by the pH of the water extract, suffered the greatest deterioration.

"These findings emphasize the need of further research to devise means of preventing or retarding deterioration caused by the presence of excessive quantities of aluminum sulfate and/or by the absorption of acidic sulfur compounds from the air. Libraries, especially those in cities and near coal-burning plants, should be so constructed as to permit conditioning and purifying of the air with which they are supplied. On the other hand, the incorporation in paper of suitable materials, such as a basic filler, to neutralize or counteract acidic gaseous sulfur compounds as such compounds come into contact with the paper may, it seems reasonable to think, decidedly prolong the life and serviceability of valuable book and record papers."

## AGRICULTURAL METEOROLOGY

**Advances and developments in weather forecasting**, R. H. WEIGHTMAN (*Jour. Franklin Inst.*, 222 (1936), No. 5, pp. 527-550, figs. 9).—This article deals especially with the influence of the Bjerknes cyclone model, air mass analysis, and Petterssen's kinematical methods on weather forecasting.

The author says: "As we review the progress in forecasting, it is apparent that very definite and decided advances have been made since the World War due largely to the more complete and more numerous observations in the free air. The more complete understanding of the genesis and maintenance of the high and low pressure systems which we now think of in terms of air masses and interactions between them, together with a better knowledge of the physical processes involved in the causation of precipitation, has been aided in great measure by the introduction of the Bjerknes cyclone model and in the last several years by Petterssen's kinematical methods of forecasting the movement and changes in intensity of the pressure systems and fronts."

**Long-period prediction of crop yields in Germany** [trans. title], L. GÖSELE (*Ber. Verhandl. Sachs. Akad. Wiss. Leipzig, Math.-Phys. Kl.*, 85 (1935), No. 2, pp. 121-144, figs. 8; *abs. in Jour. Landw.*, 84 (1936), No. 3, pp. 253, 254; *Met. Ztschr. [Braunschweig]*, 53 (1936), No. 10, pp. 397, 398).—The author concludes that from a statistical study of the relation of weather to crop yields over long periods, it may be possible in many cases to make long-time forecasts of yields of grain in Germany.

**Weather and wheat yield in western Canada.**—II, Influence of pre-seasonal precipitation on plot yields; III, Relation between precipitation and agricultural yield, J. W. HOPKINS (*Canad. Jour. Res.*, 14 (1936), No. 6, Sect. C, pp. 229-244, fig. 1).—In continuation of previous statistical studies (E. S. R., 73, p. 801), there was found to be "a significant relation between pre-seasonal precipitation and the yield secured from year to year on both the fallowed and stubble plats of a summer fallow-wheat-wheat rotation, above-average moisture being associated with increased yields. The annual yields of Marquis wheat from more fertile summer-fallowed varietal test plats were not, however, significantly correlated with pre-seasonal precipitation, nor was there any consistent relation between this weather factor and the relative yield of certain early, medium-early, and late-maturing varieties. The annual average yield of wheat per acre from 1916-34 in three central and in three southern crop districts of Saskatchewan and Alberta showed a significant positive correlation with the available statistics of rainfall between May 1 and July 31. Yields in the southern districts were also positively correlated with pre-seasonal precipitation, whereas those in the central districts were not. The degree of association ( $R=0.74$ , central; and  $0.79$ , southern) was not adequate for the practical forecasting of annual production, but may be improved by refinements dependent on the accumulation of additional observational data."

**Evaporation and rainfall studies in the northwest Minnesota lake region**, J. C. JENSEN (*Amer. Phil. Soc. Proc.*, 76 (1936), No. 5, pp. 747-759, figs. 5).—The stated object of the study here reported was to determine, if possible, whether there are well-defined though small increases in the thunderstorm precipitation within a distance of 20 to 30 miles from water areas of considerable extent. The area selected for the study was the lake region in northeastern South Dakota and in the vicinity of Dawson, N. Dak. It was found that very considerable quantities of moisture are evaporated from lakes and ponds under hot-wind conditions. Such bodies of water can increase the relative humidity by 16 percent and the absolute humidity by 29 percent, at the same time lowering the temperature of the air  $9^{\circ}$  F., and may result in a considerable increase in precipitation.

**The duty of rainfall for sugar cane**, A. GORDON (*Sugar News*, 17 (1936), No. 7, pp. 277-282, figs. 4).—The importance of proper amount and distribution of rainfall in sugarcane production is pointed out. In tables and graphs it is shown that when the annual rainfall is about 100 in. or less sugarcane production is relatively high. On the other hand, when the annual rainfall is much higher than 100 in. the production is relatively low. When seasonal rainfall (November 1 to March 31) is less than 20 in. the production is relatively high, and when it is over 20 in. the production is relatively low. For purposes of crop prediction the seasonal rainfall may be taken instead of annual rainfall. In this way a prediction on crop production of the coming season is possible immediately after the milling season is over.

**Frost warning experts go far afield to gather their prediction material**, A. J. CONNOR and D. C. ARCHIBALD (*Country Life Brit. Columbia*, 20 (1936), No. 10, pp. 9, 16).—The frost-warning service recently set up in Canada is described.

**Frost penetration in cultivated soil** [trans. title], O. FRANCK (*Meddel. Centralanst. Försöksv. Jordbruksområdet [Sweden]*, No. 462, (1936), pp. 37, figs. 11; *Eng. abs.*, pp. 35-37).—Thickness and looseness of snow cover were found to be a decisive influence on the depths to which soil will freeze. Frost penetration was found to be deeper in sandy and peat soils than in clayey soils. Frost penetrated deeper in naked ground than in ground covered by vegetation,

and deeper in untilled than in tilled soils. It disappeared first in sandy soils, a little later in clayey soils, and last in peat soils. In naked soil it disappeared earlier than in soil covered by vegetation.

**Monthly Weather Review** [September-October 1936], (*U. S. Mo. Weather Rev.*, 64 (1936), Nos. 9, pp. 287-317, pls. 11, figs. 5; 10, pp. 319-350, pls. 9, figs. 5).—In addition to the usual detailed summaries of climatological data, solar and aerological observations, observations on weather on the Atlantic and Pacific Oceans and on rivers and floods, and bibliographical and other information, these numbers contain the following contributions:

*No. 9.*—Precipitation on the Islands Along the Chinese Coast, by J. Lee (pp. 287-291); Climate of the Rogue River Valley, Oreg., by W. B. Merriam (pp. 291-294); Gall's Projection for World Maps, by I. R. Tannehill and E. W. Woolard (pp. 294-297; and Tropical Disturbances, September 1936, by I. R. Tannehill (pp. 297-299).

*No. 10.*—Methods of Evaluating Ultra-Violet Solar Radiation in Absolute Units, by W. W. Coblenz (pp. 319-321); The Geometrical Theory of Halos, I, by E. W. Woolard (pp. 321-325); Wind and Minimum Temperature in the Redlands, California, Fruit-Frost District, by J. Janofsky (pp. 325-329); and Tropical Disturbance, October 9-10, 1936, by I. R. Tannehill (p. 329).

**Meteorological observations [1936]**, C. I. GUNNESS ET AL., (*Massachusetts Sta. Met. Ser. Buls.* 565-576 (1936), pp. 4 each).—These are the usual summaries of observations for each month at Amherst, Mass., with brief notes on the more significant features.

The December number contains an annual summary for 1936 which shows that the mean pressure for the year was 30.02 in.; the mean temperature 47.9° F., as compared with the normal of 47.2°, highest 98° July 8, lowest -12° February 20; total precipitation 48.24 in., as compared with the normal of 43.49 in., snowfall 47.5 in., as compared with the normal of 48.38 in.; mean cloudiness 52.7 percent, bright sunshine 55.4 percent; last frost in spring May 22, first in fall September 26; last snow April 2, first November 24.

**Eight-year temperature variation** [trans. title], F. HUMMEL (*Gerlands Beitr. Geophysik.*, 48 (1936), No. 2-3, pp. 268-302, figs. 14; *Eng. abs.*, p. 268; *abs. in Sci. Abs.*, Sect. A—Phys., 39 (1936), No. 466, p. 1073).—A study of observations during 40 yr. at Karlsruhe, checked by observations during 134 yr. at Berlin, indicates an 8-yr. period of variations in frequency of frost days in March, the amplitude of which appears to vary with a period of 68-70 yr. and to be connected with the number of sunspots.

**Meteorological and phenological observations in the Horo Experimental Forest, 1935** (*Saghalien Cent. Expt. Sta., Ann. Rpt. Met. and Phenol. Observ. Horo Expt. Forest*, 5 (1935), pp. [6]+55).—Observations under spruce-fir cover and in the open showed the mean air temperature in winter to be slightly higher in general under cover than in the open. During the rest of the year it was cooler, although the annual mean temperature was nearly the same. Monthly means of maximum air temperature were slightly lower under cover than in the open, but minimum air temperatures were somewhat higher. The annual temperature range was 2° C. less under cover than in the open. The mean annual relative humidity was 4 percent higher under cover than in the open throughout the year. Summer precipitation and evaporation under cover were about two-thirds and one-third, respectively, of those in the open, and wind velocity in summer under cover was as low as one-eighth of that in the open.

[**Agricultural meteorology in India**], C. W. B. NORMAND (*India Met. Dept. Rpt. 1934-35*, pp. 16-18, pl. 1; *abs. in Nature* [London], 138 (1936), No. 3480, p. 70).—Researches carried on in 1934-35 (E. S. R., 74, p. 8), especially under

the auspices of the Central Agricultural Meteorological Observatory situated on the farm of the Agricultural College, Poona, are reviewed. These "included precision observations on the growth of wheat and on the study of the microclimate of that crop . . . and a study of (1) the microclimate within the first few feet above the ground in the open, (2) the microclimate inside crops, (3) the thermal balance at the surface of the ground, (4) evaporation from soil and free water surfaces, (5) radiation from the sun, the sky, and the earth's surface, (6) soil temperature in relation to soil color and moisture at the surface and lower depths, (7) percolation of water through different depths of soil, (8) exchange of moisture between air and soil during clear weather, and (9) meteorological factors in relation to incidence of frost during winter in India." Statistical studies of the relation of weather to yields of wheat, cotton, and other crops are also referred to, as well as effective rainfall and meteorological factors involved in weather forecasting.

### SOILS—FERTILIZERS

[Bureau of Chemistry and Soils soil and fertilizer investigations] (*U. S. Dept. Agr., Bur. Chem. and Soils Rpt., 1936, pp. 32-45*).—The fertilizer investigations included work on nitrogen (catalysis in nitrogen fertilizer investigations, physical constants of gases and fertilizer salts, nitrogenous fertilizer materials, and biochemical and organic nitrogen investigations), potash production, phosphates, and mixed-fertilizer technology. Data are also given on selenium investigations, soil colloid investigations, nonfertile soils, soils from erosion experiment stations, peat and muck investigations, and the soil survey.

[Soil work of the Arkansas Station] (*Arkansas Sta. Bul. 337 (1936), pp. 26-29*).—Soil work is discussed by R. P. Bartholomew under the heads, availability of rock phosphate and the role of potassium, and erosion control by Bartholomew, D. C. Carter, L. C. Kapp, and W. C. Hulburt.

[Soil investigations by the Delaware Station] (*Delaware Sta. Bul. 203 (1936), pp. 14-16, 22, 41, 42*).—Very brief summaries are given on the influence of lime on the availability of potash, by H. C. Harris; the effect of fertilizers and cropping upon the nature and amount of electro-dialyzable bases in the soil with particular reference to potassium, by G. M. Gilligan; and copper sulfate as a plant nutrient, by T. F. Manns, R. Russell, and W. Churchman.

[Fertilizer investigations by the Michigan Station] (*Michigan Sta. [Blen.] Rpt. 1935-36, pp. 49-51*).—Concise summaries are presented under the headings fertilizer increases Upper Peninsula crops, grass responds earlier to mineral than to organic nitrogen, fertilizer placement, spring fertilization of fall grains, and effect of fertilization on leaf surface of beans.

[Missouri soil and fertilizer investigations] (*Missouri Sta. Bul. 370 (1936), pp. 75-81*).—Results are given briefly on fertilizers for cotton, soil erosion, the productivity of Missouri pastures, and rotation and fertilizer experiments, Sanborn field and south field, all by M. F. Miller and H. H. Krusekopf; nitrogen and carbon accumulation in the soil, by Miller, W. A. Albrecht, and H. Jenny; aggregation of desert and brown forest soils, and factors contributing to the genesis of soil microstructure, both by L. D. Baver; surface behavior in the hydration of clays and swelling of colloidal aluminosilicates, both by Baver and H. Winterkorn; calcium content of soils and the effect of long continued soil treatments upon bacterial activity, both by Albrecht; and base exchange and stability of colloidal systems, by Jenny and R. F. Reitemeier.

Soil survey of Wheeler County, Texas, A. H. BEAN ET AL. (*U. S. Dept. Agr., Bur. Chem. and Soils [Soil Survey Rpt.], Ser. 1932, No. 10, pp. 34, figs. 3, map 1*).—Wheeler County consists of 585,600 acres of "a rolling and hilly,

quickly drained, sandy plain which, in many places where the surface is unprotected, is subject to severe erosion by water and wind. The surface relief is featured by many short drainageways, large dunellike areas, and bodies of severely eroded soils."

The soils studied were found to form 13 series, including 19 types, of which Abilene loamy fine sand, 22.3 percent of the total area of the county, is the most extensive. Miles fine sandy loam covers 20 percent and Miles fine sand 17.1 percent.

**Selenium occurrence in certain soils in the United States, with a discussion of related topics.—Second report, H. G. BYERS** (*U. S. Dept. Agr., Tech. Bul. 530* (1936), pp. 79, figs. 10).—The present bulletin summarizes the work of 1935 in continuation of that noted previously (*E. S. R.*, 74, p. 102).

The existence of large areas of land containing sufficient selenium to produce toxic vegetation in the area surrounding the Black Hills, in western Colorado, in portions of the valleys of the Uncompahgre, Gunnison, and Colorado Rivers, in a portion of western Kansas, and in certain portions of Montana has been demonstrated. The data show that in these seleniferous areas not all the vegetation is toxic and that the degree of toxicity varies within wide limits for given plants, even for soils of similar selenium content, and also for different plants upon the same soil; that irrigation, with underdrainage, tends to diminish the selenium content of the soil; and that, if the irrigation water contains sulfates, irrigation diminishes the selenium content of the vegetation.

Data indicating a close relationship between the selenium content of soil and of the soil parent material are presented. "The parent material so far demonstrated as producing toxic soils appears to be limited to the lower portion of the Pierre and the upper portion of the Niobrara formations and the corresponding Cretaceous formations named otherwise. It is not asserted that toxic conditions are limited to these formations."

**A photoelectric method for mechanical analysis, E. G. RICHARDSON** (*3. Internatl. Cong. Soil Sci., Oxford, Eng., 1935, Trans., vol. 1, pp. 40, 41*).—The "constant time" and "constant depth" methods here noted have been more fully noted from another source (*E. S. R.*, 73, p. 15).

**The effect of temperature in the mechanical analysis of soils** (trans. title], **M. GRACANIN** (*3. Internatl. Cong. Soil Sci., Oxford, Eng., 1935, Trans., vol. 1, pp. 34-38*).—The author shows that temperature has an important influence upon the sedimentation and dispersion processes in the mechanical analysis of soils, that when ammonium hydroxide is used as the dispersing agent the sedimentation rate and the dispersion are both increased but are not equally affected, and that as a result mechanical analyses of soil are comparable only when carried out at a single and constant sedimentation temperature and with the use of the same method for the preparation of the soil for analysis.

**Results given by the citrate method for the mechanical analysis of soils and sediments** [trans. title], **A. DEMOLON and E. BASTISSE** (*3. Internatl. Cong. Soil Sci., Oxford, Eng., 1935, Trans., vol. 1, pp. 33, 34*).—The authors have developed, for the determination of the clay fraction, a method dependent upon the peptizing action of the citric anion, using a sodium citrate solution containing 10 milliequivalents per liter. Comparing this procedure with the International method, they obtained the same results in the examination of Podzols, Brown soils, slightly calcareous Red soils, soils having but slightly alterable skeleton of granitic origin, muds, alluviums, and plastic clays.

In calcareous sediments, however, the citrate method gave results lower than those given by the standard method. The authors found that in this case the solution of the calcium carbonate sets free colloids not preexistent

in the soil and not properly to be considered a part of the clay fraction of the soil in its natural state. The authors applied the International method to the residue remaining after an extraction of the colloids by the citrate method from a Limagne soil having andesitic skeletal material and obtained a significant further colloidal fraction. They found that this further fraction had a composition different from that of a fraction peptized by the citrate solution and point out that the supplementary fraction should be regarded as an artifact.

In the case of lateritic soils the authors found their method to be at fault in that in this case they observed a prolonged, gradual disintegration before obtaining complete dispersion. For the dispersion of such soils they prefer a sodium hydroxide solution, 1 g per liter, heating the soil with this solution for 1 hr. on a water bath.

They discuss also the composition of the extracted clay colloids.

**The determination by optical means of the gels and gel mixtures which appear in the course of the process of weathering** [trans. title], J. H. HELLMERS (3, *Internatl. Cong. Soil Sci., Oxford, Eng., 1935, Trans., vol. 1, pp. 80-82*).—The author points out that in the usual petrographic study of the soil the more or less weathered individual minerals are examined, whereas little attention is given to the newly formed gels and gel mixtures. By reason of the great importance of these gels for the characterization of a soil, omission of their consideration deprives the microscopic study of a soil of half its possible value. Since a knowledge of the refractive indices of the pure gels is prerequisite for their identification in soils, the author has examined silica and clay gels at various percentages of moisture content and very briefly reports upon such measurements. He also calls attention to the modifying influence of other soil components, and especially to the difficulties introduced by adsorbed iron hydroxide and humic colloids. The refractive indices of silica and clay gels were found to rise with the increasing intensity of coloration by these adsorbed substances, but a satisfactory determination of the character of the gel under examination could be made when they were only lightly colored.

**A study of the adsorption complex of mineral soils**, D. J. HISSINK, J. VAN DER SPEK, and S. B. HOOGHOUT (3, *Internatl. Cong. Soil Sci., Oxford, Eng., 1935, Trans., vol. 1, pp. 82-84*).—The study here discussed was carried out upon four fractions having particles  $2\mu$  or less in diameter, from  $2\mu$  to  $8\mu$ , from  $8\mu$  to  $16\mu$ , and from  $16\mu$  to  $43\mu$ . These fractions were freed from bases by electrodialysis, in which connection it is noted that "to prevent decomposition of the aluminosilicate complex it is absolutely necessary that the suspension to be dialyzed should not contain any humic matter." The values of  $x$  and  $y$  in the molecular ratio  $Al_2O_3, x SiO_2, y H_2O$ , the total adsorptive capacity for bases as indicated by the baryta method, and some other data are presented and discussed.

**The identification of the clay substance of soils by means of roentgen ray investigations** [trans. title], A. JACOB, U. HOFMANN, and H. LOOFMANN (3, *Internatl. Cong. Soil Sci., Oxford, Eng., 1935, Trans., vol. 1, pp. 85-88*).—The authors discuss briefly the significance of X-ray spectrographic investigations on bentonites and ceramic clays which indicate that the sorptive complex of soils consists of crystalline substances including kaolinite, montmorillonite, and halloysite.

**Some properties of clay fractions**, C. E. MARSHALL (3, *Internatl. Cong. Soil Sci., Oxford, Eng., 1935, Trans., vol. 1, pp. 88-90*).—The author stresses the fundamental importance, in an attempt to formulate a theory of soil formation, of the question "what is clay?" Until this basic question "has been satisfac-

torily answered it seems, to put it mildly, extremely rash to propound complex theories of soil formation processes." The possibility of obtaining fractions of 50- $\mu$  particle size is mentioned in a brief indication of the methods used for the mechanical analysis of the clays studied. The present paper summarizes a study of the mineralogical character and chemical composition of clay fractions having particle sizes ranging from 2 $\mu$  down to less than 100  $\mu$ .

"One fact of general importance has emerged. Even in the most homogeneous clay (a bentonite) the proportionate increase in exchange capacity is much less than the proportional increase in the outer surface of the particles. This lends additional support to the view, already widely held, that a large proportion of the exchangeable cations are held inside the clay lattice. The evidence of the double refraction experiments is that the cations have definite places in this lattice."

**Cataphoresis in soil science, A. REIFENBERG** (3. *Internatl. Cong. Soil. Sci., Oxford, Eng., 1935, Trans., vol. 1, pp. 38-40*).—Testing his technic with kaolin, the author obtained the greatest charge and cataphoretic movement of the material by dispersion in 0.002 N sodium hydroxide. He was able to effect a quantitative determination of soil colloids by this means. He reports also a "cataphoretic determination of fertilizer requirements", noting, in part, that "the greatest difficulty in chemical examination for the availability of nutrients in soils consists in separating the nutrients available for plant life from the sum total of potash and phosphates present. In free solution or adsorbed to colloids such salts are easily available to plants."

"During cataphoresis phosphates in free solution or adsorbed to colloids move to the anode. The same is true with potash adsorbed to colloids, whereas in free solution it moves to the cathode. (Part of the potash may also move to the cathode, since some electrolysis takes place.) We therefore succeed by cataphoresis in separating the potash and phosphates available for plants. For this purpose potash present in both tubes and phosphate in the anode tube has to be determined." Satisfactory agreement with the Neubauer (E. S. R., 53, p. 319) indications of plant food availabilities were obtained, but "it should be emphasized, however, that much more experimental data should be collected to test the value of the cataphoresis method for the determination of available nutrients."

**On the formation of structure in soil.—I, The structure of soil colloids, D. I. SIDERI** (*Soil Sci., 42 (1936), No. 5, pp. 381-393, pl. 1*).—"The existence of aggregate phases in soil colloids alters essentially our conceptions regarding their behavior. The electric properties of colloid particles, when they agglomerate into groups, are radically changed as a result of the shrinking of the ion envelope. The properties determined by the nature of the absorbed cations are leveled out in the associated groups. The possibility of spontaneous coagulation, explained by the prevalence of the forces of molecular attraction over those of electrostatic repulsion, is demonstrated."

**The affinity of the soil colloids for cations and anions, J. N. MUKHERJEE** (3. *Internatl. Cong. Soil Sci., Oxford, Eng., 1935, Trans., vol. 1, pp. 90-92*).—"It appears that in discussing the properties of colloidal acids and bases, such as occur in soil, it is necessary to distinguish between their sol and gel conditions and the state of aggregation of the primary particles. Colloidal acids present special features which require that they should be treated on a basis different from acids in true solution. The total acid taking part in the interaction with an alkali above pH 7 is often a variable quantity as the particles dissolve. Besides, the intensity of the adsorption of cation is a factor which also determines the amount of acid taking part in the reaction. It appears

from measurements of specific conductivities and of the free acidity and also from the nature of the titration curves that they behave simultaneously as a weak and as a strong acid. . . . The process of liberation of acid or alkali by the interaction of a neutral salt with gels requires to be distinguished from that of sols. In the case of sols useful information regarding the affinity relationships has been obtained by titration with different alkalies, neutral salts of strong and weak acids, and strong and weak acids. Measurements of the number of particles per unit volume appear to be necessary. Simultaneous cataphoretic measurements are also helpful in this connection. The adsorbability of different ions determined from such measurements offer a quantitative measure of the affinity constants. The titration curves with strong acids and alkalies give an idea of the stability of the constituent alumina and silica in the clay complex. Information as to the free amounts of alumina and silica can also be obtained." Other factors affecting the behavior of colloidal acids and bases and methods for their investigation are outlined.

**Flotation applied to the study of soil colloids, N. K. KRUPSKY (3, *Internat. Cong. Soil Sci., Oxford, Eng., 1935, Trans., vol. 1, pp. 46-48*).—**The author prepared humus sols by saturating Chernozem, "alkali" soil, and degraded Chernozem with the ammonium ion, and clay suspensions from the alluvial horizon of a dark-gray forest loam and from a kaolin. Studying the behavior of such preparations when brought into contact with various polar and nonpolar liquids, he found, in part, that:

"The behavior of different fractions of soil colloids on the dividing surface separating two liquids, of which one is more polar than the other, is not the same. Under corresponding conditions organic colloids are easily wetted by less polar liquids, when leaving a hydrous medium. Mineral colloids are more easily wetted by more polar liquids (in this case with water) and always remain in hydrous phase.

"At or near the neutral reaction the particles of humus soil are not wetted by faintly polar liquids. During the process of acidification humus rapidly becomes hydrophobic, and below the limit of coagulation the humus entirely passes into nonhydrous phase. During the process of acidification the double electrical layer is progressively destroyed, which facilitates the wetting of the surface of humus particle by faintly polar liquids. Wetting with nonpolar liquids and the removal of humus from the hydrous medium may also be brought about in neutral or alkaline conditions. To do this a third liquid must be added to a system of hydrous and nonhydrous phases, this third liquid mixing in any proportions with either liquid composing the system (such as ethyl alcohol, acetone, etc.). By replacing water in hydrated film of micelle, this liquid facilitates the wetting of the surface of a humus particle with faintly polar liquid. Highly alkaline humus also partly passes into the nonhydrous phase, even without applying an auxiliary dehydrator. Hence it is obvious that humus is a typical hydrophobic colloid. Most of the surface of the humus particle must be of carbonlike properties."

Numerous further observations of a similar nature are also recorded.

**The adsorption of liquids by clays, E. W. RUSSELL (3, *Internat. Cong. Soil. Sci., Oxford, Eng., 1935, Trans., vol. 1, pp. 48-50*).—**A contribution from the Rothamsted Experimental Station presents an analysis of the factors on which the apparent specific volume (or density) of a clay in different liquids depends.

"The results of this analysis are in accord with the hypothesis that clays adsorb nonpolar liquids only weakly, if at all, but that the adsorption of polar liquids is due to the orientation of the electric dipoles in their molecules in the

electrostatic fields around the exchangeable ions held by the clay and around the negative charges on the clay substrate."

**The sorption of gases upon soil constituents and soils** [trans. title], H. WIESSMANN and W. NEUMANN (*3. Internatl. Cong. Soil Sci., Oxford, Eng., 1935, Trans., vol. 1, pp. 51-53*).—The authors call attention to the fact that, although the sorption of ions from the aqueous phases in soils has been under careful investigation for years, the sorption of gases has been given scant notice. The soil constituents, the sorptive behavior of which was studied in the experiments here reported, included silicic acid, clay, iron oxide, and the carbonate and sulfate of calcium. The gases of which the sorption was measured were nitrogen and oxygen separately considered, air, carbon dioxide, and ammonia.

When the soil constituents named were used in their crystalline condition neither nitrogen nor oxygen showed any detectable sorption, even when the solids were reduced to a particle diameter of about 0.02 mm. When colloidal preparations of the sorbents were used, a vigorous sorption of nitrogen, oxygen, and air took place. The data indicated a behavior in accordance with Henry's law. The absolute magnitude of the sorption reached values of the order of  $3 \times 10^{-5}$  mols per 100 g of sorbent at an equilibrium pressure of 1 atmosphere.

The water content of the sorbents markedly affected the results, the extent of the sorption increasing sharply with the progressive dehydration of the sorbent.

The sorption of carbon dioxide and of ammonia ranged from 20 to 400 times that of the nitrogen and oxygen, indicating that "chemisorption" played an important part in the process insofar as these two gases were concerned.

**Surface pressure, sorption, and resistance to wetting** [trans. title], F. ZUNKER (*3. Internatl. Cong. Soil Sci., Oxford, Eng., 1935, Trans., vol. 1, pp. 53-58*).—The author points out the important influence of surface pressure upon soils and plants and discusses theoretical considerations from which this value may be calculated, arriving at the expressions  $P = K \left( 1 - \frac{r}{R} \right)$  for bodies of

convex curvature and  $P = K \left( 1 + \frac{r}{R} \right)$  for concave curvatures,  $R$  being the radius of curvature in either case,  $K$  the internal pressure, and  $r$  the molecular distance of the surface molecules, while the value of  $K$  is derived from the surface tension,  $\alpha$ , by means of the relation  $K = \frac{2\alpha}{r}$ . He also finds that the surface pressure at the plane surface of a solid may be determined from the marginal angle formed by a drop of a liquid of known internal pressure when such a drop is brought into contact with the surface. The relation found to hold good in this

case is  $K_s = \frac{2 K_l}{1 + \left( \frac{1}{\sin \Psi} - \frac{1}{\tan \Psi} \right)}$ .

The author further discusses the relation of surface pressure to adsorption and to the resistance to wetting. He defines resistance to wetting in terms of surface pressure by stating that if the surface pressure of a solid, such as the soil particle, is less than that of the liquid which comes into contact with it, there is a non-capillary relationship between solid and liquid, or a resistance of the solid to wetting by that liquid.

**On the conformity of base-exchange phenomena to physicochemical laws** [trans. title], F. ALTEN and B. KURMIES (*3. Internatl. Cong. Soil Sci., Oxford, Eng., 1935, Trans., vol. 1, pp. 59-62*).—From the experimental data and results of theoretical calculations here discussed the authors conclude that the observed facts are in general in good agreement with electrochemical theory. A number of base-exchange experiments are briefly summarized, some of them leading to the conclusion that aluminum is bound in the sorption complex in the

ionogenic state and is capable of direct exchange with the cations of neutral salts.

**Soil : water ratios in base exchange**, H. GREENE (*3. Internatl. Cong. Soil Sci., Oxford, Eng., 1935, Trans., vol. 1, pp. 63-65, fig. 1*).—The author shows that changes in the soil : water ratio are responsible for discrepancies which have been noted in the results obtained in the use of an equation intended to represent the course of the base-exchange reaction. He adds that "strictly speaking it is the colloid : water ratio rather than the soil : water ratio that should be held constant." He further points out that "as a minor modification of technic it is advisable to use widely different amounts of ammonium chloride as displacing agent, say 100 and 800 m[illigram] eq[uivalents] per 100 g soil."

**The pH and base saturation of the Podzol profile**, S. MATTSO ( *3. Internatl. Cong. Soil Sci., Oxford, Eng., 1935, Trans., vol. 1, pp. 67-70*).—The author determined the pH of a number of Podzols on sand and sandy moraine in their natural state and after the soils had been rendered completely unsaturated by electrodialysis. "The results bring out the remarkable fact that the actual pH is in general lower than the ultimate pH in the C and B horizons of the Podzol profile." He further calls attention to the fact that "it is generally assumed that the soil in the lower Podzol horizons is more saturated with bases than the soil in the upper horizons. This has been a quite natural conclusion when based on the difference in pH, but we see now that the facts are what appears to be a paradox—the most acidic upper horizons are also the most saturated with bases . . . The theory of isoelectric weathering . . . not only accounts for the facts here presented but also leads us to the conclusion that it could not be otherwise." The remainder of this brief note amplifies and illustrates the last statement.

**The hydrolysis of calcium carbonate and its relation to the alkalinity of calcareous soils**, T. F. BUEHRER and J. A. WILLIAMS (*Arizona Sta. Tech. Bul. 64 (1936), pp. 41, figs. 13*).—The authors have investigated the behavior of calcium carbonate in soils and the forms in which it occurs.

In calcareous soils, calcium carbonate "probably exists . . . in one or more of the following forms: (1) Calcite; (2) aragonite; (3) basic calcium carbonate:  $\text{CaCO}_3 \cdot \text{Ca}(\text{OH})_2 \cdot x\text{H}_2\text{O}$ ; (4) a double sodium-calcium carbonate:  $\text{CaCO}_3 \cdot \text{Na}_2\text{CO}_3$ ; (5) a highly hydrated, amorphous form resulting from recent precipitation on or between soil particles; (6)  $\text{CaCO}_3$  particles coated with an adsorbed film of a protective organic or inorganic colloid."

Various factors were found to influence the extent of the hydrolysis of calcium carbonate in soils and its effect upon soil reaction. "The effect of neutral salts was to reduce the hydrolysis of calcium carbonate, the order in which the chlorides of calcium, magnesium, potassium, and sodium affected it being approximately that of the lyotropic series. Organic and inorganic colloidal materials are found to decrease the hydrolysis of calcium carbonate markedly. This effect is attributed to the adsorption of a film of the colloidal material, which inhibits the further hydrolysis of the calcium carbonate particles. The soil itself may also adsorb some of the free hydroxyl ions which are present in solution as a result of the hydrolysis. It is suggested that this may account for the fact that some soils containing considerable calcium carbonate may not be appreciably alkaline and even neutral.

"When calcium carbonate is added to alkaline soils, there is no appreciable effect on the pH. In the case of acid soils the effect closely approximates an ordinary electrometric buffer curve for the soil, with a very pronounced increase in pH upon additions up to 10 percent by weight of calcium carbonate, beyond which the pH slowly rises to that of pure calcium carbonate. Buffer titration

curves for calcium carbonate, sodium and calcium bentonites, and for four alkaline calcareous soils were obtained. It was found that the calcium carbonate gives only one inflection point corresponding to the total neutralization of the sample taken. The pH remains constant over an extended series of additions of acid, indicating high buffer capacity. The sodium and calcium bentonites, on the other hand, showed relatively slight buffer action. A correlation of these results with similar curves for soils leads to the conclusion that the buffer capacity of these soils is due in large measure to the calcium carbonate present. This is also substantiated by the fact that the specific buffer capacity of calcareous soils is found to be approximately a linear function of the percentage of calcium carbonate present. Calculations from the ionization constants for carbonic acid, made on the basis of three different assumptions, showed that the first ionization constant reproduces the observed pH values for the buffer titration of calcium carbonate most closely. It is concluded that this equilibrium is the predominant one in determining the pH of calcium carbonate and of soils."

**The influence of certain replaceable bases in the soil upon the elemental composition of vegetable crops**, J. B. HESTER and F. A. SHELTON (*Soil Sci.*, 42 (1936), No. 5, pp. 335-340).—On the basis of analyses made at the Virginia Truck Experiment Station, the authors state that "the presence of a large amount of a particular replaceable base in the soil colloidal complex influenced the elemental composition of plant material even though the yields were affected but little. A high replaceable calcium content suppressed the adsorption of potassium, nitrogen, and magnesium; a high replaceable magnesium content suppressed the absorption of potassium, calcium, and nitrogen; and a high potassium content suppressed the absorption of calcium, magnesium, and nitrogen."

**Soil reaction and total acidity**, F. E. HANCE and L. E. DAVIS (*Hawaii. Planters' Rec. [Hawaii. Sugar Planters' Sta.]*, 40 (1936), No. 4, pp. 319-327).—The authors describe this popular article as "a discussion of soil pH, base exchange, and kindred topics—terms of everyday usage."

**Soil microbiology**, C. THOM (*U. S. Dept. Agr., Bur. Plant Indus. Rpt.*, 1936, pp. 15, 16).—A note is given on the favorable effect of controlled temperature of fermentation upon the formation of composts suitable for mushroom culture and a very brief summary of observations on the bactericidal activities of the ameboid form of the myxomycete *Dictyostelium discoideum* which was found capable of destroying various micro-organisms pathogenic to plants, animals, and man.

**The biological and chemical oxidation of ammonia to nitric acid**, A. S. CORBET (*3. Internat. Cong. Soil Sci., Oxford, Eng., 1936, Trans.*, vol. 1, pp. 133, 134).—The photonitrification of ammonium salts in sterile soils, reported upon by Rao and Dhar (*E. S. R.*, 65, p. 418) and by Dhar et al. (*E. S. R.*, 70, p. 16) [but not detected by Fraps and Sterges (*E. S. R.*, 73, p. 19)], has been "confirmed in a large measure" by the present author's work at Jealott's Hill, England. It has been further established "that nitrite formation can occur in soil exposed to ultraviolet light in the absence of added ammonium salts or photosensitizers." The author further finds that the mechanism of nitrification may be either biological or chemical. It also appeared that under certain conditions the oxidation may proceed through the stages of hydroxylamine and hyponitrous acid, and that, "while the first-named can never have more than an ephemeral existence under the experimental conditions, hyponitrous acid present in the form of the calcium salt may account for as much as 40 percent of the total nitrogen present."

Of the nitrification processes in general, it is the author's opinion that "in soils in temperate regions it seems that the first stage in nitrification is effected by *Nitrosomonas*, or allied organisms, although photonitrification at the surface during the summer months is not precluded. Judging by the results obtained at Jealott's Hill, it appears that *Nitrobacter* is much rarer than the nitrite-forming bacteria, and the oxidation of nitrite in the soil may be largely a consequence of the acid reaction of the medium.

"The extent to which nitrification takes place by a photochemical process in tropical soils remains to be assessed, but in cleared areas in the humid Tropics with a shallow topsoil layer probably photonitrification is an important process. The continual wetting and drying-out which daily takes place in exposed soils in the equatorial belt must be responsible for some nitrite formation. The acid nature of the soils of the humid Tropics effectually insures that there is no nitrite accumulation, and it may well be that here nitrate formation is entirely a chemical process."

**Chemical nitrification in soil**, G. DE' ROSSI (3. *Internatl. Cong. Soil Sci., Oxford, Eng., 1935, Trans., vol. 1, pp. 135-137*).—Referring to the observations of Rao and Dhar (E. S. R., 65, p. 418) with respect to photochemical nitrification, the author finds that heat, rather than light, is the important factor in nonbiological nitrification. He states, in part, that "my work shows that, under perfectly normal conditions, ammonia naturally existent in the soil undergoes a process of oxidation until nitric acid is produced, and this quite independently of any microbiological activities, quite apart from any influence exercised by light. This process, however, is particularly favored by a moderate degree of heat, such as may be experienced in any land through the agency of the sun's rays in the spring, summer, and autumn." He also describes briefly a technic by means of which "a demonstration of this assertion [above quoted] is very simple."

**On the number and variety of nitrifying organisms**, H. WINOGRADSKY (3. *Internatl. Cong. Soil Sci., Oxford, Eng., 1935, Trans., vol. 1, pp. 138-140*).—Noting that a systematic study of the nitrifying microflora has not been made and that a suitable technic has not hitherto been described, the author calls attention to the fact that such a study "has become relatively easy by employing the method of silica-jelly plates, coated with carbonates or kaolin, which has been recently worked out at the laboratory of the Institut Pasteur at Brie-Comte-Robert, [France]." By such means several new genera and species were isolated and characterized and are here briefly described. It is noted that some of the new forms "are very curious from the point of view of bacterial morphology."

**A growth and respiration factor for certain rhizobia**, S. R. HOOVER and F. E. ALLISON (3. *Internatl. Cong. Soil Sci., Oxford, Eng., 1935, Trans., vol. 1, pp. 158-160*).—This note, which is a contribution from the U. S. D. A. Bureau of Chemistry and Soils, outlines some of the authors' observations of the nature and effects of a growth-stimulating factor by the presence of which in small quantities the growth of *Rhizobium trifolii* in synthetic media "is commonly increased 20 to 30 times." The authors designated this substance as "coenzyme-R." They state, in part, that "coenzyme-R occurs not only in legume plants but in practically all natural materials examined. Cane molasses, yeast, soil humate, crude egg albumin, and liver are excellent sources of the material. Its synthesis by the free-living nitrogen fixer *Azotobacter*, which itself has a very high rate of respiration, is especially noteworthy."

**On the decomposition of pentosans by soil and dung micro-organisms**, J. ZIEMIĘCKA (3. *Internatl. Cong. Soil Sci., Oxford, Eng., 1935, Trans., vol. 1,*

pp. 167, 168).—"Pentosan decomposition in nature is due to the action of a specific microflora, which may be composed either of bacteria (rods) or of different kinds of molds (mostly Mucedineae) or of both groups of microorganisms. The process can be accompanied by nitrogen loss and therefore be harmful for the general balance of mineral nitrogen in soils and in manures."

**Antagonistic action of soil microbes with special reference to plant hygiene.** I. HINO (*3. Internatl. Cong. Soil Sci., Oxford, Eng., 1935, Trans., vol. 1, pp. 173, 174*).—The author outlines the results of experiments which he believes to "show the important role of soil microbes in destroying the plant pathogens in the soil, and therefore the possibility of applying the principle in practice in plant hygiene is hopeful. Before making practical applications, however, climatic conditions, water contents, reaction, and other soil properties must be carefully considered, and the microbes which are not antagonistic, or least antagonistic, to the useful soil inhabitants are to be preferred. The protozoa are no doubt very strong in antagonistic action to plant pathogens, though these organisms are not suitable, as their abundant existence and strong activity often induce soil sickness. Soil bacteria and soil fungi are more suitable for the purpose."

**Short-period fluctuations in bacterial numbers in soil.** H. G. THORNTON and C. B. TAYLOR (*3. Internatl. Cong. Soil Sci., Oxford, Eng., 1935, Trans., vol. 1, pp. 175-179, figs. 2*).—The authors discuss the shortcomings of the plate count and the direct microscopic methods for determining bacterial numbers in soils and propose a procedure based, in part, upon that of Conn (E. S. R., 60, p. 20).

"A suspension of indigo particles is made up, and the number of particles per milliliter is determined by a hemocytometer count. A known mass of soil is shaken in a known volume of this counted suspension. Films of the resulting mixture are prepared, dried, and stained with erythrosin. Counts are made of the bacterial cells and of the indigo particles, in random microscope fields, and the numerical ratio of indigo to bacteria is calculated.

"Since the absolute number of indigo particles added per gram of soil is known, the number of bacterial cells is easily calculable. The calculation of bacterial numbers is, of course, independent of the quantity of soil examined. Moreover, because the disturbing influences of drying act alike on the bacteria and on the indigo, the ratios found in replicate microscope fields have a random distribution."

Tests and checks of this method indicated that it "has an accuracy as good as that of the plate method, and, in addition, it gives an estimate of the absolute numbers of stainable bacterial cells. Among its limitations are the facts that it does not indicate whether the stainable cells counted are alive, and that the organisms can be identified only by their cell shapes and size."

This method was applied in the study of short-period fluctuations of bacterial numbers, the counts having been made at 2-hr. intervals.

**The reduction of nitrate by individual strains of free-living bacteria.** J. MEKLEJOHN (*3. Internatl. Cong. Soil Sci., Oxford, Eng., 1935, Trans., vol. 1, pp. 180-183*).—"Eighty free-living strains of bacteria were tested as to their ability to reduce nitrate in synthetic media. Five types of reaction with regard to nitrate were observed: (1) No reduction of nitrate, (2) reduction of part of the nitrate to nitrite, (3) quantitative reduction to nitrite, (4) reduction to nitrite followed by reduction to ammonia, (5) reduction to nitrite followed by evolution of nitrogen gas."

**The effect of different media on soil protozoan counts.** A. DIXON (*3. Internatl. Cong. Soil Sci., Oxford, Eng., 1935, Trans., vol. 1, pp. 179, 180*).—The

author compared two media, "using peptone agar and soil-extract agar for protozoan counts from 55 Russian tobacco soils. The dilution counts were made on each soil sample using peptone agar and soil-extract agar obtained from each individual soil. A more varied protozoan population developed on the soil-extract agar, which gave much higher protozoan numbers than did the peptone agar." Other illustrative observations are mentioned, and the author reaches the conclusion "that the growth of protozoa on soil-extract agar gives a truer picture of the soil protozoan fauna than would be obtained from peptone agar, if used as a medium."

Some observations on the *Aspergillus niger* method, A. M. SMITH (3. *Internatl. Cong. Soil Sci., Oxford, Eng., 1935, Trans., vol. 1, pp. 171-173*).—Dealing with some details of technic, the author has found, in part, that "(1) considerable latitude is permissible in the concentration of inoculum employed without sacrifice of accuracy, (2) ammonium nitrate or sulfate seems to be the best source of nitrogen, (3) the area of growth of the mycelium, i. e., size of vessel, is very important, (4) strain may exert a specific effect upon the results, and there may be an interaction between soil and strain, i. e., different strains may not put a series of soils in the same order of fertility, (5) the development of the fungus is not influenced to a serious extent by the application of lime to the soil in quantities normally used to correct soil acidity, (6) the standard error of experiment is of the order 4 or 5 percent for an individual determination."

The role of the bacteriophage in the "fatigue" of soils cropped to lucerne [trans. title], A. DEMOLON and A. DUNEZ (3. *Internatl. Cong. Soil Sci., Oxford, Eng., 1935, Trans., vol. 1, pp. 156, 157*).—The authors refer to the gradual loss of the vigor of the leguminous crop, accompanied by gradually increasing weed competition. Experiments here very briefly summarized led him to the conclusion that this failure is due to a bacteriophage specific for *Bacillus radicicola*. Reinoculation restored the normal growth of the legume crop.

Electrodialysis as a means of measuring fertility, J. V. CUTLER and I. DE V. MALHERBE (3. *Internatl. Cong. Soil Sci., Oxford, Eng., 1935, Trans., vol. 1, pp. 95-97*).—The authors report experiments with about 60 soils, samples of from 10 to 35 g having been electrodialyzed at an electromotive force of 150 v and a current of 0.2 a. Best agreement with the results of field trials and laboratory tests was obtained by measurements of the rate of outgo of the nutrient ions during the first stages of the electrodialysis. The authors also determined the total of nutrient ions removed during a complete electrodialysis, but state that "we feel that the rate of outgo is far more valuable as a criterion than the total removed in the case of K, Ca,  $P_2O_5$ , and the aggregate.

"Nitrate nitrogen determination was not as accurate as that of the other ions, the . . . removal of interfering bodies being at times very difficult . . . We found the method suitable within limits, and the figures give a clue to the content of the soil.

"By suitable adjustment of the conditions and period of electrodialysis it is possible to obtain removal equal to displacement by various strengths and bulks of displacing agents. This is of very considerable significance and opens up further lines of investigation."

Commercial fertilizers report for 1936, E. M. BAILEY (*Connecticut [New Haven] Sta. Bul. 390 (1936), pp. 59-IX*).—In connection with this presentation of the 1936 commercial fertilizer inspection analyses, organic materials as soil amendments are very briefly discussed. Analyses of some special and home mixtures and of manures and liming materials are also reported upon.

**Commercial fertilizers, 1936, E. R. TOBEY** (*Maine Sta. Off. Insp.* 161 (1936), pp. 71-118).—This report contains the analytical data obtained in the 1936 official analyses, including determinations of the magnesium content.

**Commercial fertilizers in 1935-36, G. S. FRAPS, S. E. ASBURY, and T. L. OGIER** (*Texas Sta. Bul.* 529 (1936), pp. 51).—This bulletin presents, for the 1935-36 season, the usual annual analyses, together with information on the local use of fertilizers and recommendations for various crops.

## AGRICULTURAL BOTANY

**Life and work of Cyrus Guernsey Pringle, H. B. DAVIS** (*Burlington: Univ. Vt., 1936, pp. [3]+756, [pls. 2, figs. 2]*).—This volume includes accounts of Pringle's early plant-breeding work and of his plant collecting in Vermont, the western United States, and finally in Mexico (*E. S. R.*, 25, p. 195). Information is included about Mexican plants and ecological data on the flora of Central America and Mexico gleaned from his diaries, correspondence, published papers, etc. The distribution lists of Mexican plants are from three herbariums (National, Gray, and Pringle).

**Groups of plants valuable for wildlife utilization and erosion control, W. L. MCATEE** (*U. S. Dept. Agr. Circ.* 412 (1936), pp. 12, pls. 7).—The author discusses and lists plants utilized by wildlife (cover plants, browse plants, herbage, mast producers, fruit producers, and seed producers) and those useful to wildlife that have been recommended also for erosion control, including crop and pasture plants and vines, shrubs, and trees.

**Tree ring width as an index of physiological dryness in New England, C. J. LYON** (*Ecology*, 17 (1936), No. 3, pp. 457-478, figs. 5).—"The annual rings of old hemlock trees (average age 279 yr.) have been carefully measured and graphs made from the mean values in order to show the fluctuations in radial growth rates from year to year. Cross-identification of individual trees within a forest and of groups of trees from several sites in Vermont and New Hampshire is entirely possible, due to dominance of the factor of physiological dryness within the area. Many years since 1600 are found to have been outstanding for the good moisture conditions available for plant growth. During the same three and a third centuries about twice as many years are marked by actual physiological drought which retarded plant growth throughout the entire area. Cyclic effects are not evident. In general, the standard weather records of an area fail to indicate the years with particularly favorable or unfavorable conditions for growth, while the hemlock tree, as used in this analysis, offers a better as well as much longer record of these conditions in its general locality."

**The accuracy of growth substance determination methods** [trans. title], I. JUEL (*Planta, Arch. Wiss. Bot.*, 25 (1936), No. 2, pp. 307-310).—The action of a standard solution of  $\beta$ -indolyl-acetic acid on oat coleoptiles was tested by means of the growth substance determination method used in København (Copenhagen), the fluctuations in size of curvature from day to day in two experimental series amounting to only about 35 percent.

**Growth hormones in plants, P. BOYSEN JENSEN**, trans. and rev. by G. S. AVEY, JR., and P. R. BURKHOLDER (*New York and London: McGraw-Hill Book Co., 1936, pp. XIV+268, figs. 64*).—This English translation (with the collaboration of H. B. Creighton and B. A. Scheer) of the German work previously noted (*E. S. R.*, 75, p. 185) has been "expanded to include 188 new contributions to the literature and 40 additional illustrations", and a summary at the end of each chapter and an index have been added. The arrangement of certain chapters has been modified to facilitate the familiarization of students with techniques and general methods of procedure, and the essential features of the "controver-

sial final chapter of the German edition have been included so far as possible in earlier chapters. . . . A selected list of titles dealing with the influence on plants of substances such as bios, folliculin, and other sex hormones, those affecting the growth of fungi, etc., has been added for the convenience of students interested in these topics. They are not discussed in the text."

**Studies of growth-promoting substances** [trans. title], H. DOLLFUS (*Planta, Arch. Wiss. Bot.*, 25 (1936), No. 1, pp. 1-21, figs. 8).—This is a thesis from the University of Rostock in which, using the diffusion procedure and the oat test, the author claims to have demonstrated for *Sorghum vulgare* that the upper 2 mm of the coleoptile are rich in growth hormone, the next 2 mm much less so, and that the remaining 4 mm, like the nodes and epicotyl, contain none. Decapitated maize seedlings with a rich supply of growth hormone show a gradual decrease in geotropic sensitivity in the coleoptile. When the decapitation is done up to or beyond the nodes, the presentation time is very much increased. Polarizability is still present but weak. In corresponding experiments with sorghum, the phototropic sensitivity of the first 2 mm drops rapidly, but with abundant growth hormone and light phototropic curvatures of the epicotyl stump can be obtained. It is thus polarizable by light. The growth hormone of pollinia causes root formation in epicotyl stumps. In leaves of *Podophyllum* the tip is the principal growth hormone center. The lamina, however, forms the hormone and conducts it basipetally in the vascular elements. In the onion seedlings the essential oil is toxic to growth, inhibiting the growth of coleoptiles. Here the growth hormone is conducted basipetally from the seedling tip. Ovaries and cupules of various plants are rich in growth hormone in the seed primordia. They furnish the growth hormones necessary for growth stretching in the pericarp or cupule.

**Inducement of fruit development by growth-promoting chemicals**, F. G. GUSTAFSON (*Natl. Acad. Sci. Proc.*, 22 (1936), No. 11, pp. 628-636, figs. 5).—Indole-3*n*-propionic acid, indolebutyric acid, indolenetic acid (heteroauxin), and phenylacetic acid in lanolin were applied to the stigma or to the cut style in flowers nearly ready to open. Tomato, snapdragon, salpiglossis, petunia, tobacco, *Agapanthus*, *Vallota*, *Zephyranthes*, begonia, Hubbard squash, crook-necked squash, cucumber, watermelon, eggplant, and pepper were used. All the chemicals stimulated enlargement of the ovaries beyond that met with in unpollinated and untreated flowers, and mature fruits, without seeds, were produced in tomato, petunia, salpiglossis, and pepper.

**The action of materials of oestrogenic nature on plant growth** [trans. title], K. NEHRING and H. MÖBIUS (*Ztschr. Pflanzenernähr., Düngung u. Bodenk.*, 44 (1936), No. 1-3, pp. 95-140, figs. 2).—A series of experiments were conducted to determine whether stable manure and liquid manure contain materials of oestrogenic nature which exhibit a specific action on plant growth, and whether in a certain measure the favorable effects of these manures may not be attributed to them. The results appeared to indicate only a general stimulatory action of the follicular hormones present. The view that these substances possess a special significance for the action of these manures is excluded, since in the tests described they were present in too small quantities for any such role.

**Preliminary observations on growth and phototropic response of oat seedlings**, E. KARRER (*Smithsn. Misc. Collect.*, 95 (1936), No. 9, pp. 4, fig. 1).—It is concluded from this preliminary study that the conditions for optimum growth and greater uniformity of phototropic response involve contact with nutrient solution, radiant energy of extended wavelengths (at least different wavelengths at different growth stages), a wave of temperature rather than constant temperature, perhaps darkness as well as light, and proper atmosphere.

**Growth of germ tubes of Erysiphe spores in deuterium oxide, R. PRATT** (*Amer. Jour. Bot.*, 23 (1936), No. 6, pp. 422-431, figs. 5).—In concentrations of  $D_2O$  of from 0.02 to 100 percent spore germination proceeded readily. Subsequent elongation was markedly inhibited by higher concentrations, which appeared to limit the amounts of solutes and colloids within the spores available for growth.

**Stimulation of root-hair growth in legumes by sterile secretions of nodule bacteria, H. G. THORNTON and H. NIOOL** (*Nature [London]*, 137 (1936), No. 3464, pp. 494, 495).—This note reports quantitative evidence of such stimulation in a study of the action of bacterial secretions on root-hair growth. Further data are needed before the active component of the secretions can be definitely related to other growth-stimulating substances, and before it can be determined whether the same substance also stimulates growth of cells within the root.

**The influence of individual mineral elements of the nutrient medium on the formation of acids by the fungus Aspergillus niger, II, V. S. BUTKEVICH (BUTKEVITSCH) and A. G. TIMOFEEVA** (*Mikrobiologiya*, 4 (1935), No. 4, pp. 489-494; *Eng. abs.*, p. 494).—In *A. niger* cultures with a relative nitrogen deficit, potassium and sodium nitrates proved a more efficient source of nitrogen for citric acid accumulation than did ammonium nitrate. Elimination of iron from the medium had no noticeable effect on the acid formation, but withholding zinc caused a considerable decrease in citric acid and a rise in gluconic acid. Limiting of the fungus development by a relative deficiency of phosphorus and sulfur but with abundant nitrogen gave an intensive citric acid accumulation, but the latter result did not occur when growth was limited by a potassium and magnesium deficit. A certain relative excess of these elements was a necessary condition for the formation and accumulation of acid.

**Occurrence and transport of a substance causing flowering in the soya bean (Glycine max L.), J. KUIJPER and L. K. WIERSUM** (*K. Akad. Wetensch. Amsterdam, Proc.*, 39 (1936), No. 9, pp. 1114-1122, figs. 3).—The results are given of experiments which convince the authors that a material carrier of some sort was transported over the graft union from flowering, short-day scions to long-day vegetative stocks and accelerated flowering in the latter.

**A growth-substance inactivator from Phaseolus seedlings [trans. title], P. LARSEN** (*Planta, Arch. Wiss. Bot.*, 25 (1936), No. 2, pp. 311-314).—A growth substance inactivator (probably destructive in its action) was isolated from wounded *Phaseolus* seedlings with agar and was found also in the press sap of nonwounded seedlings. It was at least partially thermolabile.

**Physiological studies on Rhizobium, VI, VII, D. W. THORNE and R. H. WALKER** (*Soil Sci.*, 42 (1936), Nos. 3, pp. 231-240, fig. 1; 4, pp. 301-310, figs. 2).—In continuation of this series of studies (*E. S. R.*, 76, p. 312) at the Iowa Experiment Station, the following two papers are presented:

**VI. Accessory factors.**—Small amounts of iron added to a nitrate-sucrose C. P. medium greatly increased the growth of *R. trifolii* and *R. meliloti*, the optimum concentration being about 10 p. p. m. Several *Rhizobium* species failed to maintain continuous growth in a mineral salts-sucrose C. P. medium with  $KNO_3$  as nitrogen source but were able to do so with  $NH_4Cl$  or asparagine. Reducing agents (e. g., cysteine or thioglycolic acid) increased the growth and oxygen utilization in media composed of highly purified materials. There was no evidence that these bacteria require any complex, unidentified substance for growth, but many materials stimulated their growth and respiration in the media above noted.

**VII. Some physiological effects of accessory growth factors.**—Measuring oxygen consumption and  $CO_2$  production in Warburg manometers, the following physiological effects were noted. Brown cane sugar, soil extract, *Asoto-*

*bacter vinelandii* medium extract, and cysteine added to  $\text{KNO}_3$  or  $\text{NH}_4\text{Cl}$  media lowered the respiratory quotient of *R. trifolii* for the first few hours, and yeast and alfalfa extracts did so for most of the active-growth period. Agar lowered the respiratory quotient of *R. meliloti* in a glucose-nitrate but not in a glucose-yeast extract medium.

Indications were obtained that the accessory substances studied reduce the oxidation-reduction potential of  $\text{KNO}_3$ -sucrose C. P. media. An important role of these substances appears to be that of an initial hydrogen donor. Its role in turn appears to be to lower the oxidation-reduction potential of the medium and to furnish a readily available initial source of energy, enabling the bacteria to make the necessary adjustments for establishment of favorable growth conditions.

**Studies of nitrogen translocation in the higher plants** [trans. title], H. FISCHER (*Ztschr. Bot.*, 30 (1936), No. 10, pp. 449-488).—The author presents an analytical and experimental review, including the significance of turgor in translocation, the independent translocation of nitrogen and carbohydrates, escape from cut-off leaves, and the effects of narcosis and oxygen deficiency. A bibliography of 70 titles is provided.

**The role of potassium and phosphorus in the assimilation of various forms of nitrogen by plants** [trans. title], T. W. TURTSCHIN (*Ztschr. Pflanzen-ernähr., Düngung u. Bodenk.*, 44 (1936), No. 1-3, pp. 65-83).—The action of potassium and phosphorus on nitrogen assimilation by plants is said to be connected with their influence on the course of the oxidation-reduction processes. Phosphorus furthers the reduction activity of the plant and thus influences the intake of nitrates. Potassium activates the oxidative processes and so exerts a positive influence on the primary synthesis of amides at the expense of ammoniacal nitrogen.

**Phosphorus nutrition of citrus and the beneficial effect of aluminum**, A. R. C. HAAS (*Soil Sci.*, 42 (1936), No. 3, pp. 187-201, pls. 2).—In this study by the California Citrus Experiment Station the use of calcium aluminate proved beneficial to both the roots and tops of lemon seedlings. In aerated culture solutions the beneficial effect of phosphate on lemon leafy-twigg cuttings was largely in the growth of the tops. With aluminum present the roots were healthy and more extensive, but the tops were usually retarded. Very little growth may occur in nonaerated cultures deficient in phosphorus, though the roots remain healthy. Aluminum greatly improved the root systems of Lisbon lemon leafy-twigg cuttings grown without phosphate, but when phosphate was present for a few days at intervals of several weeks aluminum benefited the roots at the apparent expense of the tops. Root caps were numerous with aluminum in the culture solution. Lateral buds inhibited by phosphate deficiency resumed growth when it was added. Extreme symptoms of such deficiency were accompanied by a low phosphorus content of the tissues. Aluminum proved beneficial to the early growth of Valencia orange leafy-twigg cuttings whether or not zinc was added to the culture solution. When aluminum containers were used for the cultures, the roots appeared healthy and were much shorter when 105 p. p. m. of phosphate were added continuously than when the phosphate was present for only a few days at intervals of several weeks.

**Substitutes for potassium in metabolism of the lowest fungi**, O. RAHN (*Jour. Bact.*, 32 (1936), No. 4, pp. 393-399).—This is a contribution by Cornell University.

*Aspergillus niger*, two species of *Saccharomyces*, various species of *Mycobacterium*, and all Gram-positive bacteria so far investigated require potassium

for growth. The only element capable of replacing K in yeast, mycobacteria, or aerobic sporeformers is rubidium, though the crops are smaller. The evidence regarding substitution by cesium is contradictory in *Aspergillus*, negative in the other organisms. Lithium or sodium cannot replace potassium, nor can the bivalent radioactive elements do this. Since rubidium is the only substitute, it seems that the radioactivity of potassium is an essential factor in its role, but not the only factor. The Gram-negative bacteria investigated so far, with the exception of *Rhizobium*, can grow without potassium. At least they develop to large numbers in media made from analyzed C. P. chemicals in glass containers, and addition of potassium salts does not greatly increase the crop. Gram-positive bacteria develop in such media only after addition of potassium salt."

**Relation between the pH of the culture substrate and the action at a distance of lead** [trans. title], C. SEMPLO (*Riv. Patol. Veg.*, 26 (1936), No. 7-8, pp. 279-297, figs. 11).—Studies of the effects of lead, acting at a distance, on the development of *Thielavia* (*Thielaviopsis*) *basicola* are reported.

**Cryptotrophic malnutrition of sorghum in solution culture**, K. A. GROSSENBACHER and B. E. LIVINGSTON (*Amer. Jour. Bot.*, 23 (1936), No. 9, pp. 588-591, figs. 2).—From the results of a 42-day series of solution cultures in the greenhouse, it appeared that of the 27 elements tested Mn, B, Zn, and Cu were all necessary for excellent growth of Black Amber sorghum under the general conditions. Apparent symptoms of malnutrition seemingly due to deficiency of Mn, B, Zn, and Cu are superficially described in terms of the appearance of the plants, dry weights of top and roots, and water content of top.

**Toxicity of mercury vapor to germinating tobacco seeds**, R. R. KINCAID (*Plant Physiol.*, 11 (1936), No. 3, pp. 654-656).—This study at the North Florida Substation indicates that toxicity varies directly with the area of mercury exposed, and that the area to which germinating tobacco seeds could be exposed under the experimental conditions without apparent injury was less than 0.07 cm<sup>2</sup> in 4 l of enclosed space, or 0.018 cm<sup>3</sup> per liter. Preliminary tests supported the theory that the toxicity of mercury varies directly with the temperature. "These observations suggest that caution must be exercised in the use of mercury devices, such as pumps, manometers, and seals in biological apparatus."

**The composition of the cell wall in plants, I** [trans. title], R. S. HILPERT (*Ber. Deut. Chem. Gesell.*, 69 (1936), No. 6, pp. 1509-1514).—Analyses are presented of the cell-wall material of the primary shoots of asparagus before emergence, of malted barley embryos, and of seedlings of oats, maize, wheat, and rye.

**The physiology of tannin in the plant cell, II** [trans. title], W. HAUSER (*Protoplasma*, 26 (1936), No. 3, pp. 413-417).—Continuing these studies (E. S. R., 75, p. 316), it is shown that in the system gelatin-water-alcohol tannin checks the separation into its component parts. Tannins, as phenols of large molecule, thus maintain the homogeneity of the plasma and they also exert a protective action against injurious influences, such as drying and frost.

**The structure of the non-starch-containing beet chloroplast**, E. WEIER (*Amer. Jour. Bot.*, 23 (1936), No. 10, pp. 645-652, figs. 2).—In this study at the Oregon State College, by the use of critical fixing, staining, and illuminating methods and comparing fresh material with specially prepared material, clear evidence was obtained that the chloroplast in starch-free cells of garden beet foliage consists of a colorless matrix in which small spherical granules are embedded. Observation in blue and red light indicated that the chlorophyll pigments were confined to these granules. In addition to chlorophyll, a Sudan

II-staining substance was found associated with the granules. A general review of present-day conceptions of chloroplast structure is included.

**The state of water in ducts and tracheids, G. J. PIERCE** (*Plant Physiol.*, 11 (1936), No. 3, pp. 623-628).—Carrying further his previous studies (E. S. R., 76, p. 168), the author discusses certain general phases of the problem as resulting from a consideration of his observations and experiments under climatic conditions of considerable variety, and then details the methods and records of the present study.

It is deemed clear from the evidence that in the mass of wet wood constituting a part of the vascular system of a living plant water may exist exclusively in liquid form, or part in liquid form and part as vapor. The liquid water may fill a duct or tracheid, it may be "bound" in the walls, it may be more or less free on the wall as a film, and it may fill as vapor the remainder of the space surrounded by the wet wall. "Transpiration from the surfaces, wherever they may be, of the continuous mass of water of which the living organism consists will set up, in the mass forces, tensions which will conform in place and power to the structure and composition of the system. The bound water of the walls of the vascular elements forms a water seal. . . Hence the traction is upward, not lateral. . . The maintenance of water as vapor, liquid film, and liquid mass in the vascular element and their walls, in the hydrostatic-pneumatic system of woody plants, is possible only when living cells are duly associated with the vascular tissues. . . The living cells are indispensable, not for moving but for conditioning the movement of water."

**Further notes on water and cane ripening, C. E. HARTT** (*Hawaii. Planters' Rec.* [*Hawaii. Sugar Planters' Sta.*], 40 (1936), No. 4, pp. 355-381, figs. 6).—Continuing these studies (E. S. R., 72, p. 308), using the variety H 109, the author found that although photosynthesis can take place in plants below the wilting point the process is more active with adequate water supply. Carbohydrate translocation was also more active under an adequate water supply, but storage was greater in plants deprived of water. The sugar in plants receiving water was more readily expressed than that in plants deprived of water.

After 48 hr. in darkness there was a decrease in the invertase activity in the leaf blades, but this enzyme was more responsive to changes in light or darkness under plentiful than under deficient water supply. Maltase in the blades was less sensitive to darkness than invertase. Withholding water resulted in an increase in invertase activity in the blades in darkness but a decrease in light, though its activity in the other plant organs seemed unaffected by the water supply. Withholding water induced a decrease in amylase and dextrinase activity in the blades. The plants having the most active invertase, amylase, and maltase in the blades had also the highest percentages of sucrose and polysaccharides in the blades. These enzymes of the leaf blades were sensitive to differences in moisture and light, but those in the sheaths were less so than those in the blades. The only enzyme in the green-leaf cane apparently affected by treatment was maltase, while in the dry-leaf cane any differences due to treatment were so small as to be considered insignificant.

**The fluctuations of sugars in the leaf sheaths of the sugar cane plant during the day and the night, C. E. HARTT** (*Hawaii. Planters' Rec.* [*Hawaii. Sugar Planters' Sta.*], 40 (1936), No. 4, pp. 329-354, figs. 6).—This paper considers the nature of translocation in the sugarcane plant, the location and time of its occurrence, the external and internal factors affecting the rate, and theories as to the mechanism. The results of analyses of moisture, simple sugars, cane sugar, starch, and total polysaccharides in the sheaths at hourly

or bihourly intervals during both day and night are given in graphic and tabular forms.

Both cane sugar and the simple sugars were found to be translocated, and transport occurred both by day and by night. The percentage of water proved an important factor in determining which form of sugar was transported the more predominantly in a given plant at a given time. The temporary storage of polysaccharides in the sheath during the night aided in the translocation of carbohydrates from the blade into the stem.

**The dependence of the respiratory intensity of organisms on the water content and colloidal state of the protoplasm** [trans. title], C. SCHLIEFER (*Biol. Zentbl.*, 56 (1936), No. 1-2, pp. 87-94, figs. 2).—This is a review of published works on the subject as pertaining to both plants and animals, including a literature list of 23 titles.

**Comparative study on the mechanism of the respiratory process of two closely related strains of *Rhizopus nigricans* in connection with the differentiation of the thallome and the changes of external conditions**, E. KANEL' (KANEL) (*Mikrobiologiča*, 4 (1935), No. 4, pp. 636-654; *Eng. abs.*, pp. 652-654).—The study reported was carried out in two parts: (1) Preliminary tests for study of the oxidation-reduction conditions created during growth and of the energy expenditure by the fungus under the usual cultural conditions, and (2) parallel tests with ordinary cultures and with submerged ones not showing the differentiation into upper and lower thallus surfaces.

**Influence of oxygen and carbon dioxide concentrations on the respiration of tomato fruits**, F. G. GUSTAFSON (*Amer. Jour. Bot.*, 23 (1936), No. 6, 441-445, figs. 8).—Reduction in respiration following decreased O<sub>2</sub> with increased CO<sub>2</sub> varied with the stage of fruit development. It retarded ripening without apparent injury.

**The influence of different kinds of light and radiation on the development of crop plants** [trans. title], J. VOSS (*Angew. Bot.*, 18 (1936), No. 1, pp. 43-75, figs. 15).—The author reports the results of tests of the suitability of the sodium vapor lamp, mercury high pressure lamps of different types, the neon tube, and mixed lights (mercury and incandescent lamps) as light sources for the growing of crop plants (peas, oats, and summer wheat) in the absence of daylight, and of the effects of ultraviolet light on the germination and development of wheat.

**The influence of radiation on light and dark seeds** [trans. title], D. MEISOEKE (*Jahrb. Wiss. Bot.*, 83 (1936), No. 3, pp. 359-405, figs. 27).—These studies were carried out on the seeds of five species of plants previously found to germinate best in the light and eight to germinate best in the dark. The tests were made with monochromatic light of wavelengths between 2,400 and 365 mμ, using various artificial light filters, simultaneous radiation with different spectral regions, light of different intensities, green leaves as light filters, and daylight.

**The measurement of the intensity and the colour of the light in woods by means of emission and rectifier photoelectric cells**, W. R. G. ATKINS, H. H. POOLE, and F. A. STANBURY (*Roy. Soc. [London], Proc., Ser. B*, 121 (1937), No. 824, pp. 427-450, figs. 6).—The optical conditions are considered, methods of measuring the photoelectric current in the field are described, and the wavelength sensitivity curves of the photoelectric cells used are plotted for a mean noon sunlight spectrum. For ecological work the illumination in shaded sites is considered best expressed as the "daylight factor", viz, the value of the vertical component of the illumination at any spot given as a percentage of the diffuse light in the open, which is nearly a constant.

In a wood consisting mainly of *Fagus sylvatica*, a number of sites examined showed daylight factors of from 2 to 5 percent. In such heavy shade the color factor was greatest for the deep red, and for green it was greater than for blue. There were indications of an absorption band in the near red. In such sites the radiation was about twice the daylight factor. It was found that whereas gray skylight showed an intensity maximum at 430 m $\mu$  light in heavy shade had its maximum at 760 m $\mu$ , with a minimum at 650 m $\mu$  and a secondary maximum at 550 m $\mu$ .

**The effect of temperature on translocation from leaves**, O. F. CURTIS and S. D. HEERY (*Amer. Jour. Bot.*, 23 (1936), No. 8, pp. 528-532).—In this work at Cornell University, chilling the petioles of bean leaves to between 0.5° and 4.5° C. greatly reduced but did not stop transport of carbohydrate from the leaves. At 7°-11° distinctly more translocation occurred, but less than at 17°-24°. A significant amount took place when entire plants were placed at 0°-2°.

**Gradients of freezing in foliage leaves** [trans. title], J. GICKLHORN (*Protoplasma*, 26 (1936), No. 1, pp. 90-96, figs. 2).—This is a study of the differences in cold resistance in different parts of the same leaf, in which the author used *Magnolia*, *Helianthus*, *Rhododendron*, *Hedera*, *Cydonia*, *Sambucus*, *Mahoberberis*, *Rosa*, and *Helodea*.

**Vernalization**, F. G. GREGORY and O. N. PUEVIS (*Nature* [London], 138 (1936), No. 3484, p. 249).—From experiments with excised cereal embryos it would appear that the "cause" of vernalization by low temperature lies entirely in the embryo.

**Treating with mordants of the spring wheat seed under condition of yarovization**, E. FOMIN and K. NOZDRACHOV (*Trudi Inst., Lab. Fitopat., Ukrain. N.-D. Inst. Zern. Gosp. (Bul. Inst., Dept. Phytopath., Ukrain. Sci. Res. Inst. Grain Cult.)*, No. 1 (1935), pp. 65-75; *Eng. abs.*, pp. 74, 75).—Spring wheat used for vernalization is said to undergo higher bunt infection than the nonvernalized seed. This is a progress report on the causes of this condition and on its control by seed treatments.

**Tuberization of artichokes regulated by capping stem tips with black cloth**, P. W. ZIMMERMAN and A. E. HITCHCOCK (*Contrib. Boyce Thompson Inst.*, 8 (1936), No. 4, pp. 311-315, fig. 1).—Potted artichokes (*Helianthus tuberosus*) were grown in summer in three lots: (1) Under normal day length, (2) entirely covered with black cloth from 4:30 p. m. to 9 a. m., and (3) with only stem tips capped with black cloth during the same hours. The first set developed long underground stems but no tubers. The other two sets developed tubers but no underground stems. Capping the stem tip, therefore, had the same effect as covering the whole plant to provide a shortened day, the controlling influence being centered in the growing tip, perhaps in the form of chemical regulators (hormones).

**A study on the formation and nitrogen content of root tubercles of cowpea**, M. L. DINGLASAN (*Philippine Agr.*, 25 (1936), No. 2, pp. 168-190, fig. 1).—The nitrogen-fixing bacteria in the nodules examined appeared to be of one type, but the nitrogen content varied greatly with the character of the soil. Cultivation, soil sterilization, and fertilization also appeared to influence somewhat the nodulation and nitrogen fixation. Ammonium sulfate alone or with potassium sulfate gave low yields of nodules and total nitrogen, while superphosphate and potassium sulfate (separately or together) gave an increase. The production of nodules and total nitrogen in the nodules did not depend on the apparent vigor of the plants.

**The sequence and climatic distribution of some plant acids**, J. B. MCNAB (*Amer. Jour. Bot.*, 23 (1936), No. 9, pp. 629-634).—These studies on the order

in time of occurrence of oxalic, succinic, malic, tartaric, and citric acids in plants, in which analyses of a large number of species were made, led to the opinion that these acids may be formed from each other. Succinic acid is, perhaps, the mother substance, tartaric acid possibly being formed from malic, with tartaric and citric as the end products of the series, the former being more common in the tropics, the latter in the temperate zone. It is held likely that oxalic acid may result from drastic oxidation of the other acids mentioned.

**Isolation of citric acid from potato tubers, J. D. GUTHRIE** (*Contrib. Boyce Thompson Inst.*, 8 (1936), No. 4, pp. 295, 296).—Citric acid, considered important in respiration, was isolated from potato tubers.

**Grass seedling anatomy: The first internode of *Avena* and *Triticum*, L. BOYD and G. S. AVERY, JR.** (*Bot. Gaz.*, 97 (1936), No. 4, pp. 765-779, figs. 6).—A detailed study of the anatomy of the seedling axes of *T. vulgare* and *A. sativa* provides evidence for the following interpretations:

"The coleoptile is the first leaf above the single cotyledon; its divergence from the axis marks the coleoptilar node. The first internode, whether short (*Triticum*) or long (*Avena*), extends from the cotyledonary to the coleoptilar node. It has intermediate root-stem structure with two main endarch collateral bundles and numerous more or less transitional strands. The old term 'mesocotyl' implies that the first internode is part of the cotyledon; this is not the case, and the term should be dropped from the literature. The hypocotyl which lies between the cotyledonary plate and the upper limit of primary root structure is so short as to be practically negligible. The vascular relationships of seedling organs are discussed in some detail. The evidence from this study does not support recent theories which would make the epiblast-bearing grasses dicotyledonous or the seedling structure of Gramineae an anomaly among monocotyledons."

**Bacterium-like amorphous patches associated with certain races of *Neurospora*, D. PEASE** (*Amer. Jour. Bot.*, 23 (1936), No. 9, pp. 612-618, pl. 1, figs. 3).—Studies are reported on unexplained patches of amorphous, granular material found in agar cultures of a certain race of *Neurospora* at low pH. It is also reported that in 1- or 2-day-old cultures the entire contents of the hyphae often moved "with unbelievable rapidity, not only passing through transverse septa but passing from one hypha into another through pores in the walls of the adjacent filaments."

## GENETICS

**Chromosome structure X: An X-ray experiment, B. R. NEBEL** (*Genetics*, 21 (1936), No. 5, pp. 605-614, figs. 3).—First removing all the buds containing stages later than diakinesis, flowering heads of *Tradescantia reflexa* plants were radiated, at the New York State Experiment Station, with 50, 200, 500, and 1,000 r-units obtained from a Coolidge tube. The effects of radiation were correlated with the amount of dosage, and it was observed that at low dosages the effect was confined almost completely to lesions of the chromatids, whereas at higher dosages there was an increasing number of other lesions. With low dosage the indications were that the chromosomes are split in two previous to synapsis, while at higher dosages the chromosomes apparently split into four parts. The author interprets the findings as follows: "Each chromosome is composed of two split chromatids (or four half-chromatids) at all stages of presynapsis. In normal material the two half-chromatids that constitute a given chromatid lie very close to one another and do not

react individually. (The process of crossing over in *Tradescantia* is a reaction between chromatids in which every two half-chromatids behave as a physiological and mechanical unit.)

"Under low dosage of X-rays half-chromatids are physiologically unable to show separate reactions.

"With higher dosage of radiation (200 r-units and more) the spatial and physiological order of the threads within a chromosome is upset. Chromatic reactions may be recorded which affect one of four (or three of four) threads differentially. It is also indicated that with higher dosage chromatic reactions at a certain level of the chromosome may spread, involving sister and even homologous loci.

"The differential effect of higher dosage is thus attributed to action upon the immediate environment of the chromatin, perhaps to heat or to a general interference with the normal metabolism of the nucleus which in turn changes the type of reaction of the chromatin."

**Chromosome behaviour in relation to genetics of Agave.**—I, Seven species of fibre Agave, L. R. DOUGHTY (*Jour. Genet.*, 33 (1936), No. 2, pp. 197-205, figs. 4).—The somatic chromosome complements of seven species and the meiotic behavior, in the pollen mother cell divisions, of five are described from studies at the East African Agricultural Research Station, Amani. A basic chromosome number of  $x=30$  is inferred. The species most widely cultivated for fiber production are autopolyploids, i. e., *A. sisalana* and *A. fourcroydes*  $=5x$ , and *A. cantala*  $3x$ .

Breeding experiments indicated that the species are genetically heterozygous; structural hybridity and chromosome differentiation was indicated in the meiotic behavior. A certain degree of relationship between species in the group Rigidæ, presumed from similarity in general characteristics and limited distribution, is supported by cytological and breeding evidence. The diploid species will cross with one another and with polyploid species. Sterility in certain species was shown to be partly functional and partly influenced by external conditions.

**Chlorophyll deficiencies in Pennisetum typhoides (Stapf. & Hubbard), the pearl millet,** G. N. R. AYYANGAR and P. V. HARIHARAN (*Madras Agr. Jour.*, 23 (1935), No. 10, pp. 394-397).—Chlorophyll deficiencies resulting in pale and albino seedlings were found in pearl millet (*P. typhoides*). The factor *C*, a simple dominant to *c*, produces chlorophyll, the seedlings being white and dying in its absence. *C* with *E*, a second factor, produces good green seedlings, while without *E* the plants are pale green and weak. *E*, a simple dominant to *e*, operates only when *C* is present.

**Cytological studies of monosomic and derivative types of Nicotiana tabacum,** H. P. OLMO (*Cytologia*, 7 (1936), No. 1-2, pp. 143-159, figs. 21).—The meiotic behavior of the univalent chromosome in monosomic ( $2n-1$ ) types of *N. tabacum purpurea* (E. S. R., 73, p. 596) is described from studies at the University of California. Indications were that its abnormal behavior may provide opportunity for new chromosomal rearrangements. Various types of aberrant plants appearing in the progenies of the monosomic types described include trisomics, triploids, and others having various structural rearrangements of the chromosomes. "Monosomism creates a condition of genetical unbalance that may serve as the source of numerical or structural chromosomal recombinations."

**The chromosome morphology, secondary association, and origin of cultivated rice,** H. K. NANDI (*Jour. Genet.*, 33 (1936), No. 2, pp. 315-336, pl. 1, figs. 29).—Chromosome numbers were determined at the University of London in 14 varieties of *Oryza sativa*. The apparent diploid number was  $2n=24$  in all

the forms, there being no variation in number. *O. officinalis*,  $2n=24$ , has larger chromosomes than *O. sativa*. *O. minuta*,  $2n=48$ , is an allo-octoploid species which probably originated by hybridization (*O. officinalis*  $\times$  *O. sativa*) followed by a chromosome doubling.

Detailed studies of *O. sativa* revealed 10 types of chromosomes which fall into 2 groups of 5 types each. Of these 10 types, 8 are present twice and 2 types are present 4 times, making a total of  $2n=24$  in the diploid complex. During the heterotypic prophase, two unequal pairs of chromosomes with terminal satellites remain attached to the nucleolus until the nucleolus disappears complete at prometaphase. Pairing at diakinesis was by chiasmata. As meiosis proceeds the total number of chiasmata decreases, but the proportion of total chiasmata that are terminal increases from diakinesis to metaphase. The 12 bivalent chromosomes at early diakinesis differ in size and shape, the longest pair showing 3 chiasmata and the smallest 1 chiasma. Secondary pairing occurs among the bivalents at metaphase I or univalents at metaphase II. The minimum number of groups of bivalents or univalents is 5, which is deemed the primary chromosome number in *Oryza*. Of these 5 groups when secondary pairing is at maximum, 2 are made of 3 and 3 of 2 bivalents or univalents each. *O. sativa* is therefore a secondary balanced polyploid. In the heterotypic and homotypic metaphase the groups of secondarily paired bivalents or univalents act as single bodies, and in most cases arrange themselves in agreement with the stable form of arrangement of the corresponding number of floating magnets.

"Somatic chromosome analysis, meiotic chromosome behavior, together with the published evidence from haploid rice indicate that *O. sativa* is a secondarily balanced allotetraploid which originated through hybridization between two different five-paired species in which two chromosomes were duplicated, probably due to meiotic irregularities in the hybrid. This followed by a subsequent doubling of the chromosomes attained the secondary balance of  $n=12$ , the present existing number in *O. sativa*."

**Inheritance of grain shattering in rice (*Oryza sativa*)**, K. RAMIAH and K. HANUMANTHA RAO (*Madras Agr. Jour.*, 24 (1936), No. 7, pp. 240-244).—Crosses between shattering and nonshattering types of rice did not reveal in  $F_2$  any simple inheritance, although the correlation between number of grains shed in  $F_2$  and in  $F_1$ ,  $r=0.48\pm0.023$ , suggested that but few factors were involved.

**The inheritance of red pericarp colour in rice (*Oryza sativa*)**, K. RAMIAH and C. RAJASEKHARA MUDALIAR (*Madras Agr. Jour.*, 23 (1935), No. 7, pp. 268, 269).—Crosses between red and white rice produced a 15:1 ratio of red to white in  $F_2$ , indicating that two factors were involved for color.

**Hybridization of Triticum and Agropyron, I, II** (*Canad. Jour. Res.*, 14 (1936), No. 5, Sect. C, pp. 190-202, pl. 1, figs. 6; pp. 203-214, pls. 2, figs. 2).—Two contributions are presented.

**I. Crossing results and description of the first generation hybrids**, J. M. ARMSTRONG.—Two species of tetraploid wheat ( $2n=28$ ), Vernal emmer and Mindum, and three hexaploid ( $2n=42$ ) wheats of *T. vulgare* were crossed with *A. glaucum* ( $2n=42$ ) and *A. elongatum* ( $2n=70$ ), with an average crossing success of 18 percent. The seed from tetraploid wheat  $\times$  *A. glaucum* was slightly plumper and germinated better than that from tetraploid wheat  $\times$  *A. elongatum*, whereas hexaploid wheat  $\times$  *A. elongatum* gave decidedly plumper and better germinating seed than hexaploid  $\times$  *A. glaucum*. When grown under greenhouse conditions the  $F_1$  hybrids proved self-sterile and perennial, with hybrid vigor strongly marked. The hybrids were, in general, intermediate in morphological characters, but resembling *Agropyron* somewhat more than wheat. This dominance, whole or partial, was more noticeable in the *A.*

*elongatum* than in the *A. glaucum* crosses. Dominance phenomena are discussed in relation to current theories.

II. *Cytology of the male parents and F<sub>1</sub> generation*, F. H. Peto.—Meiosis was studied in *A. glaucum*, *A. elongatum*, and in the F<sub>1</sub> of these species crossed on varieties of *T. dicoccum*, *T. durum*, and *T. vulgare*. In *A. glaucum* a large proportion of the chromosomes formed bivalents with occasional univalents and quadrivalents. *A. elongatum* was very unusual in that uni-, bi-, tri-, quadri-, sexa-, and octavalent configurations were observed. The *A. glaucum* × *Triticum* hybrids usually averaged 4.8–6.2 bivalents per nucleus, thus indicating partial homology between one set of chromosomes from each of the parents. In *A. elongatum* × *Triticum* hybrids, numerous multivalent configurations were observed, suggesting that auto- as well as allosyndesis had occurred. Approximately one set of chromosomes remained unpaired in one collection of Vernal emmer × *A. elongatum*, and approximately two sets remained unpaired in crosses between three varieties of *T. vulgare* and *A. elongatum*. Two crosses exhibited an abnormally small amount of pairing, an effect attributed to the reaction of genetic factors limiting prophase pairing.

Tentative conclusions were made on the origin and genetic constitution of *A. elongatum* from the pairing behavior of the chromosomes in this species and its hybrids. "It appears likely that *A. elongatum* arose through hybridization between hexaploid and tetraploid species of *Agropyron* with subsequent chromosome doubling."

Development of the male gametes of *Lilium*, D. C. COOPER (*Bot. Gaz.*, 98 (1936), No. 1, pp. 169–177, figs. 31).—Studies at the University of Wisconsin of the nuclei of the generative cells of *Lilium regale*, *L. auratum*, and *L. philippinense* showed the typical mitotic division with the production of two male gametes. The generative cell was divided by a cell plate and the two gametes were seen to be distinct, fully organized cells. A distinct spindle was observed, and three of the chromosomes had median or submedian fiber attachments and the others had subterminal attachments.

[Papers in animal genetics] (*Amer. Soc. Anim. Prod. Proc.*, 1935, pp. 209–214, 217–237, fig. 1).—The following papers were briefly presented before the genetics section of this society: Some Developments in Overshot and Under-shot Jaw Studies in Sheep, by J. E. Nordby (pp. 209–211); The Dairy Cow in the Tropics, by A. O. Rhoad (pp. 212–214); The Role of the Gonad-stimulating Hormones in Reproduction, by H. R. Catchpole (pp. 217–222); The Physiology of Spermatozoa, by R. W. Phillips (pp. 222–235); and Some Practical Applications of Endocrinology to Animal Husbandry, by S. A. Asdell (pp. 235–237).

The inheritance of white facial markings in Arabian horses, C. T. BLUNN and C. E. HOWELL (*Jour. Heredity*, 27 (1936), No. 8, pp. 293–299, fig. 1).—The California Experiment Station has studied the facial markings in 477 Arabian horses. The markings have been designated as star, strip, snip, and chin spot, depending upon the part of the face involved. The results obtained in two series of matings give strong evidence that these characters do not compose an allelomorphic series. Each pattern seems to be conditioned by modifying factors of a general factor for white markings. The star, strip, and snip patterns apparently are inherited as dominant characters, while chin spot appears to be recessive.

A new lethal factor in the horse, R. PRAWOCHENSKI (*Jour. Heredity*, 27 (1936), No. 11, pp. 410–414, figs. 3; *abs. in Nature [London]*, 137 (1936), No. 3473, p. 869).—A three-fourths Arabian stallion produced 26 foals, of which 8 showed lameness as foals and had one or both forelegs defective with typically crooked immobile phalanges and were unable to stand. Because of the frequent occur-

rence of the abnormality and failure to locate common ancestors of the stallion and the mares producing the deformed foals, it is assumed that the condition is not due to a simple recessive gene. Suggestion is made that it might be a gene deficiency which behaves as a dominant to the normal.

**Small-animal breeding** (*U. S. Dept. Agr., Bur. Animal Indus. Rpt., 1936, p. 7*).—Results are briefly presented on the inbreeding experiments with guinea pigs and histological studies of the hypophysis from these strains, together with inbreeding experiments with rabbits.

**The trichogenic action of the sulfhydryl group in hereditary hypotrichosis of the rat**, G. J. MARTIN and R. E. GARDNER (*Jour. Biol. Chem., 111 (1935), No. 1, pp. 193-196, fig. 1*).—The test animals used in this study were from a strain of hairless rats in which it had been demonstrated that the hypotrichosis was due to a single recessive factor. Three groups of these rats received a daily allowance of glutathione, cystine, and cysteine, respectively, as supplements to their basal diet. The glutathione gave no response. The cystine stimulated hair growth, but this was shed in a short time and no further hairy growth occurred, while the cysteine stimulated growth of a complete hair coat which was maintained throughout the balance of the trial. From these results it is concluded that cysteine through the sulfhydryl group stimulated the hair follicle, resulting in a trichogenic action in hereditary hypotrichosis of the rat.

**[Poultry breeding and physiological investigations]** (*U. S. Dept. Agr., Bur. Animal Indus. Rpt., 1936, pp. 18, 19*).—Results are briefly presented on the sex-linked recessive gene for dark pigmentation in White Silkies; artificial insemination of turkey eggs with sperm from purebred and cross-bred chickens; prolactin content of the pituitaries of laying hens of different strains; relationship of hardiness to abnormal incubation temperatures and genetic constitution; successful artificial insemination of hens with 0.1 cc of mixed semen from several cockerels on alternate days; unfavorable effect of tremulous air cells on hatchability; and relationship of season of the year, growth of the bird, and individual characteristics of the hen to percentage of thick albumen in eggs.

**Studies on the inheritance of persistency**, F. A. HAYS (*Genetics, 21 (1936), No. 5, pp. 519-524, figs. 5*).—In an experiment at the Massachusetts Experiment Station, high and low persistency lines of Rhode Island Reds were crossed. The  $F_1$  generation showed a wide scatter in frequency distribution with regard to persistency, although there was evidence of the dominance of high persistency. The  $F_2$  generation showed a typical bimodal distribution for length of biological year with modes at about 200 and 350 days, with a dividing line between the two populations at about 270 days. From backcrosses and reciprocal crosses data were obtained indicating that high persistency depends in inheritance upon a single dominant autosomal gene. It is suggested that in selecting breeding stock for high persistency the standard be placed well above a 270-day minimum because of overlapping in phenotypes.

**Sexual dimorphism in Single Comb Rhode Island Red down color**, T. C. BYERLY and J. P. QUINN (*Jour. Heredity, 27 (1936), No. 8, pp. 319-322, fig. 1*).—In this study at the U. S. D. A. Bureau of Animal Industry, 1,102 Single Comb Rhode Island Red chicks and fully developed embryos were examined for evidence of black spotting or striping on the head. Of the total number examined 524, or 47.5 percent, had some black down on the head. A classification of the population with regard to sex showed that 84.9 percent of the spotted or striped chicks were females and 77.8 percent of the normal or nonspotted chicks were males. On this basis sex could be distinguished by color markings in 81.2 percent of the chicks examined. Examination of 663 chicks in another standard bred Rhode Island Red flock showed 42.1 percent to be spotted or striped, indicating that these characters are widely distributed among this breed.

[Studies in physiology of reproduction in animals at the Missouri Station] (*Missouri Sta. Bul.* 370 (1936), pp. 17-19).—Brief results are given on investigations of the occurrence of ovulation in the ewe, by F. F. McKenzie and C. E. Terrill; cytological changes in the anterior lobe of the pituitary in ewes during the oestrous cycle, and cytological study of the pineal body of the ewe, both by McKenzie and V. Warbritton; the discovery of a small gland in the pineal body of a sheep, by Warbritton; the afterbirth as an index to the thrift of the lamb, by McKenzie and R. Bogart; the induction of oestrus in a senile mare by the administration of serum from a pregnant mare, by McKenzie, Terrill, and L. R. Richardson; seasonal variations in libido and fertility of rams and the influence of feeding, by McKenzie, V. Berliner, and M. E. Vaughan; and stimulation of sperm production in a young sterile bull by the administration of Antuitrin S (a human pregnancy urine preparation), by McKenzie and Berliner, and pregnancy mare serum, by McKenzie and Terrill.

A study of the chromosomic elements of the follicular epithelium of the ovaries of birds [trans. title], J. HOMEDES I RANQUINI and J. MARTIN DE FRUTOS (*Arxius [Barcelona]*, n. ser., 2 (1936), No. 2, pp. 305-316, figs. 7; *Eng. abs.*, p. 316).—This report deals with hen and pigeon ovaries at different stages of ovulation. An abnormal behavior of the chromosomes was observed in some of the mitotically reproduced epithelial cells. In these cases the chromosomes are much shorter and thicker than normal, and the chromosome number is always inferior to the diploid, being generally nearer the haploid. The numerical variations observed ranged from 33 to 44 chromosomes in the hen and from 32 to 42 chromosomes in the pigeon. It is believed that these originate as a consequence of an increase or decrease of microchromosomes, with evidence that such anomalies are brought about by a mechanism of mitotic type.

It is suggested that such deviation from the typical condition may be the result of an impregnation of the cells by the oestrogenic hormone, causing a mitotic stimulus of pathological type.

Survival of deciduomata in the unilaterally pregnant rat, R. A. LYON and W. M. ALLEN (*Anat. Rec.*, 65 (1936), No. 3, pp. 351-356, figs. 4).—In a histological study of the genital tract of unilaterally castrated pregnant rats made from the eighth to the twentieth day of gestation, it is shown that the deciduomata in the sterile horn undergoes progressive degeneration, usually beginning on the tenth to twelfth day. By the twentieth day there was only scant evidence of the preexisting deciduomata. This indicates that the fetal part of the placenta, by its attachment to the endometrium, plays some role in the maintenance of the decidua.

On the relation between the site of injection of androsterone and the comb response in the fowl, A. W. GREENWOOD and J. S. S. BLYTH (*Quart. Jour. Expt. Physiol.*, 25 (1935), No. 3, pp. 267-277, figs. 2).—This report from the University of Edinburgh shows that the injection of a total of 2 mg of androsterone (divided into five daily doses) directly into the comb of capons produced a greater response in increasing the size of the comb than was obtained from the same dose injected intramuscularly in the pectoral region.

In further tests injections of the hormone into the comb of normal hens caused an increase in comb size, although less than that obtained in capons, while intramuscular injections were ineffective. Intracomb injections into a normal male showed no reaction, while an incompletely castrated male gave a marked response.

Effects of oestrin injections on accessory reproductive organs of the male ground squirrel (*Citellus tridecemlineatus*), L. J. WELLS (*Anat. Rec.*, 64 (1936), No. 4, pp. 475-497, pls. 3).—Injections of oestrin into both normal and castrated males during the season of low sexual activity resulted in gross hyper-

trophy of all accessory sexual organs. The response of such injections gave morphological evidence of the apparent transformation of connective tissue elements into epithelial-like cells, particularly in the secretory tubules of the prostate gland and to a lesser extent in the bulbar gland, Cowper's gland, Cowper's ducts, and prostatic ducts. An increase in connective tissue and smooth muscle was also observed in the seminal vesicles, epididymis, and ductus deferens. In contrast, oestrin injections during the breeding season, and consequently acting on the accessories that were simultaneously affected by large quantities of male hormone, resulted in a decrease in size and great damage to all accessory organs.

**Studies on the gonad-hypophyseal complex in estrin-injected rats,** S. R. HALPERN and F. E. D'AMOUR (*Amer. Jour. Physiol.*, 115 (1936), No. 1, pp. 229-238, figs. 4).—Two groups of mature rats each, including normal males, normal females, and ovariectomized females, were given daily injections of oestrin for 4- and 8-week periods, respectively. During the period of investigation the gonads showed a progressive loss in weight and progressive degeneration of the germinal elements, the effect being most pronounced in males. Eight weeks' injection gave a degree of degeneration comparable to that occurring after complete hypophysectomy. The mammary gland underwent extensive proliferation and contained secretion, and the hypophysis increased in weight from about 100 to 200 percent during a period of oestrin administration. It is suggested that oestrin stimulates the release of the gonadotropic hormone in normal animals.

**Effects of two hypophyseal gonadotropic hormones on the reproductive system of the male rat,** R. O. GREEP, H. L. FEVOLD, and F. L. HISAW (*Anat. Rec.*, 65 (1936), No. 3, pp. 261-271, pl. 1).—In further studies on the gonadotropic hormones of the pituitary (E. S. R., 75, p. 613), the effects of the follicle-stimulating and the luteinizing hormones when injected alone or in combination on the gonads and secondary sexual structures of normal and hypophysectomized immature male rats has been determined.

The follicle-stimulating hormone stimulated rapid proliferation of the germinal epithelium but did not affect the interstitial cells or accessory sex organs. The luteinizing hormone caused a marked development of interstitial cells, invariably followed by enlargement of the accessory organs, but did not hasten proliferation of the germinal epithelium. When the two were injected simultaneously both the tubules and the interstitial cells were stimulated, and the accessory organs were much larger than would be produced by a like amount of the luteinizing hormone acting alone. The fact that these hormones have just as definite and as dissimilar effects on the male gonads as on the female gonads indicates that the active principle in each is not sex specific in its activity.

**The gonad-stimulating activity of pituitary glands from horses of different ages and sex types,** A. A. HELLBAUM (*Anat. Rec.*, 63 (1935), No. 2, pp. 147-157, figs. 6).—With further reference to the gonadotropic activity of the pituitaries of horses (E. S. R., 70, p. 34), the gonad-stimulating ability of the pituitaries from young, old, and pregnant mares, geldings, stallions, colts, and fetuses has been assayed. Pituitaries from young nonpregnant mares and young geldings caused marked luteinization, whereas those from old mares and old geldings produced primary follicles. In each of these cases the size of the ovary exceeded the average produced by the composite hypophyseal powder used as a check. Pituitaries from stallions gave follicular development, but the ovary attained only about one-fourth the size of that from geldings. Extracts from colts and fetuses induced both follicles and corpora, although the ovaries were comparatively small. Results from pregnant mares were extremely variable depending upon the stage of gestation.

**The effect on the chick of some gonadotropic hormones,** W. R. BRENEMAN (*Anat. Rec.*, 64 (1936), No. 2, pp. 211-220).—This contribution describes a series

of tests in which various gonadotropic hormones were administered to young chicks and their effects on gonad development noted. The follicle-stimulating hormones (pig) and pregnant mare serum stimulated maximum gonad development in both males and females. The luteinizing hormone and tannic acid preparations of pregnancy urine caused marked weight increases in both testes and ovaries, the response to each being similar. Prolactin did not significantly decrease gonad weights in either sex, and in a few cases there was evidence of stimulation. The stimulating action of the follicle-stimulating hormone is partially inhibited by admixture with any of the other extracts used in this series. It is evident that the chick ovary at from 5 to 15 days of age is readily susceptible to stimulation.

The follicular apparatus of the ovary of the hypophysectomized immature rat and the effects of hypophyseal gonadotropic hormones on it, C. E. LANE and R. O. GREEP (*Anat. Rec.*, 63 (1935), No. 2, pp. 139-146, fig. 1).—Continuing this line of investigation (E. S. R., 74, p. 326), immature female rats hypophysectomized at 28 days of age were killed in groups of three at periods ranging from 1 to 38 days postoperation. Increased ovarian activity was noted to the fourth day after operation, followed by a gradual and uniform degeneration of the ovaries over the remainder of the period, as indicated by a decreased weight of the ovary and also a decrease in number of both primary and vesicular follicles. The fourth-day peak is attributed to pituitary materials forced into circulation while removing the gland. Injections of the follicle-stimulating hormone resulted in an increase in total follicle count but a decrease in vesicular percentage, whereas injection of the luteinizing hormone did not affect the total follicle count but markedly increased the percentage of vesicular follicles.

The effect of progestin on the *in vitro* response of the rabbit's uterus to pituitrin, A. W. MAKEPEACE, G. W. CORNER, and W. M. ALLEN (*Amer. Jour. Physiol.*, 115 (1936), No. 2, pp. 376-385, figs. 8).—Results obtained in these *in vitro* experiments indicate that the addition to the medium of progesterone, either in natural form as extracted from pig ovaries or the synthetic product prepared from stigmasterol, results in inhibition of the reaction of the rabbit uterus to pituitrin. Since the degree of progestational proliferation of the endometrium is generally accepted as a means of assaying for progesterone potency, it appears that endometrial proliferation and pituitrin desensitization are both physiological properties of progesterone.

The effect of gonadectomy on body structure and body weight in albino rats, H. HOLT, R. W. KEETON, and B. VENNESLAND (*Amer. Jour. Physiol.*, 114 (1936), No. 3, pp. 515-525, figs. 3).—Comparing the growth rates of normal and gonadectomized albino rats, it is shown that spayed females gained and maintained greater weight than the normal controls. This more rapid development was characterized by increase in skeletal growth and a general increase in size rather than by any increase in deposition of fat. Gonadectomy in the female apparently favorably influences the growth process, presumably through the growth hormone of the anterior lobe of the hypophysis. In males, variations in weight between normal and castrated individuals were neither predictable nor significant.

Effect of ovarian transplants upon the development and maintenance of the seminal vesicle and prostate gland of the albino rat, C. A. PFEIFFER (*Anat. Rec.*, 65 (1936), No. 2, pp. 213-237, figs. 12).—In cases of male rats castrated at birth and receiving ovarian transplants either at birth or at puberty, the smooth muscle of the seminal vesicles is hypertrophied in such a manner that it resembles that of the uterus in cross section. There is also a tendency toward a stratified squamous epithelium. The coagulation gland shows

a stimulation of smooth muscle and the formation of stratified squamous epithelium, which in extreme cases becomes cornified and undergoes all the changes of the vaginal epithelium during oestrus. The prostate gland is hypertrophied and also shows evidence of metaplasia. Both follicles and corpora lutea are produced in the ovarian graft. When the animals are castrated at puberty and ovarian grafts made at the same time, the only observed effect of the transplant is an increase in the smooth muscle of the seminal vesicles. In this case only follicles are produced in the ovarian tissue, as is true with transplants in a normal male.

The experimental induction of oestrus (sexual receptivity) in the normal and ovariectomized guinea pig, E. W. DEMPSEY, R. HERTZ, and W. C. YOUNG (*Amer. Jour. Physiol.*, 116 (1936), No. 1, pp. 201-209).—In this experiment various gonadotropic hormones were used singly and in combination in an attempt to experimentally induce oestrus in guinea pigs. Injections of theelin alone were followed by sexual receptivity in 31 percent of the spayed females and only 14 percent of the normal females. Divided injections of small quantities were not more effective than a single injection of a large quantity. Injections of the luteinizing hormone into normal females on the twelfth to fifteenth days of dioestrus produced heat in a large number of cases, but were ineffective when injected earlier in the cycle. Similar injections of the luteinizing hormone singly and in combination with oestrin were ineffective in spayed females. Injections of small doses of oestrin followed from 36 to 48 hr. later by injections of progesterone invariably produced heat in the spayed females. These results led to the postulation that in the guinea pig, after conditioning with oestrin, oestrus is caused by the action of progesterone produced from the ripening follicles under the influence of the luteinizing hormone.

[Studies on the physiology of lactation at the Missouri Station] (*Missouri Sta. Bul.* 370 (1936), pp. 36-42).—Brief reports are given on the artificial initiation of lactation and its continuance in female and male rabbits by suckling young, by C. W. Turner and A. J. Bergman; the further purification of the lactogenic hormone, galactin, and the response of the common pigeon to different injections of the lactogenic hormone, both by Turner and H. McShan; the failure to extract lactogenic hormone from bovine urine, by Turner and R. P. Reece; the inhibition of subsequent growth of mammary glands of immature rabbits by irradiation, by Turner and E. T. Gomez; the normal development of the udder of the goat, by Turner, Gomez, and E. P. Reineke; the failure of ovariectomy to influence lactation in the albino rat, and the apparent absence of lactogenic hormone in pituitaries of turkeys, geese, and ducks, both by Turner and Gomez.

The sterility in rabbits produced by injections of oestrone and related compounds, G. PINCUS and R. E. KIRSCH (*Amer. Jour. Physiol.*, 115 (1936), No. 1, pp. 219-228, fig. 1).—Rabbits were found to be most susceptible to oestrone sterilization on the third to fourth day postcoitum, injections of 150 rat units of oestrone in oil at this period resulting in complete prevention of implantation of the embryos. Injections of 200 rat units on the fifth to sixth days postcoitum resulted in only partial prevention of implantation as did less than 150 units on the third to fourth days. Injections of large amounts of oestrone both before and during cleavage did not affect the normal cleavage rate, and ova cultivated in vitro with oestrone in the medium go through cleavage at the normal rate. Oestriol is about one-fourth to one-fifth as effective as oestrone in preventing implantation, while dihydro-oestrone is approximately three times as effective as oestrone in this respect.

Is voluntary sex determination in the hen possible through sex hormones? [trans. title], F. ØKLAND (*Biol. Zentbl.*, 56 (1936), No. 3-4, pp.

147-150).—In this experiment an attempt to control the sex in chicks by administering varying doses of the female sex hormone "ovifollin" to hens gave completely negative results.

**The identification of the sex of beavers, F. W. YOUNG** (*Michigan Sta. Spec. Bul.* 279 (1936), pp. 8, figs. 6).—Determination of the sex of beavers is described based first on properly restraining the animal in a 10-in. pipe and then by visual examination or by palpation in the urino-genital orifice.

## FIELD CROPS

[Crops research of the U. S. Department of Agriculture, 1936] (*U. S. Dept. Agr., Sec. Agr. Rpt., 1936, pp. 87-93*).—Outstanding results are reported from improvement research with cotton, wheat, oats, corn, sorghum, and lettuce; study of soil moisture in relation to wheat production in the central Great Plains; experiments on chlorosis of rice due to deficiency of iron; ecological studies to determine effects of heat and drought on native grasses in the Great Plains; pasture experiments with woolly fingergrass in comparison with other grasses; fertilizer placement tests with cotton and tobacco; and reinforcement of cotton fertilizers with magnesium and calcium neutralizing agents. Much of the work was in cooperation with State experiment stations.

[Research with field crops in the Bureau of Plant Industry] (*U. S. Dept. Agr., Bur. Plant Indus. Rpt., 1936, pp. 2, 3, 4, 5, 6, 7, 8, 11, 12, 14, 15, 16, 17, 18*).—The progress and accomplishments are reported on briefly from agronomic investigations, including breeding work with corn, wheat, oats, barley, grain sorghum, rice, cotton, sugarcane, sugar beets, potatoes, alfalfa, crotalaria, and tobacco; cultural (including planting) tests with oats, potatoes, and sweet-potatoes; tests of the value of *Lespedeza sericea* for different purposes, of the adaptation of a new early lespedeza (No. 19604), and of woolly fingergrass; effects of heat and drought on native grasses in the Great Plains; fertilizer work, including placement experiments, with cotton, potatoes, and tobacco; fertilizers reinforced with magnesium and calcium for cotton and high nitrogen fertilizer mixtures for sugarcane; improved methods of ginning long-staple cotton; community production of cotton; extension of production of sugar beet seed; study of soil moisture in relation to wheat production in the central Great Plains; maintenance of soil productivity in irrigated regions by manure and pastured alfalfa in the rotation; irrigation water requirements of important field crops; study of germination of seed stored under various temperature and moisture conditions; and control of bindweed. Many studies were in cooperation with State experiment stations.

[Agronomic research in Arkansas], M. NELSON, C. K. McCLELLAND, L. C. KAPP, L. M. HUMPHREY, B. P. JOHNSON, J. R. COOPER, and V. M. WATTS (*Arkansas Sta. Bul.* 337 (1936), pp. 13-26, 29-37, 53, 54).—Progress results are reported from experiments with field crops (*E. S. R.*, 74, p. 771) at the station and substations, including variety trials with cotton, corn, wheat, winter and spring oats, barley, rice, grain sorghum, and soybeans and cowpeas for seed and hay; breeding work with cotton; fertilizer trials with cotton, rice, potatoes, and sweetpotatoes; use of lime; winter hardiness experiments with oats; cultural (including planting) tests with corn, oats, rice, and soybeans; effects of various treatments on duration of alfalfa stands; residual effects of winter cover crops sown in cotton middles on subsequent cotton yields; interplanting of legumes in corn and effects on yields of the succeeding crop of oats and cotton; control of rice weeds; rice yields following corn, cotton, and soybeans and response of these crops to irrigation; effect of fertilizers on yield and growth of rice; cover crops for rice; toxic effects of iron and manganese on

rice grown in nutrient solutions; cotton fiber investigations, including the development of a method of sorting fibers as to length by a photoelectric cell, and quality of fiber of pure lines of cotton; study of methods of manufacturing sorgo sirup; and pasture studies. The cotton fertilizer studies dealt with different formulas, rates of application, placement, home v. factory mixed, side dressing, and nitrogen carriers.

[Field crops work in Delaware], G. L. SCHUSTER and C. E. PHILLIPS (*Delaware Sta. Bul.* 203 (1936), pp. 13, 14).—Fertilizer and breeding experiments with wheat and trials of soybean introductions are reviewed briefly.

[Field crops work in Michigan] (*Michigan Sta. [Bien.] Rpt.* 1935-36, pp. 31-33).—Brief accounts of agronomic research not noted earlier report on the production of better alfalfa hay and avoidance of winter injury by timely cutting and improvement of old stands with grass; good pasture from alfalfa-brome-grass mixture; Sudan grass seed production; increasing sugar beet yields by transplanting; tests of promising new potato seedlings; plowing sweetclover under early for beans; and comparisons of colored bean types.

[Field crops experiments in Missouri], C. W. MCINTYRE, L. J. STADLER, G. F. SPRAGUE, B. M. KING, W. C. ETHERIDGE, E. M. BROWN, and J. M. POEHLMAN (*Missouri Sta. Bul.* 370 (1936), pp. 50, 55-61).—Progress results (E. S. R., 75, p. 36) are reported from breeding work with corn, wheat, oats for immunity or resistance to smuts, barley, and soybeans; genetic studies with corn; experiments on the production of genetic variations by radiation of pollen with ultra-violet rays and on the mechanism of gene rearrangement induced by X-ray treatment; variety trials with wheat, barley, soybeans, oats, and cotton; tests of strains of English grasses selected for leafiness; and comparisons of grazing systems and fertilizer tests with pasture. Certain lines of work were in cooperation with the U. S. Department of Agriculture.

[Agronomic work in Montana] (*Montana Sta. Rpt.* 1935, pp. 26-28, 36-41, fig. 1).—Agronomic activities related to the livestock industry in Montana, reviewed briefly, included the regrassing of abandoned land; variety tests of barley, oats, spring wheat, and rye for feed grain on irrigated and dry land; trials of wheat and oats for hay; tests of the merits of Ladak alfalfa; determination of good grass mixture, the merits of proper irrigation and grazing, and the value of manuring irrigated pasture; and growing and using crested wheat-grass for pasture and production of its seed under irrigation. Several lines of work were in cooperation with the U. S. Department of Agriculture.

The influence of temperature and available nitrogen supply on the growth of pasture in the spring, G. E. BLACKMAN (*Jour. Agr. Sci. [England]*, 26 (1936), No. 4, pp. 620-647, figs. 9).—Studying the principal factors controlling the growth of pasture in the spring, the author found that below a soil temperature at 4 in. of approximately 42° F. no growth took place. Between 42° and 47° nitrogen-manured pasture grew at a greater rate than the control, but at higher temperatures the growth rates were very similar. The manured herbage reached the grazing stage sooner than did the control. Nitrogenous fertilizers brought about marked changes in the nitrogen content of the herbage.

Below 42° temperature is the factor controlling growth. The greatest response to nitrogenous manuring may be expected when the soil temperature rises slowly from 42° to 47°, and conversely the smallest response when the rise between these temperatures is rapid.

Changes in the proportions of the components of seeded and harvested cereal mixtures in abnormal seasons, K. H. W. KLAGES (*Jour. Amer. Soc. Agron.*, 28 (1936), No. 11, pp. 935-940, figs. 2).—Mixtures of Marquis, Ceres, and Reward hard red spring wheat with Mindum durum and of Richland oats

with Odessa barley, compounded at the South Dakota Experiment Station in proportions ranging from 1 to 99 percent, were grown in 1935 in comparison with pure stands of the several varieties. Exceptionally large increases in the durum components of durum-hard red spring wheat mixtures were observed, and the barley components of various combinations of oats and barley increased materially over the percentage of barley planted. These changes in mixture components, exceeding expectations, were explained by the particular growing conditions and by the occurrence of one of the severest stem rust epidemics on record in the northern portion of the Great Plains area.

The relation of reserves to cold resistance in alfalfa, J. J. MARK (*Iowa Sta. Res. Bul.* 208 (1936), pp. 301-335, figs. 14).—To obtain more quantitative data on the relation of reserve levels to winter hardiness in alfalfa and to determine the type of differentiation reactions stimulated by high sugar levels and considered as actually responsible for cold resistance, experiments were made with Grimm alfalfa, fall clipped to induce varying reserve levels and also with varieties of known cold resistance.

The cutting of Grimm alfalfa in late August and early October prevented normal fall accumulation of reserve proteins and carbohydrates and resulted in complete winter-killing of plants during the winter of 1934-35. Roots of plants not cut after August 29 were 75 percent larger than those cut a second time on October 8. The roots of early cut plants also contained about 30 percent more carbohydrate and nitrogenous reserves on a green weight basis. The percentage of both soluble and insoluble nitrogen was higher in uncut than in cut plants throughout the test. No evidence that protein splitting was a factor in cold resistance was obtained.

Reducing sugars constituted a progressively smaller portion of the root reserves as fall advanced, while nonreducing sugars (sucrose) increased during the fall and were constant during winter with a slight increase toward spring. Starch began to disappear in early fall and constituted a very small portion of the root reserves in any variety after October. Digestion was most rapid in the hardy varieties. Analyses for starch in the spring showed no tendency toward reconversion of sugar to starch.

Analytical data provided no criteria by which the varieties could be ranked in order of hardiness as exhibited in field tests. Nonhardy varieties consistently exceeded the hardier ones in certain reserve fractions, whereas hardy varieties did not significantly surpass the nonhardy groups in any reserve fraction. The pectin and water-soluble gum fractions showed fluctuations among varieties that would not currently justify their use as indexes of hardiness of varieties.

The positive correlation between reserves and hardiness within a variety (Grimm) and lack of correlation when comparing varieties is considered to support the protoplasm differentiation hypothesis of winter hardiness. This assumes as prerequisites to the development of winter hardiness both an available reserve and a genetic ability to use these reserves in building a stable protoplasm.

Barley varietal trials at East Lansing, J. W. THAYER, JR., and H. C. RATHER (*Michigan Sta. Quart. Bul.*, 19 (1936), No. 2, pp. 97-100, figs. 2).—Wisconsin No. 38 and Spartan barleys, both smooth awned, have been outstanding in station tests. Wisconsin No. 38 is the best commercially available barley for sale for malt and also the highest yielder, whereas Spartan finds its place as a pearling and feed barley. Spartan surpasses other varieties tested in its much stiffer straw and as a nurse crop for seedings of alfalfa, sweetclover, red clover, and other forage crops.

**Row competition and its relation to cotton varieties of unlike plant growth.** N. I. HANCOCK (*Jour. Amer. Soc. Agron.*, 28 (1936), No. 11, pp. 948-957, fig. 1).—An attempt was made at the Tennessee Experiment Station to induce row competition by planting two cottons differing materially in morphological characters in different combinations of single-row plats (66 by 3 ft.) so that full and partly full expressions of their plant growth might be reflected upon each other. Each combination was in the trials 43 times during the years 1930-32, 1934. An effect from the unequal plant growth was evident. As expected, the small, less vigorous Delfos 6102 between its own border rows yielded more than when planted between the tall, vigorous California Acala. Likewise, the Acala, when placed between its own border rows had more competition and yielded less than when placed between Delfos. The extreme growth differences of these varieties also reacted the same way under the variable seasonal conditions. Plant competition in cotton would become an additive factor if the average were taken over a period of years. However, for a given season the degree of this effect was small and not significant in the Delfos combinations. Usually it was fairly large in the Acala combinations but of small significance. It is suggested that two-row plats be used for cotton varietal trials on soil of medium fertility.

**Registration of improved cotton varieties, I.** H. B. BROWN (*Jour. Amer. Soc. Agron.*, 28 (1936), No. 12, pp. 1019, 1020).—Cotton varieties registered as improved varieties and assigned registration numbers include Deltapine, formerly known as D. & P. L. 11, originally a plant selection from a hybrid between a noncommercial hybrid and D. & P. L. 10; Ambassador, formerly known as Stoneville-4, originally selected from Lone Star-65; and Washington, formerly known as Delfos-719, originally selected from Delfos 6102-324. Adaptations and characteristics are described briefly. See also an earlier note (E. S. R., 74, p. 629).

**A report on the production of cotton in the Panhandle of Oklahoma.** H. A. DANIEL ([*Oklahoma*] *Panhandle Sta., Panhandle Bul.* 61 (1936), pp. 13-16).—Yields secured in variety trials with cotton, 1924-36, at Goodwell are reviewed, supplementing an earlier report (E. S. R., 62, p. 829). Since the annual yield of seed cotton averaged only 202.1 lb. per acre during the period, cotton apparently cannot be grown economically in competition with wheat and sorghum in the southern high plains. Early frost and low temperature killed the plants before maturity in four different seasons during the period, indicating that the growing season at Goodwell is too cold and short for cotton production. Delfos 2 made the highest average yield, followed by Lightning Express and Oklahoma 44-11.

**Fertilizer placement for potatoes.** B. E. BROWN and G. A. CUMINGS (*Amer. Potato Jour.*, 13 (1936), No. 10, pp. 269-272).—Fertilizer placement experiments since 1931 (E. S. R., 73, p. 609), conducted cooperatively by the Maine, Michigan, New Jersey, New York, Ohio, and Virginia Truck Experiment Stations, the U. S. Department of Agriculture, and the Joint Committee on Fertilizer Application, consistently have indicated side placement to be best for potatoes in a number of important producing sections. Conclusions were that the placement of fertilizer in a narrow band at each side of the row about 2 in. away and on a level with or slightly below the seed piece should be a recommended practice. Potato planters with suitable fertilizer placement equipment are available, and many growers have adopted the side placement method of fertilizer application.

**A discussion of potato sprout emergence as related to fertilizer placement.** G. V. C. HOUGHLAND (*Amer. Potato Jour.*, 13 (1936), No. 12, pp. 343-

346).—Emergence data recorded and field observations made in cooperative experiments indicated that slow emergence of sprouts may be expected where fertilizer is placed underneath or mixed with the soil in direct contact with the seed. On the other hand, when fertilizer was placed in bands each side of the seed piece early growth stimulation resulted in a more rapid emergence of sprouts. "By avoiding a method of fertilizer distribution that tends to retard sprout emergence the grower will probably lessen the chances from *Rhizoctonia* injury, but by using side placement of fertilizer a combined advantage may be obtained resulting from the efficient use of the fertilizer applied coupled with early emergence."

**Influence of commercial fertilizers on yields, grades, and net value of potatoes in Hood River Valley, Oregon.** G. G. Brown (*Oregon Sta. Bul. 343* (1936), pp. 29, figs. 2).—The effects of commercial fertilizers varying in formula on yields and grades of potatoes and the effects of legume cover crops in the rotation on potato yields were studied, 1920–30, with the Netted Gem, Burbank, and Early Rose varieties grown on Parkdale loam in cooperative tests.

The heaviest yields of potatoes followed sweetclover, alfalfa, Hubam sweet-clover, vetch, or alsike green manures, while lowest yields came after red clover.

Fertilizers carrying a single nutrient element failed to produce economical yield increases over unfertilized plats, whereas nitrogen-phosphorus fertilizers with or without potassium were more effective. Yield increases over unfertilized plats, following the use of about equal amounts of plant food per acre, were not influenced significantly by variation in the nitrogen and phosphorus content. The greater tonnage of U. S. No. 1 potatoes from fertilized v. unfertilized plats was due to heavier yields rather than a major difference in respective grading percentages. The highest average percentage of No. 1 grade was associated with a relatively wide or intermediate nitrogen: phosphorus ratio.

Whole seed (3 oz.) of Netted Gem decidedly outyielded cut (halves of 3-oz. tubers) seed on both fertilized and unfertilized plats.

In the nitrogen and phosphorus series, when the amounts of plant food applied were 113, 239, 377, and 507 lb. of plant food per acre there were obtained 256, 291, 366, and 322 sacks of Netted Gem potatoes, an increase of 68, 110, 171, and 165 sacks over the unfertilized plats and an increase per 100 lb. of plant food applied of 60, 46, 45, and 32 sacks per acre. The 377-lb. rate, equivalent to 575 lb. of ammonium sulfate and 1,523 lb. superphosphate, was most economical, costing \$38.57, and the cost per sack of its yield increase did not exceed that from the 239-lb. rate. Net values per acre of increased yields for the 113-, 239-, and 377-lb. applications with potatoes at 75 ct. per sack were from \$39.66 to \$90.05. The costs per sack of the increase with Netted Gems following alfalfa green manure, when an application of 63 lb. per acre of nitrogen and phosphorus was increased progressively by multiples of from 2 to 8, varied as follows: 6.2 ct., 13, 11.2, 17.3, 17, 20, 22, and 25 ct.

Based on similar quantities of nitrogen-phosphorus plant food, fertilizers with additional potassium were less effective than nitrogen-phosphorus fertilizers only in small applications, were more effective in intermediate applications, and were similar to nitrogen or phosphorus alone in large applications. Equivalent quantities of nitrogen-phosphorus without potassium were much more effective than the total amount of plant food in a complete fertilizer on the basis of number of sacks increase per 100 lb. of nutrients used. The value of sulfur in nitrogen-phosphorus fertilizer combinations with or without potassium seemed to be established definitely. The value of potassium in sulfur-carrying fertilizers also was more positive than in nonsulfur fertilizers.

**The effect of naphthalene on germination of paddy seed, C. RAJASEKHARA MUDALIAR** (*Madras Agr. Jour.*, 23 (1935), No. 6, pp. 223-231).—Varying quantities of naphthalene did not affect the germinability of dry rice for 1 yr., but thereafter deterioration was evident. Varietal differences were apparent. Storage of rice varieties in gunny bags with naphthalene did not affect germination for 7 mo., but thereafter germination became prolonged. The growing embryo was not injured by naphthalene left with the seeds soaked in water before planting, but when seeds were subjected to naphthalene vapor after germination began the tender radicle and plumule were injured.

**A preliminary report of varietal differences in rapidity of germination in rice, C. L. PAN** (*Jour. Amer. Soc. Agron.*, 28 (1936), No. 12, pp. 985-989).—In germination tests made of 84 varieties of rice, the number of days required for germination differed with varieties. The rices pertaining to *Oryza sativa indica* germinated much faster on the average than those belonging to the *O. sativa japonica* group. Within the former group there was no significant association between time of maturity and rapidity of germination.

**Comparative hardness of tasseled versus untasseled canes, C. E. PEMBERTON** (*Hawaii. Planters' Rec. [Hawaii. Sugar Planters' Sta.]*, 40 (1936), No. 4, pp. 315-317, fig. 1).—By means of a special instrument, untasseled canes of nine sugarcane varieties were found to be harder than those which had arrowed. The stalks in any variety which sucker profusely after tasseling were not as soft as those of the same variety which suckered very weakly. The process of dying or disintegration after flowering becomes very greatly suspended in all parts of the stalks if side shoots are vigorous. The greater softness of the tasseled canes may explain the greater incidence of beetle borer infestation in some areas in Hawaii where certain varieties tassel very heavily.

**Effect of age upon the absorption of mineral nutrients by sugar cane under field conditions, A. AYRES** (*Jour. Amer. Soc. Agron.*, 28 (1936), No. 11, pp. 871-886, figs. 10).—The effect of age upon the percentage composition of the sugarcane plant and of the changing demands which the growing cane makes upon the soil for mineral nutrients was studied at the Hawaiian Sugar Planters' Experiment Station, 1933-34. The percentage compositions (mineral) of the leaves and of the stalk of the plant were influenced markedly by the plant's age, particularly during the early months of growth. Dry matter of dead cane leaves contains much lower concentrations of potassium and nitrogen than that of green leaves, this being attributed to the migration of these nutrients from the leaves back to the stalk before the leaves become physiologically inactive.

The plant was found to take up potassium and silicon to the greatest extent, while nitrogen and phosphorus were absorbed in relatively moderate quantities. Of the nutrients studied, calcium and magnesium were absorbed in least amount. The absorption rate of the several mineral nutrients varied with the plant's age, but not always in the same degree. For all elements studied, except silicon, it reached maximum values by the age of 3 mo., during which period about 10 percent of the first year's uptake of phosphorus and potassium and nearly 25 percent of nitrogen occurred. After the age of 6 mo. with nitrogen and after about 10 mo. with calcium, magnesium, and potassium, the absorption rates diminished, whereas uptake of silicon and phosphorus continued at essentially constant rates until the experiment ended at 14 mo. Potassium and nitrogen were absorbed less rapidly just after the acquirement of maximum quantities of these nutrients by the leaves. It appeared that absorption of nitrogen, potassium, and probably other nutrients by sugarcane is primarily a function of the age or stage of development of the plant and not of the growth rate.

Pronounced differences were found in the distribution of the elements between the components of the crop, being most marked in phosphorus and silicon.

The quantities of these nutrients in the stalk (at the final harvest) amounted to 60 and 15 percent, respectively, of the totals taken up. Examination of the distribution of potassium in the stalk suggested that as the meristematic tissues mature they lose potassium by upward migration.

The influence of superphosphate and light lime applications alone and in combination on the composition of sweet clover, H. E. MYERS and W. H. MERZGEB (*Jour. Amer. Soc. Agron.*, 28 (1936), No. 12, pp. 976-984).—Under conditions prevailing in eastern Kansas, ordinary applications of superphosphate alone or with a light application of lime did not increase consistently the percentage of phosphorus in sweetclover for the Kansas Experiment Station. Neither did light lime applications increase the calcium percentage in the plants. The variation in composition of the sweetclover from untreated plats in the different counties exceeded the variation in composition resulting from treatments in any one county. Large response from application of phosphorus or calcium tended to be associated with a smaller percentage of the corresponding element in the plant, and little or no response appeared to be associated with increased percentages of these elements. Light lime applications showed a marked tendency to reduce the percentage of phosphorus and nitrogen in sweetclover. Superphosphate tended to produce a lower calcium percentage in the plant, but was less consistent on the nitrogen. Superphosphate plus lime was quite inconsistent in its influence on the percentage composition of all the elements considered. Effects of treatment tended to be greater and more consistent in the first year crop than in the second.

Timothy selection for improvement in quality of hay, M. W. EVANS and J. E. ELY (*Jour. Amer. Soc. Agron.*, 28 (1936), No. 11, pp. 941-947).—The growing habits of the leaves on plants of three strains of timothy and of the relation of their condition to hay quality was studied in 1935 by the U. S. Department of Agriculture, cooperating with the Ohio Experiment Station. In the plats of both the early and the late selection, the leaves remain green longer than in plats of ordinary timothy. The number of days for the upper five leaves to emerge, remain green, and become dry averaged for the early strain 53, medium, common ordinary timothy 51.5, and the late strain 58.8 days. As the season advanced, the color reading of the hay from samples of all strains showed a constant decrease in hue, indicating the degree of greenness in the grades of hay and in its protein content. These values, correlated with the number of green leaves on the stems, were generally higher for the late selection than for the early selection or ordinary timothy. See also an earlier note (E. S. R., 75, p. 623).

Registration of improved wheat varieties, X, J. A. CLARK (*Jour. Amer. Soc. Agron.*, 28 (1936), No. 12, pp. 1017, 1018).—Varieties of wheat approved for registration (E. S. R., 74, p. 632) in 1936 included Ramona, derived from Hard Federation  $\times$  Bunyip, and Erect, derived from Dicklow  $\times$  Hard Federation. Records of performances and brief descriptions are given.

Wheat varieties in Washington in 1934, E. F. GAINES and E. G. SCHAFER (*Washington Sta. Bul.* 338 (1936), pp. 24, figs. 3).—The 1934 survey of wheat varieties (E. S. R., 66, p. 32), made in cooperation with the U. S. Department of Agriculture, indicated a normal ratio of about 60 percent winter wheat to 40 percent spring wheat, and that fewer varieties than formerly were being grown. Production percentages by classes included hard red spring Marquis 1 percent; hard red winter Turkey 21, Rldit 8.2, and Kanred 0.2; soft red winter Triplet 5.7, Red Russian 0.6, Jones Five 0.4, and Hybrid 123 0.1; hard white Baart 19.9, Bluestem 1.8, and Hard Federation 0.1; soft white Federation 13.5, Fortyfold 3.1, and Thompson 0.7; and white club Albit 20.7, Hybrid 128 1.3, and Jenkin 0.2 percent. Red wheats comprised 37.2 percent and white wheats 61.3 percent of the total; hard wheats 52.3 percent and soft wheats 46.3 percent. The adapta-

tion of the six leading varieties are noted briefly and their distribution areas indicated on outline maps. Farmers evidently were concentrating increasingly on the tested and recommended superior varieties. Indications were that if the current trend continues the 30 varieties listed as grown in 1934 in a few years would be reduced to Turkey, Riddit, Baart, Albit, Hymar, and Federation.

**Handbook of Canadian spring wheat varieties**, L. H. NEWMAN, J. G. C. FRASER, and A. G. O. WHITESIDE (*Canada Dept. Agr. Pub. 538 (1936), pp. 51, figs. 45*).—The origin, description and illustration, milling and baking qualities, status and distribution, together with a determinative key, are given for 37 varieties of spring wheat grown in Canada.

**Studies on the refractive indices of expressed juice in wheat seedlings**, K. EBIKO (*Jour. Amer. Soc. Agron., 28 (1936), No. 11, pp. 887-899*).—The refractive indices of expressed juice as a physicochemical character of wheat seedlings were determined on eight winter and six spring wheats at the Sakhalin (Karafuto, Japan) Central Experiment Station.

The refractive indices of the winter varieties exceeded those of the spring wheats on an average when the plants were exposed to low temperature conditions before measurement. In comparisons between three temperature cultures—20°-32°, 5°-10°—and 0°-5° C., respectively—the greater refractive index occurred with the lower temperature, indicating the great effect of environmental factors. The hardy varieties had greater refractive indices, in general, than the nonhardy sorts under hardened conditions. Greater refractive indices were always observed in the juice from unfrozen plants as compared with frozen plants. Within the limits of the experiment, an accurate correlation was not observed between the content of total solids in expressed juice estimated by the refractometer and the monosaccharide content in seedling tissues obtained by chemical analysis.

**[Seed investigations]** (*New York State Sta. Rpt. 1936, pp. 85, 86, 87*).—The quality of agricultural seeds sold in New York, as revealed by official tests, is described, with brief observations from studies of viability of fescue seed and seed wheat, a drill survey of winter wheat (E. S. R., 76, p. 330), and further studies of the physiology of seed germination.

**[Report of Canadian Seed Growers' Association, 1935-36]** (*Canad. Seed Growers' Assoc. Ann. Rpt. 1935-36, pp. [1]+110, figs. 13*).—A report of the activities of the association during 1935-36 and of its annual meeting July 9-11, 1936. Papers of interest to agronomists include The Origin and Development of the Canadian Seed Growers' Association, by L. H. Newman (pp. 46-59); The Work of the Canadian Seed Growers' Association: Its Objective and Plan of Operation, by R. Summerby (pp. 60-64); The Use of Registered Seed in the Scheme of Canadian Agriculture, by H. G. L. Strange (pp. 65-70); The Present Policy of Registration of the Several Groups of Crops (pp. 71-74) and The Value of Standard Seed Stocks in Root Seed Production (pp. 95-99), both by W. T. G. Wiener; The Use of Registered Seed, by W. J. W. Lennox (pp. 75-77); The Rudiments of Pollination and Fertilization of Farm Crops, by W. H. Wright (pp. 78-82); An Analysis of Some Varieties of Oats Grown in Nova Scotia, by K. Cox (pp. 83-89); and Root Seed Production, by L. C. Raymond (pp. 90-94).

**The spurge nettle**, R. T. STEWART, R. G. REEVES, and L. G. JONES (*Jour. Amer. Soc. Agron., 28 (1936), No. 11, pp. 907-913, figs. 4*).—Spurge nettle (*Jatropha texana*), under study at the Texas Experiment Station and characterized by an enormous root and relatively small aerial parts, normally grows on very poor sandy soils and seems to be affected little by drought and remains green when other plants wither and die. Preliminary experiments on its control by chemicals and smothering are reported.

## HORTICULTURE

[**Horticultural investigations by the Bureau of Plant Industry**] (*U. S. Dept. Agr., Bur. Plant Indus. Rpt., 1936, pp. 5, 6, 10, 11, 12, 13, 14*).—Among studies, the progress of which are discussed, are those dealing with the growing and harvesting of pyrethrum and *Cracca virginiana*; the composition of hops as related to maturity and environment; the breeding of hops resistant to mildew; the breeding of peaches and grapes; development of nematode-resistant grape stocks; the irrigation of lemons; propagation, pruning, and tree thinning of pecans; the breeding of almonds, lettuce, beans, tomatoes, and muskmelons; rootstocks for roses; and the testing of rubber-producing plants such as *Asclepias*.

[**Horticultural studies by the Arkansas Station**] (*Arkansas Sta. Bul. 337 (1936), pp. 50-53, 54-58*).—Included are brief notes on the comparative rate of pollen tube growth in selfed and crossed apple flowers, effects of pistil and ovary extracts on the growth of pollen tubes, and factors causing sterility in the Stayman Winesap apple, all by J. R. Cooper; growth and fruiting of the tomato, by V. M. Watts; fertilizers for the peach, by Cooper; and for vegetables, by Cooper and Watts; effect of soil conditions such as texture and reaction and of plant vigor on the composition and character of strawberry fruits, and effect of fertilizer ingredients on the growth of the strawberry, both by Cooper; effect of soil acidity on production of vegetables, by Watts and Cooper; pruning of apples, by Cooper; breeding of tomatoes for disease resistance, and variety testing of peas, both by Watts; factors influencing the uneven ripening of grapes, effect of rootstock on growth and fruiting of American grapes, and testing of new fruits, all by J. E. Valle.

[**Horticultural studies by the Delaware Station**] (*Delaware Sta. Bul. 203 (1936), pp. 35-37*).—Information is given relative to the following studies: The relation of curculio injury to the premature dropping of apples and peaches, by L. R. Detjen and L. H. Strubinger; and normal variation in growth of apple trees upon own and seedling roots, by F. S. Lagasse.

[**Horticultural investigations by the Michigan Station**] (*Michigan Sta. [Bien.] Rpt. 1935-36, pp. 22, 39, 40, 42, 43*).—Among studies, the progress of which is briefly noted, are those dealing with protective coatings for nursery stock, fruits, and vegetables; calcium cyanamide as an orchard fertilizer; sod culture for sour cherries; characteristics of good orchard soils and sites; and the breeding of new greenhouse tomatoes.

[**Horticultural investigations by the Missouri Station**] (*Missouri Sta. Bul. 370 (1936), pp. 63-67, 68, 69*).—Information is presented on studies relating to the effect of length of day upon reproduction in horticultural plants, and upon apple pollination, both by A. E. Murneek; a comparison of cyanamide, sulfate of ammonia, and nitrate of soda as fertilizers for apple trees, by Murneek and G. E. Smith; unbalanced fertilization of fruit trees, by Murneek and E. J. Gildehaus; the use of fertilizers on strawberries, by Murneek and J. H. Long; the nutritional requirements of the grape, by H. G. Swartwout; varieties of watermelons, by R. A. Schroeder; stimulation of lateral buds on plants, by C. G. Vinson and F. Horsfall, Jr.; yellows-resistant cabbage varieties, by Swartwout and Schroeder; and wilt-resistant tomato varieties, and fruit setting in midwinter tomatoes, both by Schroeder.

[**Vegetable crop investigations by the New York State Station**] (*New York State Sta. Rpt. 1936, pp. 38, 88-92*).—Included in this progress report is information on the following studies: Effect of time of fruit set and harvest on pumpkins and squashes; placement of fertilizer for peas, beans, tomatoes,

and cabbage; residual effect of fertilizer on subsequent crop of peas; comparison of different kinds of fertilizer; fertilization of spinach; breeding of squash, muskmelons, and tomatoes; and varietal description and classification of vegetables.

**Vegetable fertilizers in Arizona, M. F. WHARTON** (*Amer. Soc. Hort. Sci. Proc.*, **32** (1935), pp. 552-554).—Experiments conducted by the Arizona Experiment Station on an irrigated soil at Mesa which is characterized by high nitrates, high potassium, and low phosphates showed definitely the need of applying nitrogen and phosphorus. The need for N was explained by the fact that under irrigation nitrates moved up and out of the root zone by capillary movement and evaporation. Deep-rooted crops, such as carrots, turnips, and beets, obtain a sufficient supply of N from the soil. In the case of head lettuce, there was found a well defined correlation between mature head weight and the phosphate content of the soil. Where available phosphate was greater than 10 p. p. m. there was little response to applications. The use of slowly available sources of N promoted desirable color and texture in lettuce.

**Nitrate requirements of truck crops on newly cleared land, L. M. WARE** (*Amer. Soc. Hort. Sci. Proc.*, **32** (1935), pp. 555-559).—Observing that despite liberal applications of phosphorus crop yields were extremely low on freshly cleared land at the Gulf Coast Substation, Fairhope, unless excessively large amounts of quickly available nitrogen were applied, greenhouse and laboratory studies were conducted by the Alabama Experiment Station to determine the causes. Much larger yields were obtained in the second year from non- and low-nitrogen treatments, and this improvement was even evident with late-maturing and late-season crops in the first year. Nitrate determinations of the soil of the nonnitrogen unplanted plots showed in the first season a complete disappearance after the first 2 weeks with a reappearance in very small amounts about 4 weeks later. Under the same conditions in the second year nitrates increased steadily for 3 mo., reaching an amount five times the original. The author suggests the probability that there is a "tying up" of soil nitrates in fresh soil by bacteria the growth of which is encouraged by the large amount of organic matter present. Applications of nitrate in amounts sufficient to supply both the bacteria and the crop permit the successful cropping of freshly cleared soils.

**Experiences with rapid chemical tests for the determination of nutrient deficiencies in vegetable crops, R. L. CAROLUS** (*Amer. Soc. Hort. Sci. Proc.*, **32** (1935), pp. 579-583).—Stating that fairly successful results have been secured by the Virginia Truck Experiment Station by testing the extracted sap of the stem and petiole of 19 crop plants for nitrate nitrogen, phosphate phosphorus, magnesia, potassium, and, to a lesser extent, for calcium oxide and ammonia, the author presents the results of tests for nitrate nitrogen, phosphate phosphorus, potassium oxide, and magnesium oxide conducted with collards, black cowpeas, and tomatoes grown in the greenhouse on four soils known to be deficient in N, P, K, and Mg, respectively. The plants in the N-deficient soil were extremely high in phosphate P and high in K. Limiting the P supply resulted in a marked increment in nitrate N and a great decline in phosphate P. K deficiency resulted in a low K content and a slightly higher nitrate content. Mg deficiency resulted in low magnesia, rather low nitrate, and low phosphate P, and usually an increased K content.

Analyses of cabbage grown in the open showed a correlation between the magnesia content of the soil and that of the plants. Rapid chemical tests showed a correlation between low K content in rhubarb petioles and the browning of the leaf edges. Manganese deficiency of the soil was exhibited in lowered con-

tent in the plant. In the case of sweetpotatoes, applications of N fertilizer had little effect on the total N in the tissues of the stems but did increase the nitrate N in the sap. The value and limitations of the rapid chemical method are discussed.

**Effect of previous cold storage on the respiration of vegetables at higher temperatures,** C. O. APFLEMAN and C. L. SMITH (*Jour. Agr. Res. [U. S.]*, 53 (1936), No. 8, pp. 557-580, figs. 15).—Information is presented on the results of studies by the Maryland Experiment Station on the respiratory response of various vegetables and the dahlia placed at 22° C. following storage for various periods at 2.5°. The respiratory intensity varied greatly in the different species immediately after harvest. In the case of carrots, beets, and turnips, the respiration rate declined steadily until the end of the respiration period, while in the potato, sweetpotato, parsnip, onion, and dahlia respiration declined rapidly at first, then more slowly until it began to fluctuate around a fairly constant average rate for the remainder of the period. The effect of cold storage on the initial respiration rate at higher temperatures varied with the different species, being very pronounced in potatoes but not detectable in carrots. Vegetables with a relatively high percentage of starch and in which there was a rapid shifting of the carbohydrate equilibrium with temperature changes were the ones that showed the greatest increase in the initial respiratory rate when transferred from low to high temperature. There was no direct correlation between the content of either total or reducing sugars and the respiration rate in the vegetables studied. The authors state the sugar that accumulates in the starchy vegetables at low temperatures is not responsible for the initial respiration on transfer to warmer environments.

**Loss of weight from celery during marketing as influenced by wrapping, trimming, temperature, and humidity,** P. WORK (*Amer. Soc. Hort. Sci. Proc.*, 32 (1935), pp. 569-578, figs. 4).—Experiments conducted by Cornell University upon the relationship of various factors, such as temperature, relative humidity, wrappers, and trimming of stalks, on the retention of weight and attractive appearance during the marketing period showed very clearly that low temperature and high relative humidity are essential to the good keeping of celery. Wrapping and trimming were especially important under open display conditions such as prevail in the ordinary market. Waxed paper retarded losses more than did parchment paper when the bunches were isolated and in the open. It was observed that the decline in salability fairly closely accompanied weight losses.

**Nitrogen nutrition and chemical composition in relation to growth and fruiting of the cucumber plant,** R. B. DEARBORN ([*New York*] *Cornell Sta. Mem.* 192 (1936), pp. 26, pl. 1, figs. 2).—Using a strain of White Spine cucumber which had been selfed and selected for nine generations at the University of Illinois, plants grown under high and low planes of nitrogen nutrition and treated differently with respect to defoliation and fruit removal were observed as to growth and fruiting and the content of various nitrogen and carbohydrate materials.

Plants receiving a low supply of N grew more slowly and produced fewer and smaller fruits than did plants with abundant N. It was observed that in both the high and low N groups plants allowed to produce fruit had a higher rate of vegetative extension for a period of 10 to 14 days after pollination than did defoliated plants in the same groups. After the initial period of stimulation, the presence of growing fruits had a depressing effect on growth, particularly the vegetative portions. However, when the entire plant was considered, fruiting plants produced more green or dry weight than did defoliated plants,

indicating a higher rate of metabolic activity and a more rapid synthesis and storage of food.

From the compositional standpoint, high N plants in general had a higher percentage content of all forms of N than did comparable low N plants. Fruit-bearing plants contained higher percentages of lipid, residual, and total N and lower percentages of nitrate, amino, and amide N than did defoliated plants. Apparently in defoliated plants there was a less rapid absorption of nitrates and a more rapid rate of conversion in the formation of amino and amide N. The utilization of amino and amide N was apparently impeded in the absence of fruits.

Low N plants, in general, had higher percentages of carbohydrates than did high N plants, apparently because of the lower rate of utilization. Fruit bearing plants were found to have a lower percentage of carbohydrates than defoliated plants.

Summing up the studies, the author states that the results support the findings of Nightingale (E. S. R., 57, p. 216), but that there was no evidence that changes in composition are the cause of changes in growth habits. It is considered possible, on the other hand, that changes in the type of growth may initiate changes in chemical composition. Incidentally, plants with a high N supply produced more pistillate and fewer staminate flowers than did the low N plants. A relatively high level of N nutrition was necessary for the production of well shaped and well colored fruits.

**Movement of salt (alkali) in lettuce beds under irrigation,** M. F. WHARTON and W. T. McGEORGE (*Amer. Soc. Hort. Sci. Proc.*, 32 (1935), pp. 548-551, figs. 4).—Analyses of samples of soil collected by the Arizona Experiment Station from an area on the experimental farm at Mesa, typical of that used for lettuce production, showed that during the culture of lettuce on raised beds under irrigation there is a considerable movement and accumulation of soluble salts, such as nitrates, chlorides, and sulfates of alkali and alkaline earth bases in the beds. The rate and amount of salt movement was correlated with bed type and quality and quantity of irrigation water. The greatest salt accumulation occurred in the center of convex beds. The subsoil beneath the beds had a higher salt content than the surface soil of the furrows. Potassium moved as other salts but more slowly. Phosphate movement was negligible.

**Retarding effect of hardening on yield and earliness of tomatoes,** A. M. PORTER (*Amer. Soc. Hort. Sci. Proc.*, 32 (1935), pp. 542-544).—Hardening of tomato plants for 10 days in a cold frame was found by the Connecticut State College to reduce the early yield of marketable fruits. Hardening increased the total yield for the entire growing season but not sufficiently to increase profitable returns over the nonhardened plants.

**Storage losses in canning tomatoes,** F. C. GAYLORD and J. H. MACGILLIVRAY (*Amer. Soc. Hort. Sci. Proc.*, 32 (1935), pp. 545-547).—Working in cooperation with commercial canning factories, the Indiana Experiment Station found that the loss in weight of tomatoes in the interim between harvesting and processing is proportional to the duration of the period held. Loss was greater in the sun than in the shade. The higher the grade the lower the weight loss. Storage resulted in an increase in culls, a decrease in No. 2, and usually a decrease in No. 1 fruits. With long periods of storage the detrimental effects were more marked in the sun than in the shade. With respect to yield and color of pulp, about 40 hr. of delay between picking and processing resulted in a significant loss in weight and decrease in quality and yield of pulp without any improvement in color.

**Further studies on the occurrence of cracks in tomato fruits,** W. A. FRAZIER (*Amer. Soc. Hort. Sci. Proc.*, 32 (1935), pp. 536-541, fig. 1).—Continu-

ing investigations on the cracking of tomato fruits (E. S. R., 73, p. 475), it was noted that cracking was more severe on plants pruned to a single stem than on nonpruned plants. Removal of two-thirds of the leaves from the pruned plants resulted in a decided reduction in cracking as compared with pruned untreated plants. None of the three principal fertilizer elements, N, P, or K, even when applied liberally had any appreciable effect on cracking. The author suggests that the two types of cracking, namely, radial and concentric, may have different causes. Since leaf removal caused no appreciable difference in water content or carbohydrate composition, the author suggests the possibility that smaller size of fruit on the defoliated plants may have been a factor.

**Fruit varieties for Missouri**, T. J. TALBERT (*Missouri Sta. Bul.* 371 (1936), pp. 56).—In connection with lists of desirable tree and bush fruits for commercial and home planting, the author presents information on the origin of new varieties by seed and by mutation, pollination requirements, soil preferences, and general trends in the improvement of existing varieties.

[**Pomological investigations by the New York State Station**] (*New York State Sta. Rpt.* 1936, pp. 63-84).—Progress statements are presented upon studies dealing with varieties of fruits; breeding of fruits, particularly the pear, cherry, peach, apple, grape, and raspberry; orchard management; winter injury to fruit trees; nutritional requirements of orchard and small fruits; orchard cover crops; relation of the nutritional status of the tree to disease and spray reactions; propagation of the quince; the adaptability of the Malling rootstocks; top working young apple trees; rootstocks for cherries and plums; stock and scion relationships to winter injury; handling of dormant nursery stock; germination of fruit seeds; value of *Pyrus betulaefolia* as a stock for pears; artificial culture of fruit tree embryos; vascular anatomy of the apple; fruit development as influenced by killing the embryo; fertilization, pruning, and breeding of grapes; taxonomy and breeding of cucurbits; metaxenia in the apple; chromosomal structure in the apple and grape; viability of fruit pollen; and variety and cultural trials with hops.

**Root systems of some apple clones**, F. B. LINCOLN (*Amer. Soc. Hort. Sci. Proc.*, 32 (1935), pp. 323-328, figs. 5).—Photographic reproductions are presented of the root systems of the following 3-year-old self-rooted apple trees produced at the University of Maryland by trench layering: King, Talman, Baldwin, Northern Spy, Jonathan, Henry Clay, Red Rome, Potter, Delicious, Gano, Duchess, Red Gravenstein, Hume, Early McIntosh, McIntosh, Keetosh, Crimson Beauty, Ferry, Stayman, and York Imperial.

**Growth study of the apricot fruit** [I], II, O. LILLELAND (*Amer. Soc. Hort. Sci. Proc.*, 27 (1930), pp. 237-245, figs. 2; 32 (1935), pp. 269-279, figs. 7).—Measurements at the California Experiment Station, Davis, of the developing fruits of the Royal apricot, led to the following deductions in part 1:

Whether measured on a fresh- or dry-weight basis, the flesh, endocarp, and kernel do not develop simultaneously. On a green-weight basis, the kernel and endocarp make their major increase relatively early, while the flesh makes its increase considerably later. With reference to total solids, the endocarp makes very little gain during the first month, increases rapidly during the second month, and shows no gain in the last month. On the other hand, the kernels make little gain in total solids during the first two months but thereafter continue to gain until harvest. The flesh makes its greatest increment in dry matter during the final month of development of the fruit.

Continuing the study, the author found again three well-defined periods of growth in the apricot fruit. To determine the effect of temperature on pericocity, a limb of a Blenheim apricot tree was enclosed in a celloglass structure in which supplemental heat was supplied at night with electric plates. The

acceleration of growth during the early season in the heated shelter was striking, abbreviating the first growth period by about 22 days. No reduction occurred in the length of the second period in the shelter. The results suggest that the theory set forth by other investigators that growth processes elsewhere in the tree may control periodic development of the fruit is untenable. Fruit in the heated chamber exhibited periodicity but distinctly nonsynchronous with unprotected fruit of the same tree. It is considered likely that temperature influences are the determinants which produce synchronism in growth. Shoot growth in the shelter was also advanced by the higher night temperatures. The period of maximum shoot extension was not coincident with the period of minimum fruit enlargement, suggesting no dominance of vegetative growth over fruit enlargement. While the development of the various constituents was advanced in the fruits under shelter, the same orderly sequence was maintained as in the outside fruits. Heat units and base temperatures are calculated for the various periods of growth in the Blenheim apricot.

**Observations on fruit setting in the cherry in 1936, J. C. KREMER** (*Michigan Sta. Quart. Bul.*, 19 (1936), No. 2, pp. 94-96).—Poor setting of the Montmorency and other sour cherries in the summer of 1936 was found to be associated with unfavorable weather conditions during the pollination period. In southern Michigan, abnormally high temperatures rushed the flowers through their development and nectar flow was limited by the low humidity. In northern Michigan, flowers opened after the hot period but the temperature was so low as to depress nectar secretion and bee flight. Observations show that where abundant strong colonies of bees were present there were better than average sets of cherries. Nectar secretion took place largely in the temperature range from 65° to 75° F. The sweet cherry, blooming earlier than the sour, encountered more favorable pollination weather.

**Influence of irrigation upon important small fruits, W. S. BROWN** (*Oregon Sta. Bul.* 347 (1936), pp. 37, figs. 3).—Presenting the results of a 10-yr. study on the irrigation of small fruits, the Ettersburg 121 strawberry failed to respond to irrigation and showed a loss in both yield and net income. Irrigation resulted in average gains in the yield of the Evergreen blackberry, loganberries, strawberries, red raspberries, and black raspberries of 36.3, 58.4, 91.5, 58.4, and 110.5 percent, respectively. Results with black and red raspberries were also discussed in an earlier bulletin (E. S. R., 65, p. 740).

In the case of the Evergreen blackberry, both the acid and sugar content of the nonirrigated berries were slightly higher than in irrigated fruits but the differences were not sufficient to be noticeable to the taste. Analyses of loganberries showed no significant differences in acid or sugar content that could be attributed to irrigation. Strawberry irrigation resulted in no noticeable changes in acid content, but in the Marshall and Corvallis varieties sugar was slightly greater in the nonirrigated berries and the reverse was true in the Narcissa strawberry.

Drip tests of Evergreen blackberries showed no material difference in the holding-up qualities due to irrigation. In loganberries, there was a slightly higher percentage of solids in the irrigated fruits but the difference was not enough to affect the appearance of the canned product. In strawberries, drip tests showed no material difference in the solids that could be related to irrigation. In the three fruits, Evergreen blackberry, loganberry, and strawberry, irrigation resulted in a more attractive fresh fruit, that is, brighter in color and firmer in appearance.

The economic results of irrigation were directly related to price per pound in the Evergreen blackberry. The highest net profit was obtained in 1930 when heavy yields were coupled with good prices. In 1932, with very low prices

and heavy yields, the net losses were large. In the loganberry, type of pruning proved an important factor in economic results. Under irrigation full length canes yielded a substantially larger gross income than did short pruned canes. All strawberries except Ettersburg 121 showed a profit from irrigation for each year. Black raspberries, on the average, failed to be profitable with or without irrigation. Red raspberries returned a substantial profit from irrigation in years of good prices.

**Inheritance in blackberries**, T. E. ODLAND and A. E. STENE (*Amer. Soc. Hort. Sci. Proc.*, 32 (1935), pp. 423-426).—In this preliminary report on an investigation at the Rhode Island Experiment Station designed primarily to study the inheritance of thorniness and habits of growth, the authors state that the Mayes Thornless and Santa Rosa were the only thornless varieties found and that these two are to be used largely in the breeding work. The best method of germinating blackberry seed was to store for 3 mo. at 33°-35° F. and sow in late September. Tabulated data are presented on the results of cross- and self-pollinations through 1935. The results suggest that thornlessness is heritable, and in one cross it appeared dominant. Trailing habit of growth was apparently dominant over upright.

**The inheritance of suckering and tip layering in purple raspberry seedlings**, A. S. COLBY (*Amer. Soc. Hort. Sci. Proc.*, 32 (1935), pp. 427-429).—Observations at the Illinois Experiment Station on five groups of purple raspberries, derived by crossing Quillen with Golden Queen, Latham, June, Starlight, and Ranere, showed one group, namely, Quillen × Ranere, to fail to propagate by both suckers and tip layers. Quillen is believed homozygous for tip layering because no suckering was found in 579 seedlings obtained by self-pollination. Since about 25 percent of the plants of the Golden Queen, Latham, and Starlight crosses suckered, the possibility is suggested of a simple monohybrid character. Quillen × June yielded only 7 percent suckering plants. The absence of suckers in the Quillen × Ranere group suggests that absence is apparently dominant over presence of suckers. Suckering has the advantage that a greater number of plants can be propagated in a brief period.

**The moisture content of strawberries as influenced by growing conditions**, G. M. DARROW and G. F. WALDO (*Amer. Soc. Hort. Sci. Proc.*, 32 (1935), pp. 393-396).—Records taken by the U. S. Department of Agriculture over a 3-yr. period on the dry weight of the fruits of many different varieties of strawberries grown without irrigation showed a range between a minimum of 4.9 percent in the first picking of the seedling U. S. D. A. No. 652 in 1929 to a maximum of 13 percent in 1929. The maximum was also recorded in the last harvest of Blakemore in 1930. Dry weight percentage in general increased with the advancing season in all 3 yr. The several varieties maintained their relative positions rather consistently during the 3 yr. In any variety large berries had a lower percentage of dry weight than did small berries. Heavy applications of nitrogen under conditions of ample but not excessive soil moisture appeared to result in lower dry weight.

**Some effects of nitrogen fertilizer and irrigation on the growth and blossoming of the Howard 17 strawberry**, E. W. GREVE (*Amer. Soc. Hort. Sci. Proc.*, 32 (1935), pp. 397-400).—A total of 450 lb. of nitrate of soda was applied in equal applications on June 5, July 12, and August 20 to Howard 17 strawberries set in the field on April 21. In addition, supplemental irrigation was provided to part of the fertilized area and to part of the nonnitrated controls. The runner plants were placed in a double row with two series on each side of the parent. Nitrogen had a depressing effect on the number of runners formed and also apparently on the number of leaves per plant. The plants receiving no nitrogen and no irrigation produced longer runners than

the nitrated plants. The fewer number of leaves on the nitrogen plats was reflected in the results of chemical analyses of plants collected in September and October, the data showing higher carbohydrate-nitrogen ratios in the no-nitrogen groups. The generally slight effects of irrigation in the experiment are believed due to the heavy rainfall during the latter part of the growing season.

**Effects of late summer and fall applications of nitrogen on fruit production in the strawberry,** R. A. VAN METER (*Amer. Soc. Hort. Sci. Proc.*, 32 (1935), pp. 401-404).—Studies at the Massachusetts Experiment Station of the effects of nitrogen on the fertility of the Howard 17 strawberry showed in general little indication that summer and autumn nitrogen applications were either significantly beneficial or harmful under the conditions, which included ample phosphorus and potassium and a soil of natural medium fertility.

**Bunch grapes in north Georgia,** J. E. BAILEY (*Georgia Sta. Circ.* 112 (1937), pp. 4).—In connection with general varietal, cultural, and pruning information, tabulated analyses are presented on total solids and titratable acidity in the juices of several varieties of northern or bunch grapes.

**A giant macadamia nut,** C. E. PEMBERTON (*Hawaii. Planters' Rec. [Hawaii. Sugar Planters' Sta.]*, 40 (1936), No. 4, pp. 303-306, figs. 2).—A brief account is presented of the discovery in northern Queensland, Australia, of a single tree of *Macadamia whclani* Bail., bearing very large edible nuts. The first importation of these nuts to Hawaii failed to germinate, due apparently to immaturity at the time of collection.

**Culture of tung-oil trees in Louisiana,** J. C. MILLER and W. D. KIMBROUGH (*Louisiana Sta. Circ.* 17 (1936), pp. 4).—This contains general information on culture, propagation, harvesting, protection from pests, and utilization.

**Some recommended bulbs, shrubs and trees for the Panhandle of Oklahoma,** H. J. THOMSON ([*Oklahoma*] *Panhandle Sta., Panhandle Bul.* 61 (1936), pp. 3-12).—Varieties and species of ornamentals that have proved desirable for planting in western Oklahoma are discussed, with brief cultural suggestions, notes on comparative hardness, etc.

**Farmstead shelterbelts** (*U. S. Dept. Agr., Bur. Plant Indus. Rpt.*, 1936, p. 7).—The results are very briefly summarized of tests of various tree species under the trying conditions of the northern Great Plains.

**Adding to the attractiveness and comfort of the ranch home** (*Montana Sta. Rpt.* 1935, pp. 48-52, fig. 1).—General information is presented on the establishment of shelterbelts, winter protection of red raspberries, culture and maintenance of the vegetable garden, and temperature requirements for celery, cabbage, onions, and other crop plants.

## FORESTRY

**Research [by the Forest Service, 1936],** F. A. SILCOX (*U. S. Dept. Agr., Forest Serv. Rpt.*, 1936, pp. 45-57).—Results are briefly noted from comparative studies of naturally sown and transplanted seedlings; screen protection of seeds against rodents; reproduction following clear cutting, and disturbance of the forest floor; selection types of cutting; stimulation of root production; reclamation of aspen areas; production of hybrid pines; budding, grafting, and breeding pines; fire resistance of individual species; conservation methods in naval stores production; cost-of-production range studies; range management; influence of growth conditions on wood quality; minimum sizes of trees economical to cut; chemical seasoning of wood; producing a wood plastic; pulp and paper problems; economic studies of timber management; influence of

forest cover on stream flow; and evaporation and transpiration on semidesert watersheds.

[Forestry studies by the Arkansas Station] (*Arkansas Sta. Bul.* 337 (1936), pp. 58, 59).—There are discussed briefly the results of the following studies, all conducted by L. M. Turner: Germination and seedling growth of various forest tree species, root development of *Pinus echinata* and *P. taeda*, water and nutrient requirements of *P. echinata* and *P. taeda*, and site indices determinations for forest species on various soil types.

[Forestry studies by the Michigan Station] (*Michigan Sta. [Bien.] Rpt.* 1935-36, pp. 37, 38).—Brief reports are presented on the soil requirements and effects of release cuttings upon the growth of black spruce, on the germination of white pine seed, and on the economics of taxing forest land.

The forest influence on streamflow under divergent conditions, C. G. BATES (*Jour. Forestry*, 34 (1936), No. 11, pp. 961-969).—Comparing results of observations in hilly areas of southwestern Wisconsin and adjacent Minnesota with standards set up by the Wagon Wheel Gap streamflow experiments in Colorado (E. S. R., 59, p. 477), the author found that despite the considerable differences in climate and soil, forest and other vegetation conserved water about equally well in both regions, and that it is only when the soil is bared of vegetation that erosion becomes a serious factor. Soils covered by forest are capable of absorbing water in large amounts except when frozen or covered with ice. The forested areas of southwestern Wisconsin, by actual absorption of a part of the water released about April 1 by the melting snow, helped to reduce the volume of possible floods in the Mississippi Valley.

Five-year remeasurement of sample plots, A. B. RECKNAGEL (*Jour. Forestry*, 34 (1936), No. 11, pp. 994, 995).—Measurements taken at the end of the first 5-yr. period on 20 permanent 0.25-acre circular sample plots established by Cornell University in 1931 in the Adirondacks forest area showed consistent gains in volume in all species except balsam, which suffered severe windfall losses in a July 1936 storm. In the softwood flat type the average yearly growth in cords per acre for spruce and balsam was 0.048 and 0.07, respectively. In the hardwood type the average yearly growth of spruce was 0.388 cord. In the balsam there was a net loss due to the windfall.

X-ray treatment of tree seeds, H. I. BALDWIN (*Jour. Forestry*, 34 (1936), No. 12, pp. 1069, 1070).—Dry seeds of *Pinus strobus*, *P. silvestris*, *Picea rubra*, and *P. excelsa* exposed to approximately 100 kv for exactly 4 min. at a distance of 8 in. from an X-ray tube failed to germinate appreciably different from the controls. There was indicated a slight retarding effect on the initiation of germination.

A method of studying knot formation, A. KOEHLER (*Jour. Forestry*, 34 (1936), No. 12, pp. 1062, 1063, figs. 2).—A brief description is presented of a method of sawing open the stems of second-growth trees in such a manner that a longitudinal section of every knot, even those previously overgrown, is revealed. Studies of several different species showed the need of early pruning of the lateral branches in certain trees, particularly northern white pine.

Studies in the genus *Fraxinus*.—II, Data on the flowering and fruiting habits of three American species of ash—of possible economic importance in the production of rapid-growing forest trees, E. ANDERSON and C. M. WHELDEN, JR. (*Jour. Heredity*, 27 (1936), No. 12, pp. 473, 474).—Stating that the habit of certain species to bear male and female flowers on separate trees permits the possible production of hybrid seed on an economic basis, the author presents data on the flowering and the fruiting habits of three American species and some information on pollen viability.

**Sprout groups and their relation to the oak forests of Pennsylvania, A. C. McINTYRE** (*Jour. Forestry*, 34 (1936), No. 12, pp. 1054-1058).—During the progress of a growth and yield study of oak forests by the Pennsylvania Experiment Station, data were collected in 123 sample plats on the sprouting vigor and sprout retentive capacity of the five principal oak species occurring in Pennsylvania second-growth forests. In young second-growth forests over 25 percent of the total number of stems and their basal area was found in the sprout group. As the forests grew older the number and basal area of the stems making up the sprout group was found to decrease. More sprout groups were observed on poor than on good sites. The three terms single sprout, multiple sprout, and sprout group are defined.

**The detailed structure of stem wood of the two Sequoias, J. N. MITCHELL** (*Jour. Forestry*, 34 (1936), No. 11, pp. 988-993).—Comparative anatomical studies of *Sequoia gigantea* and *S. sempervirens* failed to reveal any structural features that would serve to distinguish absolutely the two species. However, there were certain differences, the most reliable being the number of wood rays per unit area of tangential longitudinal section, *S. gigantea* on the average having 75 percent more rays than *S. sempervirens*.

**Scars resulting from glaze on woody stems, H. J. LUTZ** (*Jour. Forestry*, 34 (1936), No. 12, pp. 1038-1041, figs. 2).—A study by the Yale School of Forestry of the causes of peculiar horizontal markings on the trunks of young hardwoods led to the conclusion that scar tissue developed following lesions made during sleet storms when the trees were bent by the weight of the ice and the effect of the strong winds. Stands openly exposed to west, northwest, and north winds appeared to suffer the most injury.

**Log rules, taper tables, and volume tables for use in the South, F. J. LEMIEUX** (*Jour. Forestry*, 34 (1936), No. 11, pp. 970-974).—The author presents and discusses the functioning of tables developed and adapted for use in southern forests and which, over a period of 16 yr. of appraisal work, have proved useful in various sections of the South.

## DISEASES OF PLANTS

[Plant disease work by the Bureau of Plant Industry] (*U. S. Dept. Agr., Bur. Plant Indus. Rpt., 1936, pp. 2, 3, 5, 8, 9, 10, 12, 13, 15, 17*).—Reports are given of work on rust and smut of wheat, stalk rots of corn, "white tip" of rice, covered smut of oats, and root rot of milo and darso, and selenium toxicity to plants; control of cotton root rot; *Helminthosporium setariae* on millet and *H. turcicum* on Sudan grass; deterioration of fire-killed Douglas fir, decay in young hardwoods, and elm disease research; control of pear scab; mushroom culture and sweet orange fruit scab; nematodes attacking plants and several insects; zinc applications to the soil for control of pecan rosette; a nonparasitic disease of sugar beets; and control of tobacco blue mold by greenhouse fumigation.

[Plant disease work by the Bureau of Entomology and Plant Quarantine, 1936] (*U. S. Dept. Agr., Bur. Ent. and Plant Quar. Rpt., 1936, pp. 23-25, 37-46, 54-57*).—Reports are given of work on the control of phony peach and peach mosaic diseases; citrus canker eradication; Dutch elm disease eradication; white pine blister rust control, including the extension of the disease to northern California, protection of the western white pine area, new infection in the Lake States, the Northeastern States largely initially protected, *Ribes* eradication in the southern Appalachian region, nursery protection and cultivated black currant eradication, a summary of field operations, and the enforcement of the

quarantine; the black stem rust (wheat) quarantine enforcement; and barberry eradication.

The *Plant Disease Reporter*, November 15, December 1, and December 15, 1936 (*U. S. Dept. Agr., Bur. Plant Indus., Plant Disease Rptr.*, 20 (1936), Nos. 20, pp. 310-329, figs. 5; 21, pp. 330-339; 22, pp. 340-362, figs. 4).—Among other items of current interest, these issues contain the following notes:

No. 20.—The relative prevalence of various ear rot fungi in the 1933, 1934, and 1935 corn crops, by P. E. Hoppe and J. R. Holbert; incidence of ear rots in the 1935 corn crop, by N. E. Stevens; persistence of *Ceratostomella ulmi* in stumps of eradicated Dutch elm diseased trees in New Jersey, by T. W. Graham; miscellaneous notes on the Dutch elm disease; progress of fruit tree disease eradication campaigns (phony peach and citrus canker); strawberry dwarf in Massachusetts, by O. C. Boyd; diseases of herbaceous ornamentals in New York in 1936; by P. P. Pirone; *Septoria obesa* leaf spot of chrysanthemum, by T. B. Post; and bean rust severe in eastern Virginia and potato late blight in eastern Virginia, both by H. T. Cook.

No. 21.—Plant diseases in western Washington, by G. A. Huber; losses due to leaf roll in a potato variety test and vegetable diseases in Massachusetts in 1936, both by O. C. Boyd; two reports on downy mildews (*Peronospora trifoliorum* on alfalfa in New Mexico and *P. effusa* on spinach in tidewater Virginia, reported, respectively, by I. H. Crowell and H. T. Cook); losses from freezing and drought injury in Arkansas in 1936, by V. H. Young; and winter injury to fruit crops in Western States (report for Montana by H. E. Morris and for Idaho by E. C. Blodgett).

No. 22.—A cotton wilt survey in the Georgia Coastal Plain area in 1936, by A. L. Smith and H. W. Rankin; cotton diseases in North Carolina during the season of 1936 and root rot on peanuts in North Carolina in 1936, both by L. Shaw; occurrence of bacterial wilt in fall plantings of potatoes and eggplants in Florida, by A. H. Eddins; tomato disease notes for Georgia for 1936 (including the seedling plant industry and diseases in fields grown for fruit), by J. H. Miller; apple diseases in Pennsylvania in 1936, by R. S. Kirby, G. L. Zundel, A. H. Bauer, and L. T. Denniston; apple diseases in North Carolina in 1936, by L. Shaw; and leaf rust on Scotch pine in New York, by D. S. Welch.

[Phytopathological studies by the Arkansas Station] (*Arkansas Sta. Bul.* 337 (1936), pp. 60-64).—Progress reports not previously noted are given on a genetical, physiological, and pathological study of the cotton plant, with special reference to cotton wilt (*Fusarium vasinfectum*), by V. H. Young and L. M. Humphrey; on rice seedling blights, by E. M. Cralley; and on rose diseases, by H. R. Rosen.

[Phytopathological studies by the Delaware Station] (*Delaware Sta. Bul.* 203 (1936), pp. 37-41).—Progress reports are given on studies relating to the dissemination of peach yellows and little peach, tomato foot rot control, and the chemical disinfection of sweetpotato seedbeds, all by T. F. Manns; and to bacterial spot of stone fruits, diseases of cucurbits (downy mildew and a *Fusarium* wilt), and a comparison of spray materials for apples, all by J. F. Adams.

[Phytopathological studies by the Michigan Station] (*Michigan Sta. [Blen.] Rpt.* 1935-36, pp. 20, 21, 41).—Progress reports are given on physiological studies with virus-infected raspberries; the anthracnose of oak and sycamore; *Fusarium* yellows of celery; snapdragon rust; potato diseases (mainly *Rhizoctonia*); cereal diseases, including corn; virus diseases of peach; and materials for the control of apple scab.

[Phytopathological studies by the Missouri Station] (*Missouri Sta. Bul.* 370 (1936), pp. 29-34, 67, 88-90).—Progress reports are given of studies relat-

ing to the control of smuts on small grain, morphologic and physiologic studies of the genus *Phytophthora*, a nursery disease of sweet cherries (apparently due to *Bacterium pruni* [= *Phytomonas pruni*]), a bacterial leaf spot and canker of sweet cherries (unidentified), measles and target canker of apple trees, and identification work on plant diseases, all by O. M. Tucker; control of damping-off of seedlings, root rots of corn and other cereals, and *Fusarium* wilt of tomatoes, all by Tucker, C. G. Schmitt, and G. W. Bohn; and virus diseases of plants (including concentration of the virus), by C. G. Vinson.

[**Phytopathological studies by the New York State Station**] (*New York State Sta. Rpt. 1936*, pp. 28-35, 86, 87).—Progress reports are given of studies on scab (*Venturia inaequalis*) and cedar rust (*Gymnosporangium juniperi-virginianae*) control on apples in the Hudson Valley; the evaluation of different applications of lime-sulfur for apple scab in 1935; diseases of small fruits in western New York (raspberry mosaics and streak virus disease, and strawberry "mosaic"); diseases of canning crops (pea root rot, treating pea seed with red copper oxide-graphite, damping-off in greenhouses, defoliation of tomato plants, and fungicides for cucurbits); red copper oxide as a spray and dust fungicide; downy mildew on hops; plant disease investigations on Long Island (including the root knot nematode of potatoes, bacterial wilt of sweet corn, and potato seed treatment with yellow oxide of mercury); fungus associates of pea seed; and *Helminthosporium* spp. on barley seed.

**Department of mycology**, E. S. SALMON and W. M. WARE (*Jour. Southeast. Agr. Col., Wye, Kent, No. 37 (1936)*, pp. 15-28, figs. 2).—This gives data on the advisory and educational work of the department and progress reports on spraying tests against apple scab and on investigations of the following diseases of hops: Downy mildew (*Pseudoperonospora humuli*), virus diseases (including one believed to be new and a disease called "fluffy-tip", which is also believed to be due to a virus), canker due to *Sclerotinia sclerotiorum* (apparently a new disease of hops), a rootstock disease associated with *Marasmius rotula*, and *Cladosporium* disease. Brief miscellaneous notes are also included.

**A systematic study of plant diseases and pests, with a contribution illustrating the annual damage to agriculture done by them** [trans. title], M. GREVE (*Nord. Jordbrugsforsk., 1935*, No. 4-7, pp. 62-68).—This is a statistical summary, with discussion, of the annual losses due to various plant diseases and pests in Denmark as compared over the period 1925-31.

**Fifty years in the annals of phytopathology** [trans. title], E. GRAM (*Nord. Jordbrugsforsk., 1935*, No. 4-7, pp. 57-61).—This is a brief review of Danish work and publications relative to plant diseases for the half century beginning in 1884.

**The problem of specialization and variation in phytopathogenic fungi**, E. C. STAKMAN (*Genetica* [’s Gravenhage], 18 (1936), No. 3-4, pp. 372-389).—This contribution from the University of Minnesota and the U. S. Department of Agriculture is a general summary and critique of the present status of physiological races (particularly of the rust and smut fungi), presented at the Sixth International Botanical Congress, Amsterdam, September 2, 1935. It includes some previously unpublished data from the university and a literature list of 40 titles.

**Morphology and life history of some Ascomycetes, with special reference to the presence and function of spermatia**, III, B. B. HIGGINS (*Amer. Jour. Bot.*, 23 (1936), No. 9, pp. 598-602, figs. 13).—Continuing this series (E. S. R., 63, p. 144), this paper from the Georgia Experiment Station describes the morphology and life history of the fungus, previously known as *Cercospora liriodendri* E. and H., which causes an angular leaf spot of *Liriodendron tulipifera*.

*fera*. In addition to the conidial stage, the fungus produces spermogonia and perithecia. "The perithecial stage appears to be identical with *Sphaeria* (*Depazea*) *tulipifera* Schw., and the fungus has been transferred to the genus *Mycosphaerella* as *M. tulipiferae* (Schw.) n. comb."

"The development of both spermogonia and perithecia is initiated during the fall. The spermogonia mature and usually cease producing spermatia by the end of December, while the perithecia do not mature until the following spring.

"Evidence is presented indicating that the spermatia function as male sexual elements in the development of the perithecia."

**Studies on *Bacterium tumefaciens* in culture media**, M. LEVINE (*Amer. Jour. Bot.*, 23 (1936), No. 3, pp. 191-198, figs. 18).—Daily smears from the same culture showed morphological changes thought to be induced by the diminution in nutrients and the increase in katabolic products. The changes were not mutations, since these forms did not perpetuate themselves but appeared rather to be life-cycle phases. Irrespective of form, the organisms from old cultures transferred to fresh media always assumed the rod form characteristic of the "embryonic" stage of the species. Variations in the virulence of different cultures of the crown gall organism were noted. It is apparently capable of resisting the adverse conditions of drying and exposure to light, and in the young stages it withstood a temperature of 50° C. The sporelike bodies constantly seen in old, dry cultures are apparently an adaptive morphological change for resistance to these conditions.

Microscopic studies of Siegler's apple woolly knot organism indicated it to be unlike *B. tumefaciens* in cultural behavior. It has been shown that its pathogenic effects on stems of the common experimental plants are limited.

A contaminant, probably of the soil organisms frequently associated with *B. tumefaciens* in crown gall isolations, produces typical spores. While its tumor-inducing power leads to the conclusion that it may be slightly pathogenic, its relationship to *B. tumefaciens* is questioned.

**Further studies on the relation of the curly top virus to plant tissues**, C. W. BENNETT and K. ESAU (*Jour. Agr. Res. [U. S.]*, 53 (1936), No. 8, pp. 595-620, figs. 10).—Continuing this cooperative study by the U. S. D. A. Bureau of Plant Industry and the University of California (E. S. R., 74, p. 355), it was found that the virus invades the phloem of the entire vascular systems of beet and tobacco. In susceptible beet varieties the disease is characterized by phloem necrosis and by phloem and pericycle hypertrophy and hyperplasia. The liquid content of the phloem moves through the intercellular spaces of the extraphloem tissue and accumulates on the surface of the petioles and leaves. In resistant beets anatomical abnormalities are less extensive, and very little exudation from the phloem was observed. Phloem degeneration in diseased tobacco passes through stages similar to those observed in beet, except that the necrotic areas become cavities and are not filled by proliferation of adjacent cells. No phloem exudate was observed in the intercellular spaces outside the phloem, nor did exudate occur on the plant surface.

In resistant beets the virus content of the parenchyma of the crown and stalk and the ventral sides of the petioles was very low as compared with adjacent regions containing vascular bundles. Likewise, much less virus was obtained from wood and pith of tobacco than from bark or from tissue containing internal phloem. The virus content of immature beet seeds was very low, increasing as the seed developed to a very high concentration in the mature seed. It was most abundant in the vascular region of the seed, but may not be restricted to the phloem. No virus was recovered from the embryo. Seeds

heavily charged with virus germinated readily, and the developing embryos utilized the food stored in the perisperm without becoming infected. The virus was inactivated in dry seeds within 3 mo. Virus was recovered from the seeds, capsule wall, and placenta, and from all of the flower parts of tobacco. No virus was recovered from the pollen or from parts of the anther containing no vascular bundles.

The evidence is believed to support the concept that the virus is closely associated with the phloem of affected plants.

**The parasitism of *Penicillium rugulosum* on *Aspergillus niger*** [trans. title], A. G. ROMANKOVA (*Compt. Rend. (Dok.) Acad. Sci. U. R. S. S., n. ser., 1 (1936), No. 3, pp. 137, 138*).—The author claims to have demonstrated true parasitism of *P. rugulosum* on *A. niger*.

**The zoospores of *Phytophthora nicotianae*** [trans. title], S. KRUPKO (*Acta Soc. Bot. Polon., 11 (1934), Sup., pp. 335-400, pl. 1; Fr. abs., pp. 399, 400*).—The author describes and illustrates the morphology, cytology, development, and germination of the zoospores of *P. nicotianae*.

**Contributions on the biology of *Pseudomonas tumefaciens*** [trans. title], K. SCHILBEBSZKY (*Ztschr. Pflanzenkrank. u. Pflanzenschutz, 45 (1935), No. 3, pp. 146-159, fig. 1*).—A brief but comprehensive review of work on crown gall from its discovery in 1853 is provided, including a listing of the synonymy of the pathogen and the host families, genera, and species. In discussing the biology of the pathogen, its polyphagous and heteromorphic attacks on many dicotyledons and the nature of the resistance of monocotyledons, especially of gymnosperms, are considered. The process and effects of migration within the host tissue are also discussed. Galls caused by this pathogen are divided into eight morphological types, one of which (on *Pelargonium*) is reported for the first time. The author's inoculation work with the *Pelargonium* gall has shown *Cineraria* and *Primula* to be immune.—(*Courtesy Biol. Abs.*)

**The overwintering of *Puccinia triticina* and *P. graminis* in their uredioforms** [trans. title], K. ASPERGEE (*Ztschr. Pflanzenkrank. u. Pflanzenschutz, 45 (1935), No. 3, pp. 131-143, figs. 2*).—The author investigated the possibility of these wheat rusts overwintering in mycelial or spore stages in living or dead host tissue, *P. triticina* being used chiefly, though companion work was done with *P. graminis*. Study of natural conditions, supplemented by greenhouse and cold chamber experiments, agreed in showing that dormant mycelium is chiefly concerned in the overwintering of *P. triticina*, while *P. graminis* depends on the urediospores for its overwintering stage. It is shown that natural or artificial cold modifies the relationship of rust mycelium to host tissue, greatly prolonging latent, invisible infections when the fungus has little or no parasitic relationship to the host tissues, in contrast with the usual strictly parasitic habits of rust fungi.—(*Courtesy Biol. Abs.*)

**A method for staining rust mycelium in woody tissues**, W. G. HUTCHINSON (*Phytopathology, 26 (1936), No. 3, pp. 293, 294*).—E. Strasburger's orseilline BB-aniline blue staining procedure proved best adapted for routine examination of white pine for blister rust mycelium. The method is modified for use with freshly cut, unfixed sections. The mycelium stains violet to blue, suberized and lignified walls are red, parenchyma walls usually blue, and cytoplasm and nuclei red. Haustoria, penetrating tracheids and surrounded by lignified callosities, stain a deep red in contrast to the bluish mycelium outside the cell wall.

**A method of demonstrating rust hyphae and haustoria in unsectioned leaf tissue**, M. C. MCBRYDE (*Amer. Jour. Bot., 23 (1936), No. 10, pp. 686-688, figs. 2*).—This contribution from the Virginia Experiment Station describes a technic in which infected leaf tissue is treated in saturated aqueous solu-

tion of chloral hydrate, stained in acid fuchsin, destained in chloral hydrate, dehydrated with alcohol, counterstained with strong picric acid in oil of wintergreen, cleared in the latter, and mounted in balsam, giving clear demonstration of bean rust hyphae and haustoria.

The occurrence of *Sclerotium delphinii* Welch in Kansas, D. J. OBEH (*Kans. Acad. Sci. Trans.*, 38 (1935), p. 105).—This note reports the isolation and culture of *S. delphinii*, found parasitizing species of *Ajuga*, *Lysimachia*, and *Sedum* in a rock garden.

Studies in phanerogamic parasitism, with particular reference to *Striga lutea* Lour., I-III, A. R. SAUNDERS (*Union So. Africa Dept. Agr., Sci. Bul.* 128 (1933), pp. 56, pls. 4, figs. 3).—The following are included:

I. *The economic importance, distribution, life history, and parasitism of Striga lutea* (pp. 5-28).—Witchweed (*S. lutea*) is briefly described, and a list of its known hosts (all Gramineae) is given. The hosts exuded from their roots a substance which was necessary to the germination of the parasite, and this did not depend on the mineral nutrition of the hosts. Its action was on the cell contents of the witchweed. The absence of excessive moisture and a temperature of from 30° to 35° C. were optimum for the germination of the parasite, and there was a distinct chemotropic influence by the host roots on its developing radicle. Details of the host-parasite relations are given. Nonhosts and immune hosts may be penetrated up to a certain point, but successful parasitic relationship in them is never established. Resistance seems to be due to anatomical or protoplasmic factors, but not to the pH of the cell sap. The life cycle of the witchweed usually requires about 3 mo., but the maximum germinability is not attained until the seeds are at least 18 mo. old. Besides mineral substances, the parasite absorbs liberal amounts of assimilated food from the host and the transpiration rate of the latter is markedly reduced. A brief discussion is given of the development of parasitism in the genus *Striga*.

II. *Experiments on the control of the parasite in the field* (pp. 28-41).—Witchweed proved to be controllable by clean cultivation, but the quickest method was the planting of trap crops. Other useful methods were liberal fertilization, wide spacing, lister planting, and chlorates of sodium, magnesium, and calcium used as herbicides. Deep plowing, interplanting of cowpeas, crop rotation, and chemical treatment of the soil to destroy the seeds or seedlings proved to be of little or no advantage.

III. *The breeding of strains of sorghums and maize partially immune to witchweed* (pp. 42-54).—A number of strains of sorghum partially resistant to witchweed were found, tested on heavily infested soil, and improved by selection. Crosses were also made in an attempt to combine the resistance and the desired agronomic qualities, with promise of success.

A genetic study indicated that inheritance of resistance is very complex. Transgression appeared in all three crosses made, several segregates being much more susceptible than their susceptible parents. Susceptibility was apparently partially dominant in two crosses and resistance incompletely so in the third. Seed color and resistance segregated independently in the F<sub>1</sub>. There was no correlation in the F<sub>1</sub> between average plant height and resistance and between the yield and resistance, and in one case only was there a significant positive correlation between average plant height and yield.

Selection within self-fertilized lines of maize led to slightly increased resistance, but the results as a whole were not very encouraging.

On some species of *Ustilago* occurring on *Erianthus* and *Saccharum*, K. B. BOEDIJN (*Bul. Jard. Bot. Buitenzorg*, 3. ser., 13 (1935), No. 3, pp. 484-486).—The following species are listed and discussed as at present distinguish-

able: *U. eranthi*, *U. microthelae*, *U. pulverulenta*, *U. sacchari*, and *U. sacchariciliaris*.

The action of some aniline dyes on the development of *Narcissus tazetta* and *Phaseolus vulgaris* [trans. title], B. MANCUSO (*Riv. Biol.*, 19 (1935), No. 3, pp. 448-458, figs. 3).—The stimulatory, indifferent, and toxic effects of various dyes (fuchsin, Congo red, neutral red, methyl blue, eosin, erythrosin, and malachite green) and dosages on *N. tazetta* and *P. vulgaris* were tested and are discussed. All the dyes stained parts of the seed and seedlings, but fuchsin stained almost the whole plant.

The iron sulphate and lime-sulphur mixture as a spray, A. KELSALL (*Canad. Chem. and Metall.*, 19 (1935), No. 9, p. 239).—This is an abstract of a paper presented before the Ontario Entomological Society, November 1934, and at the Maritime Chemical Association meeting, September 1935.

Studies on barley rust (*Puccinia hordei*) [trans. title], N. F. BUCHWALD (*Nord. Jordbrugsforsk.*, 1935, No. 4-7, pp. 69-77).—A historical account of the nomenclature of *P. hordei* (= *P. anomala*) is given, followed by morphological comparisons of this species to the yellow rust fungus (*P. glumarum*), with special reference to the teliospores.

Observations on seed treatment of cereals: The toxicity of precipitated sulfur for covered smut of barley [trans. title], A. PETIT (*Rev. Path. Vég. et Ent. Agr. France*, 22 (1935), No. 1, pp. 57-59).—Precipitated sulfur is reported as effective for seed treatment of barley against covered smut (*Ustilago hordei*), though it has no action on *Tilletia*. The comparative fungicidal values of sulfur and various copper preparations against species of *Ustilago* and *Tilletia* are discussed, together with the mechanisms of their action.

Studies on the control and other aspects of bunt of wheat, C. S. HOLTON and F. D. HEALD (*Washington Sta. Bul.* 339 (1936), pp. 35, figs. 2).—Copper arsenite dust proved no more effective than copper carbonate dust in preventing bunt infection from the soil. Basic copper sulfate dust caused no seed injury to treated seed held for 1 yr., resulted in improved germination, and gave complete control in moderately smutty seed and only traces of bunt in heavily smutted seed in spring seedlings of Federation and Marquis. Holding seed treated with copper carbonate for from 3 weeks to 9 mo. before planting did not materially affect the efficiency of control in spring plantings of Federation, but did lessen the protective value of Ceresan. Fall seedlings with Hybrid 128 held for from 3 weeks to 3 mo. before planting were about equally protected, but failed of good control. Periodic seedings of heavily smutted Hybrid 128 showed decreasing effectiveness of treatments from early September to late October seedings. New Improved Ceresan at 0.5 oz. per bushel gave as good control as Ceresan at 2 oz. per bushel.

Copper carbonate did not always give equal protection with different bunt races, and poorer control followed with races of *Tilletia tritici* than with races of *T. laevis*.

Commercial washing of smutted wheat for milling purposes apparently makes it possible to clean heavily smutted grain for seed with sufficient effectiveness to use one of the standard dust disinfectants with reasonable safety.

Trench seeding as compared with normal drill seeding gave less smut in periodic plantings under natural field conditions, and in artificially contaminated soil it reduced the smut by at least one-half.

Marquis wheat obtained from different regions and uniformly smutted and planted at Pullman gave varying amounts of smut. Growing the strains there for 1 yr. made them somewhat more uniformly susceptible, while Pullman seed grown 1 yr. in other localities and returned to Pullman for seeding showed variations in the amount of smut developed.

Two new physiologic races of *T. tritici* for Washington are added to the list previously recognized. The separation of such races by criteria other than pathogenicity is discussed, and a new race of *T. tritici* is distinguished on morphological, germination, pathogenetic, and host-parasite relations. Data presented suggest that the growing of resistant varieties of wheat has tended to promote the increase and spread of new races of *T. tritici* and *T. laevis*. Variety tests have shown that the results obtained in different regions may differ, owing to the presence of different races of bunt. It is also shown that the use of composites of a large number of bunt races is not a reliable method for determining the absolute bunt resistance of a variety.

Indexes of real winter hardiness cannot be obtained from heavily smutted plantings, nor are plantings showing winter injury reliable for the determination of smut resistance.

**Experimental infection of Petkus rye with wheat bunts (*Tilletia tritici* and *T. laevis*)** [trans. title], R. NIEVES (*Bol. Min. Agr. [Argentina]*, 36 (1934), No. 4, pp. 347-359, fig. 1).—During three years (1931-33), experimental infections with these wheat bunts were obtained on the Petkus variety of rye.

**Phytopathological characteristics of the winter and spring wheat sorts in relation to smut and brand**, G. A. FRIDRIKHSO (FRIDRICHSON) (*Sotsialist. Zern. Khoz. (Socialist. Grain Farming)*, 5 (1935), No. 5, pp. 77-81; *Eng. abs.*, p. 81).—The varieties of spring and winter wheats here discussed are reported to be considerably injured by smuts, which are worst on the winter varieties. Among the spring wheats there are some varieties which escape injury and which have little or no bunt. Except for the variety *erythrospermum* [*Tritium aestivum*], these are all hard wheats.

**Experimental studies of *Penicillium* infection in wheat** [trans. title], A. NOLL (*Phytopath. Ztschr.*, 9 (1936), No. 2, pp. 147-186, figs. 6).—The paper includes a general discussion of the genus *Penicillium* and of the species found on wheat seed, the symptoms of infection, inoculation tests, the spread of the fungus within the plant, the factors influencing infection, and control measures. A literature list of 40 titles is included.

**Spotted wilt disease of lettuce and potatoes**, C. J. MAGEE (*Agr. Gaz. N. S. Wales*, 47 (1936), No. 2, pp. 99, 100, 118, figs. 4).—This virus disease, transmitted by *Thrips* spp., is stated to have been introduced into Victoria in 1915 and since to have spread to all the other Australian States. A brief general discussion, with control measures, is presented.

**Inheritance of resistance to powdery mildew in beans**, B. DUNDAS (*Hilgardia [California Sta.]*, 10 (1936), No. 8, pp. 241-253).—The susceptibility of different varieties and individual plants of *Phaseolus vulgaris* to *Erysiphe polygoni* was determined by inoculating detached leaflets on cotton soaked in 10 percent sucrose solution, the results in most cases agreeing closely with field and greenhouse infections. Mildew readings were made on the scale of 0 to 4.

The varieties Hungarian, Lady Washington, Pinto, and Pink proved resistant, while Robust and Red Kidney were susceptible under all conditions tested. Frijole negros was resistant in the field and greenhouse but semiresistant in the Petri dishes. Long Roman was semiresistant in the field and greenhouse but susceptible in the dishes. Plants were often somewhat more resistant in the seedling stage than later.

"The  $F_1$ ,  $F_2$ , and  $F_3$  progenies of a cross between the semiresistant Long Roman and the resistant Pinto were similarly tested, and of the 47 resistant  $F_1$  plants tested 16 proved to be homozygous and 31 heterozygous. Readings of 0 and  $t$  [trace] in the  $F_2$  plants indicated homozygosity or heterozygosity for resistance; 1 and 2, heterozygosity only; and 3 and 4, homozygosity for sus-

ceptibility. In the crosses with Robust and Long Roman, the Pinto is seen to have a single Mendelian factor pair for resistance to the strain of powdery mildew used."

**Snowmold injury to bent grasses**, J. TYSON (*Michigan Sta. Quart. Bul.*, 19 (1936), No. 2, pp. 87-92, figs. 7).—On the basis of the 1935-36 results, the author discusses and copiously illustrates the relative susceptibility and resistance of various strains of bentgrass to snow mold injury, the decreasing resistance rating of the varieties used being Astoria Colonial, Washington, and Metropolitan creeping, Rhode Island and Prince Edward Island Colonial, German mixed, and Seaside creeping bentgrasses.

Injury on plats treated continuously with organic fertilizers, such as cottonseed meal, dried blood, or millorganite, was much more severe than on those treated with ammonium sulfate, urea, or sodium nitrate. Injury was least with calcium nitrate.

Good results were obtained with all mercury treatments used, their relative effectiveness depending on their mercury content. Best results followed mixing with dry soil and broadcasting without subsequent watering.

**Principal diseases of cotton in Peru** [trans. title], G. GARCIA RADA (*Min. Fomento, Dir. Agr. y Ganaderia [Peru], Circ.* 28 (1935), pp. 19, pls. 6, figs. 5).—The cotton diseases included in this handbook are wilt (*Fusarium vasinfectum*), sore shin or damping-off (*Rhizoctonia* sp.), powdery mildew (*Erysiphe malachrae*, conidial stage *Ovulariopsis gossypii*), brown boll spot (*Helminthosporium gossypii*), and black leaf spot (*Alternaria tenuis*). All are illustrated by colored plates.

**Note on the Diplodia of cotton** [trans. title], N. AZEVEDO (*Rodriguésia*, 1 (1935), No. 2, pp. 97, 98, fig. 1).—This is a note on a *Diplodia* occurring on cotton bolls in Brazil, having the characteristics of *D. gossypina*.

**A rating of plants with reference to their relative resistance or susceptibility to Phymatotrichum root rot**, J. J. TAUBENHAUS and W. N. EZEKIEL (*Texas Sta. Bul.* 527 (1936), pp. 52).—The ratings given are based either on artificial inoculations in experimental fields or on field observations over a period of years. The 2,116 plants listed include the crop plants widely grown in root rot areas, native weeds, shrubs, and trees, and also some less common plants. The general basis for the ratings is the percentage of plants which develop symptoms of root rot when exposed to infection under favorable conditions, and the relative susceptibility is indicated by symbols. Table 1 summarizes the relative susceptibility or resistance by families, while table 2 gives similar data for the plant species arranged alphabetically by scientific names under their respective families. An alphabetical index gives a key to the lists through both the common and generic names of the plants included.

**Chemical dust treatment of cottonseed for planting purposes**, H. P. SMITH, D. L. JONES, D. T. KILLOUGH, and H. C. McNAMARA (*Texas Sta. Bul.* 531 (1936), pp. 24).—At all locations used, when planted at optimum rates and dates, fuzzy cottonseed treated with Ceresan gave an increase both in number of seedlings and in yield. At Lubbock, the early planted Ceresan-treated fuzzy seed gave fewer seedlings and lower germination than the untreated seed but no significant differences in yield. Ceresan treatment of mechanically delinted seed planted at optimum rates and dates gave a larger number of seedlings emerging at four of the stations than no treatment. At Greenville, seedlings from seed treated with Ceresan or Bayer Dust 502 and delinted with HCl gas or H<sub>2</sub>SO<sub>4</sub> had a smaller number of plants infected with angular leaf spot in the early seedling stage. Treating fuzzy seed with Bayer Dust over a 3-yr. period gave fewer seedlings but slightly higher yields than did untreated seed, while similar treatment of mechanically delinted seed gave more seedlings but slightly

lower yields. Treatment of fuzzy or mechanically delinted seed with copper carbonate was unsuccessful under Lubbock conditions.

When cotton was planted at Lubbock on four dates within the month beginning April 25, the total number of plants generally increased the later the date of planting. When untreated fuzzy seed was planted at the rates of 16, 20, 24, 28, and 32 lb. per acre at four stations, there was a general tendency for the stands at thinning time to be larger as the rate of planting increased. In most cases untreated seed planted in a 4-in. listed furrow averaged more plants than either surface planting or the 7-in. listed furrow at Lubbock. Thinning at Lubbock to a 12-in. spacing gave a higher yield than unthinned cotton for both treated and untreated fuzzy or delinted seed.

**Biometrical study of the spores of *Phlyctaena ? linicola*** [trans. title], L. A. GABASSINI (*Rev. Argentina Agron.*, 2 (1935), No. 7, pp. 245-249, fig. 1).—The author presents statistical data on the spore measurements of this fungus as grown on various natural and artificial culture media, and concludes from this preliminary study that the fungus of flax pasmo should be transferred to *Septoria* or to some related genus.

**Resistance of *Nicotiana* species to blue mould (*Peronospora tabacina* Adam)**, S. SMITH-WHITE, S. L. MACINDOE, and W. T. ATKINSON (*Jour. Austral. Inst. Agr. Sci.*, 2 (1936), No. 1, pp. 26-29).—Tests of varieties of *N. tabacum* and *N. rustica* indicated little of value for breeding for resistance, but high resistance was found in the Australian species. Some of the latter, and particularly *N. debneyi*, may prove valuable for breeding. It is suggested that their high resistance may be significant as indicating the possible origin of *P. tabacina*.

**Paspalum ergot**, R. B. MORWOOD (*Queensland Agr. Jour.*, 45 (1936), No. 2, pp. 146, 147, fig. 1).—This is a general note on *Claviceps paspali* as it occurs on this popular pasture grass in Queensland.

**Curly dwarf in Colorado**, C. H. METZGER (*Amer. Potato Jour.*, 13 (1936), No. 11, pp. 316, 317).—A serious disorder of Brown Beauty potatoes is described. The symptoms resemble those described by Orton (*E. S. R.*, 30, p. 649) for curly dwarf. First observed on occasional plants in 1933, it was much more prevalent in 1935. Further studies by the Colorado State College were under way to determine whether it is a virosis, as is deemed probable.

**Some observations on potato "degeneration" in South Africa**, A. R. PULLEN and J. WASSERMANN (*So. African Jour. Sci.*, 32 (1935), pp. 271-279, pl. 1).—Potato deterioration in South Africa is common, but examination of potato fields in the Transvaal has shown that virus diseases may be far less prevalent than would be expected. Descriptions are given of abnormal forms suspected of virus origin, and some of them are said to agree closely in symptomatology with virus diseases described in other countries.

"The prevalence of what are locally called 'wild' potatoes in potato fields is commented on, and descriptions of two distinct types are given. They are considered to be true rogues and not systemic virus-diseased plants. They appear healthy, and one of them breeds true from seed harvested from berries. . . . The sorting out of seed-size tubers from the heap after harvesting—without discrimination against the wild form insures the perpetuation of the latter at the expense of the true variety.

"It is suggested that good stocks of potato seed can be maintained in South Africa by careful selection of seed, followed by hill selection of healthy, normal plants. Fields used for planting should be clean, i. e., free from rogues."

**Breeding for resistance to common scab in the potato**, C. F. CLARK, W. P. RALEIGH, and F. J. STEVENSON (*Amer. Potato Jour.*, 13 (1936), No. 9, pp. 256-259).—The results are reported of tests begun in 1930 in cooperation with the

Maine Experiment Station to determine the resistance to [*Actinomyces scabies*] of some thirty-four European and American potato varieties, as well as many South American types, seedlings, and progenies from various crosses. Promising evidence of scab resistance (though never complete immunity) was met with in both russet and smooth-skinned types.

**Fungi isolated from discolored rice kernels**, E. C. TULLIS (*U. S. Dept. Agr., Tech. Bul. 540 (1936), pp. 12, figs. 4*).—In studies in cooperation with the Arkansas, Louisiana, and Texas Experiment Stations, the discoloration of rice kernels seemed to be due to several fungus species, and 16 genera have been isolated from surface-sterilized kernels. The parasitic forms gain entrance through the glumes and attack the immature kernel, while the saprophytic forms may develop after the rice matures.

In descending order of relative frequency of occurrence, the fungi most commonly found are as follows: *Curvularia lunata*, *Fusarium* spp., *Trichoconis caudata*, *Helminthosporium oryzae*, *Phoma* spp., *Alternaria* spp., *Cladosporium herbarum*, *Nigrospora oryzae*, *Curvularia maculans*, *Epicoccum neglectum*, and *Helicocercus oryzae*.

**Observations on the occurrence of *Anguillulina dipsaci* (Kühn, 1858) on rhubarb in Yorkshire**, L. R. JOHNSON (*Jour. Helminthol.*, 14 (1936), No. 2, pp. 77-84, figs. 3).—The history of the infestation in Yorkshire, where it is widespread and always intimately associated with crown rot, is reviewed.

In the present study, active eelworm infestation was always seen in advance of severe rotting, and all the data strongly suggested that it is of primary importance in the development of the decay. Factors influencing eelworm infestation in rhubarb are discussed, including soil type, cultural methods, disposal of debris, and rotations. Infection tests provided additional evidence to the field observations that the oat and rhubarb strains of *A. dipsaci* are reciprocally infective. From all data at hand, it appears safest to assume that, although bacteria alone can cause crown rot, in the field the incidence of the disease is increased very considerably by eelworm attack which is always present in advance of the bacterial rotting. With healthy rootstocks and lack of eelworm infestation in the field, the disease appears to be largely controlled.

**The pH gradient extending from the phloem into the parenchyma of the sugar beet and its relation to the feeding behavior of *Eutettix tenellus***, J. M. FIFE and V. L. FRAMPTON (*Jour. Agr. Res. [U. S.]*, 53 (1936), No. 8, pp. 581-593, figs. 4).—When treated before and during the inoculating period, the ratio of curly top infection in normal v. CO<sub>2</sub>-treated seedlings was 4.7:1. Exposure of seedlings to high concentrations of CO<sub>2</sub> immediately after inoculation failed to reduce the percentage of infection. When the vector *E. tenellus* is forced to feed on the petioles of plants treated with CO<sub>2</sub>, it apparently loses its sense of direction, so that reaching the phloem, from which it normally feeds, becomes a matter of chance. Of the feeding tests in the normal petioles, 56 percent terminated in the phloem, whereas only 12 percent of the tests in the CO<sub>2</sub>-treated petioles terminated there. The ratio was 4.6:1. The striking agreement between these two ratios is further evidence that the virus must be deposited in the phloem to induce infection.

A microquinhydrone electrode was built in such a way that the pH of the individual parenchyma cells could be measured without disturbing adjoining cells. A gradual pH gradient from the phloem into the parenchyma was found in the normal sugar beet petioles. By exposing them to high concentrations of CO<sub>2</sub>, the normal pH gradient was entirely upset and even reversed. The pH gradient in the CO<sub>2</sub>-treated petioles returned to normal when placed under atmospheric conditions. The evidence thus indicates that the leafhoppers, while feeding under normal conditions, are guided to the phloem by the pH gradient.

**Comparison of derivatives from distinctive strains of tobacco-mosaic virus.** F. O. HOLMES (*Phytopathology*, 26 (1936), No. 9, pp. 896-904, fig. 1).—"Yellow-mosaic strains derived from the masked strain of tobacco-mosaic virus, although not confined to primary lesions, were found characteristically to lack the high degree of invasiveness possessed by many yellow-mosaic strains derived directly from the distorting strain of tobacco-mosaic virus. The uninvasive character that was obtained at the time of isolation of the masked strain was thus retained in the systemic yellow-type derivatives of this strain. Changes to yellow-mosaic type and to invasive type appear to be independent and may represent unit differences in the structure of the virus similar to unit differences in genetic structures of plants and animals."

**Possible relationship of Stanley's crystalline tobacco-mosaic-virus material to intracellular inclusions present in virus infected cells.** H. P. BEALE (*Contrib. Boyce Thompson Inst.*, 8 (1936), No. 4, p. 333).—This is an abstract of a paper presented before The American Phytopathological Society, December 29, 1936, in which studies were described showing that under the influence of HCl crystalline plates in the cells of six different host plants affected with Johnson's tobacco virus 1 or 6 disintegrated into needle crystals indistinguishable from those formed by acidification of the virus extract purified according to the Stanley method (*E. S. R.*, 73, p. 800).

**Inactivation of tobacco mosaic virus by ascorbic acid.** M. LOJNIN (*Contrib. Boyce Thompson Inst.*, 8 (1936), No. 4, p. 335).—This is an abstract of a paper presented before The American Phytopathological Society, December 29, 1936, describing studies in which the reduced form of ascorbic acid as dilute as 0.03 mg per cubic centimeter completely inactivated purified tobacco-mosaic virus in the presence of atmospheric oxygen.

**Inactivation of the virus of common tobacco mosaic by drying and by freezing in soil.** S. G. LEHMAN (*Jour. Elisha Mitchell Sci. Soc.*, 52 (1936), No. 2, p. 159).—An abstract.

**Carbolineum emulsions for orchard trees.**—I, The stability and dispersion of carbolineum emulsions [trans. title], F. BERAN (*Anz. Schädlingssk.*, 12 (1936), No. 2, pp. 17-22, figs. 2).—This study indicated that the stability of carbolineum emulsions in containers is no criterion of their permanence as emulsion films.

**Chlorosis of fruit plants and methods for controlling it.** S. F. V'YUNOV (VYUNOFF) (*Nauch. Plodovod. [Michurinsk]*, No. 6 (1935), pp. 12-32; *Ing. abs.*, pp. 31, 32).—Insufficient absorption of iron by the roots is given as the main, direct cause of chlorosis on carbonate soils, one of the indirect causes being calcium carbonate in the precipitated form. The physiological activity of the roots also has its influence, acid excretions aiding in the absorption of iron. Palliative control methods are recommended, including iron or sulfur applications, breeding of chlorosis-resistant stock, and avoidance of the type of carbonate soils favoring chlorosis.

**Fire blight: Overwintering, dissemination, and control of the pathogene.** K. G. PARKER ([New York] *Cornell Sta. Mem.* 193 (1936), pp. 42, figs. 5).—Fire blight ooze infecting the first spring blossoms may originate from overwintering cankers on twigs, but this does not appear to be very common in the average New York season. Blight infections usually can be traced to larger overwintering cankers within the orchard. Dissemination of primary inoculum to the blossoms may be effected by splashing rain, if the source is in the upper part of the tree. Insect transmission is well known, and experimental evidence is presented incriminating species of flies and ants. Evaluation of the relative importance of rain and insects is not attempted on the evidence available. Dissemination of secondary inoculum to blossoms may be effected to a small

extent by meteoric water, though blossom-visiting insects are probably more important in transmission from blossom to blossom. Inoculation of growing shoots and leaves may be primary or secondary. Sucking insects seem to be relatively important in infecting terminals, but rain may be a factor here also. Leaves are inoculated by both insects and rain.

Bacteria antagonistic to *Erwinia amylovora* [= *Bacillus amylovorus*] in culture have been found which will to some extent prevent blossom infection, or even inhibit an infection already started.

Zinc chloride solutions of sufficient concentration to disinfect the cankers killed more of the living bark than was desirable, but cadmium sulfate solutions possessed considerable efficiency in disinfecting them without serious injury to the sound tissues.

**A disease of pear trees due to a basidiomycete** [trans. title], G. GOUDANCH (Bol. R. Staz. Patol. Veg. [Roma], n. ser., 15 (1935), No. 4, pp. 501-532, figs. 13).—This disease, shown to be due to *Stereum purpureum*, is described as to both internal and external symptoms, and the morphology and behavior of the fungus (on media and on the host) and the host-parasite relations are detailed. Control measures are suggested.

**Symptomatic and etiologic relations of the canker and the blossom blast of Pyrus and the bacterial canker of Prunus**, F. E. WILSON (Hilgardia [California Sta.], 10 (1936), No. 8, pp. 213-240, figs. 6).—The main object of this study was to determine the relationships between a canker and blossom blast of pear and the bacterial canker of stone-fruit trees. The results indicated that the limb canker and blossom blast of pear are phases of the same disease, which also attacks dormant buds, twigs, and fruits. The pear and stone-fruit diseases showed similarities as to the parts attacked, the character of the symptoms, and the season of activity, and the bacteria from the two hosts were identical in the inoculation and cultural tests.

Besides the two strains of stone-fruit bacteria (*Phytomonas* [= *Bacterium*] *cerasi* and *P. cerasi prunicola*) and those from pear limb cankers and blossom blast, the pathogenicity and cultural studies included also *P. utiformica*, *P. papulans*, *P. citriputale*, cultures isolated by H. R. Rosen from pear blossom in Arkansas, and cultures isolated by the author from apple in California. These inoculation and cultural studies supported the belief that *P. utiformica*, *P. citriputale*, and Rosen's bacterium are identical with the stone-fruit organism, while *P. papulans* proved to be an unrelated species. Except for the last, the author believes that these organisms should be given the same species name and that the preponderance of evidence from the literature points toward *P. syringae* as the correct binomial.

*Erwinia amylovora* [= *Bacillus amylovorus*] was differentiated from the canker organisms described.

**Green rotting of apricot fruits and dying back of apricot branches caused by Sclerotinia sclerotiorum** [trans. title], S. J. DU PLESSIS (So. African Jour. Sci., 32 (1935), pp. 233-245, figs. 5).—*S. sclerotiorum* was isolated from affected material in the Stellenbosch region of South Africa, and the symptoms and histopathology of the disease are discussed. A *Botrytis* sp., associated with the green rotted fruits, proved to be a saprophyte or at most a secondary parasite.

**Peach mosaic not cured by heat treatments**, L. O. KUNKEL (Amer. Jour. Bot., 23 (1936), No. 10, pp. 683-686, fig. 1).—Experiments were conducted with peach material from Colorado affected by a form of mosaic, the symptoms of which, as developed in young trees in the greenhouse, are described. Transmission by juice inoculations failed, by budding succeeded. Hot-room treatments effective in curing peach trees of yellows, rosette, little peach, and red

suture failed to inactivate this mosaic virus. In bud sticks it was not inactivated at 35°, 42°, or 50° C. for periods of time nearly as long as the limit at which peach tissues could remain alive. It seemed doubtful that heat treatments would prove effective in dealing with this mosaic, which does not appear closely related to the other viruses mentioned.

**Copper sulfate and lime-sulfur** [trans. title], A. PIERI (*Note Fruttic.*, 14 (1936), No. 1, pp. 3-7).—This note discusses the comparative merits of these salts in fungicidal sprays against *Euxoascus* infection of peach trees.

**The *Cercospora* species parasitizing grape leaves in Palestine** [trans. title], T. SAVULESCU and T. RAYSS (*Rev. Path. Vég. et Ent. Agr. France*, 22 (1935), No. 3, pp. 222-241, pls. 6).—Six species from grape leaves are described (four in Palestine), of which *C. leoni* and *C. corymbodora* are new. Five species are illustrated.

**Chlorosis of grapevines** [trans. title], L. CASALE (*Ricerca Sci. [Roma]*, 2 (1935), No. 11-12, pp. 440-443).—The author presents experimental data, in part from his published work, on the relation of soil reaction and composition to grape chlorosis.

**Excoriosis and copper dusts** [trans. title], M. BIRON (*Rev. Vitic.*, 84 (1936), No. 2168, pp. 42-45).—Observations are given on the symptoms and course of excoriosis of grapevines due to *Phoma flaccida*, on the injuries caused, and on sanitary, cultural, and fungicidal methods of reducing the inroads from the disease. The author's experiences with fungicides are briefly summarized, and special emphasis is given to the copper dust treatments which have been shown to offer an effective means of control.

**Studies on the wastage of export grapes, with special reference to that caused by *Botrytis cinerea*, Pers.**, S. J. DU PLESSIS (*Union So. Africa Dept. Agr. and Forestry, Sci. Bul.* 151 (1936), pp. 163, pls. 7, figs. 16; *Dutch abs.*, pp. 147-150).—This monograph gives special attention to the wastage due to *B. cinerea*, but the types of injury caused by nine other fungi are described. Comparative studies were made of seven monospore isolations of *B. cinerea* from grape, pear, apple, and quince (including cultural, morphological, fungicidal, and pathogenicity comparisons); field studies of wastage, including influencing factors (mechanical injuries, time of picking, fertilizers, etc.); and tests of various control measures. Formaldehyde gas fumigation yielded promising results, but some injury was caused. Satisfactory control followed spraying the bunches or wrappers with a 4-percent solution of formaldehyde in water, and particularly good results were obtained from a moderate spraying of the wood wool linings of the boxes. Ripe or overripe grapes proved much more susceptible to the storage rots than those in a greener condition.

A bibliography of 123 titles is included.

**False mildew of red mulberry**, F. A. WOLF (*Mycologia*, 28 (1936), No. 2, pp. 268-277, figs. 3).—The developmental morphology of a pleomorphic fungus, *Cercosporella arachnoidea* n. sp., is described. The conidial stage imparts the gross appearance of a powdery mildew on the foliage. At the time of leaf abscission in the fall the lesions are occupied by spermatogonia and perithecial primordia. The perithecial stage matures in the spring and is here described as *Mycosphaerella arachnoidea* n. sp.

**Notes on the strawberry strains of the bud and leaf nematode, *Aphelenchoides fragariae***, I. J. R. CHRISTIE and L. CROSSMAN (*Helminthol. Soc. Wash. Proc.*, 3 (1936), No. 2, pp. 69-72, fig. 1).—This article describes methods of artificially infesting strawberries, methods of rearing the strawberry strain by providing a growth of *Alternaria citri* on agar as a source of nutriment, injury from the treatment of strawberry plants with hot water, and the method

of differentiating the eggs of different nematodes frequently found on strawberries.

**Citrus diseases and their control**, H. S. FAWCETT (*New York and London: McGraw-Hill Book Co., 1936, 2. ed., rev., pp. XV+656, figs. 187*).—This is a "completely revised, rewritten, and enlarged" edition of the work previously reviewed (E. S. R., 56, p. 751). "A number of new sections have been added, such as mal secco, water rot, areolate spot, bark blotch, sweet orange fruit scab, Australian citrus scab, Valencia rind spot, rind break-down, *Clitocybe* root rot, hard root rot, *Macrophomina* root rot, infectious mottling, zonate chlorosis, *Ascochyta* blight, cotton root rot, red root disease, *Ganoderma* root rot, xyloporosis, little leaf, mesophyll collapse, bordeaux injury, and new minor rots and effects. A new chapter on diseases due to deficiency and excess of inorganic constituents was written in collaboration with Dr. A. R. C. Haas. The new sections on sweet orange fruit scab, Australian citrus scab, and areolate spot were written in collaboration with Dr. Anna E. Jenkins, and the section on citrus blight in collaboration with Dr. A. S. Rhoads."

**Elsinoe fawcetti, the perfect stage of the citrus scab fungus**, A. A. BITAN-COURT and A. E. JENKINS (*Phytopathology*, 26 (1936), No. 4, pp. 393-396, fig. 1).—The perfect stage of the citrus scab fungus (*Sphaceloma fawcetti*) is reported from the rind of the Satsuma orange (*Citrus nobilis unshiu*) in São Paulo and is described as *E. fawcetti* n. sp.

**The entomogenous fungi of citrus** [trans. title], R. BENATAR (*Rodriguésia*, 1 (1935), No. 2, pp. 7-10, fig. 1).—This note includes species of *Aschersonia*, *Podonectria*, *Sphaerostilbe*, *Septobasidium*, *Myriangium*, etc.

**Die-back of coffee** [trans. title], H. J. DE FLUITER (*Alg. Landb. Weekbl. Nederland. Indic.*, 20 (1935), No. 2, pp. 34-36).—This is a report from the Besoeki Experiment Station, describing the disease as it occurs in the Dutch East Indies and suggesting methods of control.

**An anthracnose of hwangpsee, *Clausena lansium* (Lour.) Skeels**, in South China, L. Y. LI (*Lingnan Sci. Jour.*, 15 (1936), No. 1, pp. 113-117, fig. 1; *Chin. obs.*, p. 117).—A serious disease of the fruits of *C. lansium* was found to be due, at least in part, to *Gloeosporium* sp., and successful inoculations were also made on fruits of papaya, banana, pepper, chu sha kat (*Citrus erythrosa*), orange, lemon, guava, carambola (*Averrhoa carambola*), Chinese olive, roselle, avocado, sha lei (sand pear), and sugar-apple (*Anona squamosa*) with spores from pure cultures of the fungus obtained from affected fruits of hwangpsee. The fungus appeared to be closely related to the *Gloeosporium* stage of *Glomerella cingulata*.

**A bacillus isolated from diseased plants of *Aucuba japonica* (Thunb.)**, G. TRAPP (*Phytopathology*, 26 (1936), No. 3, pp. 257-265, fig. 1).—The Japan laurel (*A. japonica*) is subject to a blight characterized principally by die-back of twigs, and hitherto unrecorded. From the more recently necrosed portions of affected plants, *Pseudomonas aucubicola* n. sp. was consistently isolated in pure culture. Since inoculations of healthy *Aucuba* tissues with recently isolated, vigorous subcultures failed to establish its pathogenicity, the organism must be classed, at least provisionally, as a saprophyte of special habitat.

**A mosaic disease of iris**, P. BRIKLEY and F. P. McWHORTER (*Jour. Agr. Res.* [U. S.], 53 (1936), No. 8, pp. 621-635, figs. 4).—This reports a cooperative study by the Oregon Experiment Station and the U. S. D. A. Bureau of Plant Industry, dealing chiefly with bulbous iris. The symptoms included general dwarfing, mosaic mottling of leaves, and "breaking" of flowers, though the last was not always expressed. Variations in degree of mottling and dwarfing occurred. In mosaic leaves the size of the epidermal cells was reduced, and X-bodies of vacuolate or reticulate types were sometimes present. The number of plastids was reduced in flecked areas of affected flowers.

The virus was transmissible through a wedge of diseased stem tissues or injection of diseased juice by hypodermic needle. The multiple-needle method and rubbing with virus-bearing juice proved ineffective. Plants inoculated in one growing season showed symptoms the following season. Field-cage experiments showed *Illinoia solanifolia* and *Myzus persicae* to be vectors, but three other aphid species failed to transmit. The vectors were more efficient when migrating naturally than when manually transferred.

Cross-inoculations between varieties of Dutch and Spanish iris were readily successful. Mosaic was transmitted to bulbous iris from naturally infected *Iris ricardi*, from *I. unguicularis alba*, and from the bearded iris William Mohr. No hosts were found outside the genus.

**Spotted wilt of the sweet pea**, W. C. SNYDER and H. R. THOMAS (*Hilgardia* [California Sta.], 10 (1936), No. 8, pp. 255-262, fig. 1).—The virus of this disease of *Lathyrus odoratus* has been proved identical with that causing spotted wilt of tomato, and it has been recently reported as causing a streak disease of garden peas. The symptoms of the disease and inoculation experiments are detailed. The disease is a serious factor in certain coastal districts of California and is often complicated by mixtures with mosaic viruses. The large number of susceptible hosts increases the seriousness of the problem.

By mechanical inoculations and cross-inoculations, symptoms typical of spotted wilt of tomato and streak of sweet pea were induced irrespective of the virus source. Furthermore, with the juice from a streak disease of garden peas, spotted wilt symptoms were obtained on *Nicotiana glutinosa* and *N. tabacum*, and also 2 out of 18 inoculated sweet pea plants developed streak. These and similar data confirmed the conclusion that these viruses are identical.

Transmission of the spotted wilt virus to sweet pea was also obtained by means of *Thrips tabaci*. The virus may be separated from the mosaic viruses through differential hosts, but, since *Macrosiphum pisi* is not a vector of the spotted wilt virus, this insect may be used to isolate the mosaic virus where both are present in the same plant.

Control of the sweet pea disease appears to lie in the isolation of plantings from other susceptible crops or in protection against the migrations of infective thrips.

**The black rot of chestnut fruits due to *Sclerotinia pseudo-tuberosa*** [trans. title], G. ARNAUD and J. BARTHELET (*Compt. Rend. Acad. Agr. France*, 22 (1936), No. 2, pp. 48-51).—This disease, "known from time immemorial in France and neighboring lands", is reported to be a serious menace to the culture and commerce of chestnuts. The symptoms, nomenclature of the causal fungus, time of infection, and various local observations are discussed briefly. As far as present knowledge can be generalized, it is concluded that the best means of avoiding the injuries is to harvest the nuts as soon as they fall and to keep them in a cold, humid place.

**Researches on the preservation of chestnuts from molds by disinfection with water at 50° C. for 45 minutes** [trans. title], O. SERVAZZI (*Bol. Lab. Sper. e R. Osserv. Fitopat.* [Torino], 30 (1935), No. 6, pp. 191-203).—This reports tests with hot water and fungicidal treatments of chestnuts against molds.

**Dutch elm disease, *Graphium ulmi***, G. P. CLINTON and F. A. McCORMICK (*Connecticut* [New Haven] *Sta. Bul.* 389 (1936), pp. 697-752, pls. 8).—The discovery of this disease, the recorded spread and extent of damage in Europe and America, and the control work carried on are historically reviewed, and the results of research on the disease and on the causal organism, *Ceratostomella ulmi*, are summarized with special reports on the field and laboratory studies in Connecticut.

**Ceratostomella piceae, the cause of the blue stain on pine** [trans. title], Y. NISIKADO and K. YAMAUTI (*Bot. and Zool. [Tokyo]*, 3 (1935), No. 2, pp. 365-376, figs. 6).—The literature on this and related fungi is briefly reviewed, the injury is discussed, and the morphology and life history of the fungus and the host-parasite relations are described, all in Japanese.

**Effects of pruning the roots of gas-injured trees**, C. G. DEUBER (*Amer. Jour. Bot.*, 23 (1936), No. 6, pp. 432, 433).—Injury to roots, buds, and foliage occurred within 6 weeks after the roots of small oak trees were placed in water into which measured volumes of illuminating gas were passed. Though root decay was checked and new branch roots were formed in one lot where the root ends were pruned before repotting in soil, the tops of such trees showed no improvement over the controls in 2 yr.

**Forest fire damage studies in the Northeast.—III, Relation between fire injury and fungal infection**, P. W. STICKEL and H. F. MARCO (*Jour. Forestry*, 34 (1936), No. 4, pp. 420-423, fig. 1).—Continuing this series (*E. S. R.*, 73, p. 485), "observations on burned-over areas show that in northeastern forests between 28 and 45 percent of fire-scarred live trees become infected with fungi, causing decay of the sapwood within 3 yr. after burning. In northeastern hardwood stands, where merchantable values are so largely confined to butt logs, the presence of decay at the base is especially serious. The rapidity with which these sapwood rots infect the damaged live trees after fire indicates the necessity for early salvage cuttings if deterioration of such trees is to be prevented."

**Testing methods for protecting wood against fungus invasion, I** [trans. title], W. RAVENDAMM (*Angew. Bot.*, 18 (1936), No. 2, pp. 132-141, figs. 3).—This paper is the first on a series of studies of methods and results of wood impregnation with chemical preparations to prevent decay from fungus invasion. It has special reference to two proprietary preparations, "Basilit-U" (with sodium fluoride and a dinitrophenol compound as chief constituents) and "Fluralsil-Extra" (principally zinc fluosilicate), and a third material of unknown composition. The wood-block method was used in testing these materials against *Merulius tachrymans*, *Coniophora cerebella*, and *Polyporus vaporarius*, with promising results.

**On the classification of the Tylenchinae**, I. N. FILIPJEV (*Helminthol. Soc. Wash. Proc.*, 3 (1936), No. 2, pp. 80-82).—A key is given, with descriptions, as a basis for a new organization of related genera. Eighteen genera are included as follows: *Rotylenchus*, *Hoplolaimus*, *Pratylenchus*, *Tylenchorhynchus*, *Chitinylenchus*, *Dolichodoros*, *Tetylenchus* n. g., *Halenchus*, *Psilenchus*, *Eutylenchus*, *Ditylenchus*, *Anguina*, *Iotonchium*, *Neotylenchus*, *Hecatyplus*, *Hemicyclophora*, *Macroposthonia*, and *Eophyadophora*.

**The status of the nematode *Aphelenchus avenae* Bastian, 1865, as a plant parasite**, G. STEINER (*Phytopathology*, 26 (1936), No. 3, pp. 294, 295, fig. 1).—Although living chiefly as a saprophyte and most frequently associated with decayed or diseased material, *A. avenae* has been observed in the parenchyma of a hybrid phlox root together with recently deposited eggs, proving that this nematode is also able to sustain life in healthy plant tissue. This form must therefore be considered as a facultative plant parasite with perhaps dominant, necrobiotic food tendencies.—(*Courtesy Biol. Abs.*)

**A new species of *Stylopaga* preying on nematodes**, C. DRECHSLER (*Mycologia*, 28 (1936), No. 3, pp. 241-246, fig. 1).—*S. leiohypha* n. sp., a fungus here described, was found in the soil, near Sanford, Fla., capturing and consuming nematodes up to 0.25 mm long and belonging to species of *Rhabditis*, *Cephalobus*, and *Acrobeles*.

**ECONOMIC ZOOLOGY—ENTOMOLOGY**

**Wildlife Review**, [December 1936] (*U. S. Dept. Agr., Bur. Biol. Survey, Wildlife Rev. No. 7 (1936), pp. 50*).—The present number includes, in addition to the usual abstracts, author and subject indexes to the first seven numbers (*E. S. R.*, 76, p. 355).

**Animal life in Palestine: An introduction to the problems of animal ecology and zoogeography**, F. S. BODENHEIMER (*Jerusalem: L. Mayer, 1935, pp. [8]+506, figs. [147]*).—The first and general part of this work (pp. 1-90) takes up the history of zoological exploration, the zoogeographical position, history of animal life, and general ecology of animal life in Palestine. Accounts of the mammals, bird life, reptiles and amphibia, insect life, other terrestrial animals, fresh water hydrobiology, and animal life on marine shores follow. Author and animal indexes are included.

**Banding studies of semidomesticated mallard ducks**, P. L. FERRINGTON and W. E. ALBERT, JR. (*Bird-Banding, 7 (1936), No. 2, pp. 69-73*).—Contributing from the Iowa Experiment Station, a report is made of the behavior of several hundred mallard ducks of all degrees of domestication that were released upon discontinuation in 1932 of a State game farm at Lansing, Iowa.

The majority of the data presented are nearly equally divisible into four chief categories. "A little over one-fourth of the 350 birds banded while young remained regular local residents until the second summer following. A little less than one-fourth remained until the first summer before they were lost track of; a similar number were recorded no later than the fall following banding. Almost exactly one-fourth were never retrapped nor heard of again. . . .

"The preponderance of the birds which have disappeared, we may suppose, are either dead or are living elsewhere. Numbers of those which have disappeared from the immediate area may be living somewhere, but the very low percentage of returns from birds shot by hunters (two-season total of 0.9 percent compared to Lincoln's [*E. S. R.*, 72, p. 72] 12 percent first-season expectation for wild birds) does not indicate that very many have fully reverted to the wild state. It is significant to note that despite the immaturity of these birds at banding, three-quarters were known to have attained December size.

"One reasonable supposition is, if the records of the missing birds have not been terminated by death, that at least some of them have migrated only to establish themselves en route on refuges on which they have found things to their liking. The corn and open water of city parks, game farm wintering pens, private as well as public refuges, great and small, all on occasion have proved attractive enough to draw and hold stragglers from the outside, many of which have been distinctly tame from the time that they have come in."

It is considered to be doubtful that these birds would be able to live sedentary lives in North Central States marshes without winter feeding by man.

**An economic study of the food of the ring-necked pheasant in South Dakota**, H. C. SEVERIN ([*Brookings*]: *S. Dak. State Col., 1933, pp. 252, figs. 24*).—This report of a laboratory study of the food habits of the ring-necked pheasant (*Phasianus colchicus torquatus* Gmel.  $\times$  *P. colchicus colchicus* L.), first introduced into South Dakota in 1912, is based upon observations and a detailed analysis of the crop and gizzard contents of each of 285 individuals obtained from all representative areas where the pheasant was able to maintain itself in goodly numbers since April 1929.

"Plants whose seeds were found in the food tubes of our pheasants totaled 116 species. The bulk of the seeds eaten were included in the Gramineae, while seeds of Compositae, Polygonaceae, Rosaceae, Leguminosae, Solanaceae,

Violaceae, and Caprifoliaceae made up most of the remainder. A total of 140,219 seeds were found, which averages approximately 492 seeds per bird. Economically considered, approximately 25.7 percent of these seeds were useful to man, 34.8 percent were neutral in character, and 39 percent were harmful. "While pheasants eat a large number of noxious weed seeds, they do not reduce the numbers of such seeds per acre sufficiently to make any practical difference to the farmer or gardener."

The animal food eaten consisted principally of insects, but a comparatively small number of spiders, millepedes, and snails, and a small amount of broken up pheasant eggshells were also taken. A total of 3,471 complete or nearly complete animals were found in the crops and gizzards, but of this number 3,375 were insects. Forty percent of the animals were flies and their larvae. Next in order were the Orthoptera with 20 percent, Coleoptera 16, Hymenoptera 11, Lepidoptera 9, Hemiptera and Homoptera 2, and the Neuroptera with 0.3 percent. Spiders constituted 2 percent of the total number of animals eaten, while the Diplopoda (millepedes) and the snails accounted for 0.5 and 0.4 percent, respectively. Forty percent of the entire lot of animals eaten were classed as harmful to man, 3 percent were useful, 27 percent neutral, and 30 percent doubtful.

**Studies on the bank swallow *Riparia riparia riparia* (Linnaeus) in the Oneida Lake region.** D. STONEB (*Roosevelt Wild Life Ann. [Syracuse Univ.], 4 (1936), No. 2, pp. 122-233, pl. 1, figs. 49*).—Studies of the life history and habits of the bank swallow reported include an account of its parasites and foot diseases and a four-page list of references to the literature.

**The parasites of the muskrat (*Ondatra zibethica* L.) in the British Isles.** T. WARWICK (*Parasitology*, 28 (1936), No. 3, pp. 395-402).—A list is given of the helminth and ectoparasites of the muskrat, with their continental distribution, and a table showing the incidence and distribution of the three most commonly occurring species of muskrat ectoparasites in Great Britain, namely, *Laclaps multispinosus* Burm., *Listrophorus validus* Banks, and *Dermacarus* n. sp. Of the five species of helminths of the British muskrat, two (*Notocotylus quinqueserialis* Barker & Laughlin and *Hymenolepis evaginata* Barker & Andrews) have been introduced with the animal. The three other species of helminths (*Capillaria hepatica* (Bancroft), *Taenia taeniaeformis* (Batsch) larva, and *T. tenuicollis* Rud. larva) have probably been largely reacquired from the local fauna. All of the three common species of ectoparasites (*L. multispinosus* (*Tetragnonyssus spiniger*), *L. validus*, and *Dermacarus* n. sp.) occur in North America. Three other species (*Tyroglyphus* sp., *Myobia* n. sp., and *Polyplax* sp.) have occurred as single individuals, the last species having probably been acquired from the water vole (*Arvicola amphibius amphibius* L.). Introduction into Britain has greatly depleted the original helminth fauna as regards number of species and individuals, but not so with the ectoparasites. Lists of the parasites hitherto recorded from the muskrat are given and those of the brown rat (*Rattus norvegicus* Erx.) and water vole

**Plague infection discovered in fleas and lice taken from marmots in Montana and in a marmot in Utah** (*Pub. Health Rpts. [U. S.], 51 (1936), No. 34, pp. 1159, 1160*).—Record is made of the discovery by C. R. Eskey of plague infection in fleas and lice taken from ground hogs (marmots) killed in Small Horn Canyon, Mont., in July 1936. This finding is said to have provided the first direct evidence that plague exists among marmots in America and to demonstrate that the infection may be recovered from lice as well as fleas taken from these rodents. Fatal epizootics are said to have been noted among marmots in a number of localities in Western States, and reference is also made

to the discovery of plague in a sick ground hog killed in July 1936 in Indian Creek Canyon, Beaver County, Utah.

**Studies on *Strongyloides*.**—I, *S. ratti* in parasitic series, each generation in the rat established with a single homogonic larva, G. L. GRAHAM (*Amer. Jour. Hyg.*, 24 (1936), No. 1, pp. 71–87, figs. 2).—Experimental rats were infected with a single homogonic larva of *S. ratti* each. "The infections were demonstrated by the appearance of larval progeny in fecal cultures collected from 5 to 11 days later. Of 181 rats exposed to a single larva each, 58, or 32 percent, became positive culturally. The pure-line strain of the parasite was passed serially through 14 parasitic generations by means of these single larva transfers without recourse to the heterogonic mode of larval development. Analysis of the data from the single larva infections indicates that a male parasite is unnecessary in the bionomics of *S. ratti* either to maintain parasitic fertility or to explain the two modes of larval development. Hyperinfection as a source of either hypothetical male parasites or additional parasitic females finds no support either factually or inferentially in the data. The parasitic phase of *S. ratti* is thus represented by a female organism, which is either syngonic or parthenogenetic."

**A list of external parasites from birds of the eastern part of the United States**, H. S. PETERS (*Bird-Banding*, 7 (1936), No. 1, pp. 9–27).—The author's studies have led to the recording of 198 different species of external parasites, including the Mallophaga or biting lice, the Hippoboscidae or bird flies, the mites, and the ticks taken from 255 species and subspecies of wild birds in various States east of the Mississippi River during the years 1928 to 1935, inclusive.

***Plasmodium oti* n. sp., a plasmodium from the eastern screech owl (*Otus asio naevius*)**, infective to canaries, F. WOLFSON (*Amer. Jour. Hyg.*, 24 (1936), No. 1, pp. 94–101, pl. 1, figs. 2).—*P. oti*, isolated from the eastern screech owl and established in canaries, is described as new.

**Ecological investigations of the liver fluke snail *Limnea truncatula* in Jaeren** [trans. title], F. ØKLAND (*Meld. Norges Landbr. Høiskole*, 16 (1936), No. 6, pp. 449–470; *Ger. abss.*, pp. 467–469).—A report of studies of *L. truncatula* in southwestern Norway, contributed with a list of 23 references to the literature.

**A technic for clearing large insects**, P. STAPP and R. W. CUMLEY (*Stain Technol.*, 11 (1936), No. 3, pp. 105, 106, figs. 2).—A method that has been found to clear large insects successfully, highly pigmented animals and specimens with chitinous coverings being rendered translucent, is here described.

**Photomicrography of opaque objects**, J. G. PRATT (*Amer. Photog.*, 30 (1936), No. 6, pp. 348–352, 354, figs. 7).—A contribution on the technic of insect photography, particularly as relates to the depth of focus.

**Effect of low temperature in shortening the hibernation period of insects in the egg stage**, F. FLEMION and A. HARTZELL (*Contrib. Boyce Thompson Inst.*, 8 (1936), No. 2, pp. 167–173).—Egg masses of the eastern tent caterpillar collected in the fall were hatched at room temperature when given a pretreatment of from 8 to 12 weeks at 1°, 5°, and 10° C. The time required for hatching decreased as the period at low temperature increased. No hatching of larvae was obtained from those kept constantly at room temperature.

Eggs of the fall cankerworm also responded to low temperature exposures; while a few hatch when kept constantly at room temperature (about 22°), a much higher percentage is obtained at room temperature when preceded by periods of from 3 to 18 weeks at 1°, 5°, 10°, and 15°.

No low temperature treatment is required for the hatching of nymphs of the Chinese mantis. However, egg masses subjected for from 3 to 12 weeks at 5° were not injured.

**Report of the Chief of the Bureau of Entomology and Plant Quarantine, 1936, L. A. STRONG (U. S. Dept. Agr., Bur. Ent. and Plant Quar. Rpt., 1936, pp. 3-23, 27-37, 46-53, 57-91).**—The work of the year (E. S. R., 74, p. 814) with fruit and nut insects included codling moth control by the use of insecticides, bands, sanitation, baits, and parasites; control of the pear thrips on pears and prunes; oriental fruit moth; peach borer; plum curculio; San Jose scale; grape berry moth; grape leafhoppers (the grape leafhopper and related forms); the grape rootworm; pecan nut casebearer; pecan casebearer; black pecan aphid; hickory shuckworm; pecan phylloxera *Phylloxera devastatrix* Perg.; raisin moth *Ephestia figulilella* Greg.; citrus rust mite; orange thrips; California red scale; rhinoceros beetle *Strategus quadrifoveatus* Beauv.; coffee insects; the pineapple mealybug; Japanese beetle; and fruitflies (the Mexican fruitfly, *Anastrepha serpentina* Wied., melonfly, Mediterranean fruitfly, and West Indian fruitfly); and the citrus blackfly.

Insects affecting forest and shade trees referred to include the Black Hills beetle, mountain pine beetle, western pine beetle, forest tent caterpillar, European elm bark beetle *Scolytus multistriatus* Marsh. and the native elm bark beetle *Hylurgopinus rufipes* Eichh. (both vectors of the Dutch elm disease), the gypsy moth and brown-tail moth, and the satin moth.

Cereal and forage insect investigations referred to include the European corn borer; corn eurworm; 12-spotted cucumber beetle (a carrier of Stewart's disease), southwestern corn borer; fall armyworm; hessian fly; chinch bug; corn leafhopper *Peregrinus maidis* Ashm.; oroidal fly *Euxesta stigmatias* Loew; sugarcane borer; rice stinkbug *Oebalus pugnax* F.; corn leaf aphid, rusty plum aphid, a sedge aphid (*Carolinaia cyperei* Ainsl.), and *Aphis nerii* Kalt., which act as vectors of sugarcane mosaic; alfalfa aphid; alfalfa weevil; vetch aphid *Bruchus brachialis* Fahr.; lygacid plant bugs and pentatomid bugs on alfalfa seed; range caterpillars; grasshoppers; the Mormon cricket; and stored-grain insects.

Truck crop, garden, greenhouse, tobacco, and bulb insects reported upon include wireworms, the Mexican bean beetle, pea aphid, lima bean pod borer and other pod borers, tomato pinworm, corn earworm, sweetpotato weevil, vegetable weevil, mole crickets (especially *Scapteriscus acletus* R. & H.), the turnip aphid, lettuce loopers (*Autographa* spp.), the European earwig, onion thrips, imported cabbageworm, cabbage looper, diamondback moth, strawberry weevil, strawberry root aphid, raspberry fruitworm, red berry mite *Eriophyes cassinii* Hass., beet leafhopper, tobacco flea beetle, tobacco hornworm, tobacco budworm, tobacco thrips, tobacco webworm, cigarette beetle, tobacco moth, gladiolus thrips, red spider mites and thrips, the bulb mite, and mushroom pests.

Cotton insects mentioned include the bollweevil (including possible injury to soils by calcium arsenate), cotton flea hopper, bollworm, pink bollworm, several hemipterous insects, the cotton root aphid, and the Thurberia weevil.

Data on bees include diseases, beeswax, pollination, and bee breeding.

Insects affecting man and animals mentioned are screwworms and other blowflies, hornflies, mosquitoes, sand flies, eye gnats, ticks, surgical maggots, and household and stored-product insects.

In work on insect identification and foreign parasite introduction particular attention was given to the importation of natural enemies of the oriental fruit moth, Japanese and Asiatic beetles, elm leaf beetle, and fruitflies.

Insecticide and related studies under way include control of insects by fumigation, sterilization of plant products by high and low temperatures, method of applying insecticides, physiology of insects, toxic effect of insecticides on

insects, toxicity of insecticidal combinations of tobacco and tobacco products on insects, tests to determine the effect of new insecticidal materials on insects, and chemical investigations on (1) insecticidal plants (tobacco, derris, pyrethrum, etc.) and their constituents, (2) development of synthetic organic insecticides, (3) the removal of spray residue, (4) development of inorganic insecticides, (5) fumigants for control of insect pests, (6) oils and oil emulsions, (7) accessory materials for use with insecticides, and (8) determination of the toxicity of new insecticidal compounds, using goldfish.

[Contributions on economic insects, insecticides, and insect control] (*U. S. Dept. Agr., Bur. Ent. and Plant Quar., 1936, E-392, sect. 1, pp. [3]+198, sect. 2, pp. [3]+199-358, sect. 3, pp. [3]+359-628; E-393, pp. 8; E-394, pp. 4; E-395, pp. 4; E-396, pp. 8, pls. 8; E-397, pp. 5, pls. 11*).—Further contributions in this series (*E. S. R., 76, p. 501*) are A Bibliography of Nicotine—II, The Insecticidal Uses of Nicotine and Tobacco, by N. E. McIndoo, R. C. Roark, and R. L. Busbey (*E-392, 3 sections*); The Vetch Bruchid *Bruchus brachialis* Fahraeus, by P. N. Annand and J. S. Pinckney (*E-393*); Sulphur Dips for the Control of Goat Lice, by O. G. Babcock (*E-394*); Carpet Beetles (*E-395*); The Machinery-Piping System of Flour-Mill Fumigation, by G. B. Wagner, R. T. Cotton, and H. D. Young (*E-396*); and The Distribution of California Buckeye in the South-Central Sierra Nevada Counties in Relation to Honey Production, by G. H. Vansell and W. G. Watkins (*E-397*).

[Report of work in entomology by the Arkansas Station] (*Arkansas Sta. Bul. 337 (1936), pp. 42-46*).—The work of the year reported upon (*E. S. R., 74, p. 816*) relates to the sugarcane beetle and the strawberry crown borer, both by W. J. Baerg; the striped cucumber beetle, by D. Isely; variations in codling moth injury in northwestern Arkansas, by Isely and H. H. Schwardt (*E. S. R., 75, p. 669*); and the biology of horseflies, by Schwardt (*E. S. R., 76, p. 221*).

[Report of work in economic entomology], D. B. MACKIE and A. C. FLEURY (*Calif. Dept. Agr. Bul., 24 (1935), No. 4, pp. 403-430, 505, 506, 507, 508, 509, 511-527*).—The occurrence of and control work with the more important insects and related pests in California in 1935 are reported upon (*E. S. R., 74, p. 366*).

[Report of work in entomology by the Delaware Station] (*Delaware Sta. Bul. 203 (1936), pp. 22-35*).—The more important insects of the year (*E. S. R., 74, p. 66*) and a study to determine the factors responsible for the development of one and two annual broods of the plum curculio are reported upon by L. A. Stearns; bionomics and control of the codling moth, by Stearns, D. MacCreary, W. R. Haden, and P. L. Rice; and mosquito investigations, by Stearns and MacCreary.

[Report of work in entomology by the Michigan Station] (*Michigan Sta. [Bien.] Rpt. 1935-36, pp. 30, 31, 41*).—Brief reference is made to the work of the biennium (*E. S. R., 73, p. 505*), including zinc arsenate in codling moth control, oriental fruit moth parasites, control of other fruit tree pests, insects on ornamental plantings, termites, and dormant season sprays for aphids.

[Report of work in entomology by the Missouri Station] (*Missouri Sta. Bul. 370 (1936), pp. 51-55, 69, 70*).—The work of the year reported upon (*E. S. R., 75, p. 77*) includes biological studies on the codling moth, timing sprays by moth emergence, substitutes for arsenate of lead, mothproofing packing sheds, orchard control of codling moth and spray residue, effects of *Aenoplæa carpocapsæ* and weather on the codling moth, and bait trap experiments with codling moth, all by L. Haseman, L. Jenkins, and H. Koch; chinch bug control, hessian fly-resistant wheat varieties, and insect pests of melon and related crops, all by Haseman; the toxic action of various chemicals on codling moth larvae, by Haseman and

Koch; spraying tests with zinc arsenate, by H. G. Swartwout; and substitutes for arsenate of lead, by C. G. Vinson.

[Report of work in entomology by the New York State Station] (*New York State Sta. Rpt. 1936, pp. 39, 40, 48-62*).—The work of the year referred to (E. S. R., 74, p. 815) includes studies of calcium arsenate (E. S. R., 76, p. 215); spreading and wetting properties of insecticides and fungicides; spray residues; the codling moth and the tree hopper *Glossonotus crataegi* Fitch on apple; the codling moth on pears; the European red mite on plums; phototropic responses of the codling moth; insecticides used as dormant and early spring treatments; fruit insect investigations in eastern New York, particularly of the apple maggot, apple curculio, fruit tree leaf roller, scurfy scale, and white apple leaf-hopper on apple and several enemies of pears and small fruits; biological control of the oriental fruit moth by *Macrocentrus ancylovorus* and of the codling moth by *Ascogaster carpocapsae*; control of the oriental fruit moth on quinces; peach borers; nursery and ornamental insect pests, including the strawberry root weevil, black vine weevil, peach borer, oystershell scale, several spruce needle miners (particularly *Olethreutes abietana* Fern. and *Recurvaria picarella* Kieff.), the juniper webworm *Phalonia rutilana* Hübn., a scale insect (apparently *Lecanium fletcheri* Ckll.) and its attack on *Taxus*, *Juniperus*, and *Thuja*, and the pine needle scale; insect pests of canning crops, particularly the pea aphid, root maggots, and cherry maggots; and vegetable insect investigations on Long Island, particularly with the cabbage looper, Mexican bean beetle, corn earworm, and the fall armyworm.

[Contributions on economic insects in Oregon] (*Oreg. State Hort. Soc. Ann. Rpt., 27 (1935), pp. 58-65, 123-130, 163-165*).—Contributions presented at 1935 meetings of the Oregon State Horticultural Society and the Western Nut Growers Association include the following from the Oregon Experiment Station: Strawberry Pests, including Spittle Bug [*Aphrophora permutata* Uhl. and *Philacnus spumarius* Fall.], by W. D. Edwards (pp. 58-65), Common Errors in the Selection and Use of Sprays and Dusts, by R. H. Robinson (pp. 123-127), Control of the Pear or Prune Thrips [Pear Thrips] in Oregon, by S. C. Jones (pp. 127-130), and Wormy Filberts [*Balaninus* sp., probably *uniformis*, and *Melissus latiferreanus*], by B. G. Thompson (pp. 163-165).

[Contributions on economic insects and acarids] (*Ent. Soc. Brit. Columbia, Proc., No. 32 (1936), pp. 6-31*).—Contributions presented at the thirty-fourth meeting of the society (E. S. R., 73, p. 642), held in February 1935, include the following: The Production of Artificial Conditions Conducive to Winter Feeding of Ticks (*Dermacentor andersoni* Stiles), by J. D. Gregson (pp. 6, 7); Notes on the Moulting of Mites and Insects, by A. D. Heriot (pp. 8-10); A Check List of the Fleas of British Columbia, With a Note on Fleas in Relation to Sawdust in Homes, by G. J. Spencer (pp. 11-17); The European House Cricket (*Gryllus domesticus*) Now in Vancouver, by J. K. Jacob (pp. 18, 19); Entomological Illustrating, by G. R. Hopping (pp. 20-22); The Distribution of the Rhododendron White Fly [*Dialcurodes chittendeni* Laing] in British Columbia: Notes on Its Life History and Control Measures, by H. F. Olds (pp. 23-25); An Outbreak of *Autographa californica* Speyer Around Kamloops, Summer 1934, by G. J. Spencer (pp. 26-28); and Some Food Plants of Lepidopterous Larvae—List 3, by J. R. J. Llewellyn-Jones (pp. 29-31).

Pests of cultivated plants, M. H. RUHMANN (*Brit. Columbia Dept. Agr., Hort. Circ. 72 (1936), pp. 68, figs. 29*).—This general account of insect pests includes a discussion of sprays and spraying by B. Hoy (pp. 53-60).

[Economic insects in Kenya] (*Kenya Dept. Agr. Ann. Rpt., 1934, vol. 2, pp. 17-23*).—Brief reference is made to the occurrence of and work of the year with economic insects in Kenya.

**Annual report of the division of entomology for the year ended 31st December 1935**, R. W. JACK (*Rhodesia Agr. Jour.*, 33 (1936), No. 5, pp. 329-356).—The occurrence of and work of the year with economic insects, including those attacking man and animals, are reported upon (E. S. R., 74, p. 228).

**Report of the entomologist for 1935**, C. B. REDMAN KING (*Tea Res. Inst. Ceylon Bul.* 13 [1936], pp. 35-40, fig. 1).—The occurrence of and progress of work with insect enemies of tea in Ceylon in 1935 are reported.

**A preliminary report on an entomological survey of Guam**, O. H. SWEZEY (*Hawaii. Planters' Rec. [Hawaii. Sugar Planters' Sta.]*, 40 (1936), No. 4, pp. 307-314).—An annotated list is given of the crop pests known at the present time in Guam, based upon a survey conducted commencing on April 27, 1936.

**Insect damage to Empire products**, J. W. MUNRO (*Jour. Roy. Soc. Arts*, 84 (1936), No. 4365, pp. 925-933).—A general summary of information presented as an address.

**Insects in relation to production of red clover seed**, J. H. BIGGER (*Ill. State Acad. Sci. Trans.*, 28 (1935), No. 2, pp. 60-63).—The author considers the effect of insects on (1) the stand, (2) number of blooms, (3) condition of bloom, and (4) direct effect on seed.

**Experiments with derris for control of insect pests in the Netherlands Indies**, J. VAN DER VECHT (*Landbouw [Buitenzorg]*, 11 (1936), No. 10, pp. 401-465, figs. 5; *Eng. abs.*, pp. 461-464).—Preliminary tests of derris made with various insects under field conditions in the Dutch East Indies are reported upon.

**The relation between the degree of fineness of pyrethrum powder produced by different periods of grinding to toxicity to insects and to deterioration by light and air**, C. L. SMITH (*Jour. N. Y. Ent. Soc.*, 44 (1936), No. 4, pp. 317-339, pls. 3).—Following a review presented with a list of 15 references to the literature the author reports upon experiments conducted, the details of which are given in tables. The results obtained have led to the conclusion that the finer the pyrethrum powder is ground the more rapid is the rate of paralysis of mosquito larvae and the speed of kill of the bean aphid. The tests on aphids were conducted both as sprays and dusts with duplication of results. The surface area of the ground particles exposed to the extracting medium appears in each case to be the determining factor. In paralytic and mortality tests conducted the finer the pyrethrum was ground the more rapid was the deterioration of the toxic principles upon exposure to light. Data were obtained which have shown that the deterioration of pyrethrum by light can be prevented for a limited time by either tannic acid, an antioxidant, or titanium dioxide, a pigment which absorbs the injurious wave lengths of light. The degree of protection secured does not vary with the different finenesses of pyrethrum powder. Even when the protectants are present, the pyrethrum powder begins to lose toxicity after a certain length of exposure. The material containing titanium dioxide holds its toxicity slightly longer than that containing tannic acid.

**The practical use of insects for the control of insect pests and noxious weeds** (*Kans. State Bd. Agr.*, [Quart.] Rpt., 55 (1936), No. 217-A, pp. 29-41).—Two contributions are presented as follows: The Use of Insects for the Control of Insect Pests, by G. A. Dean (pp. 29-33), contributed from the Kansas Experiment Station, and The Use of Insects for the Control of Noxious Weeds, by S. G. Kelly (pp. 34-38).

**Parasites introduced into Barbados for control of insect pests**, R. W. E. TUCKER (*Agr. Jour. [Barbados]*, 5 (1936), No. 1, pp. 1-22).—This contribution reports upon 14 insect parasites that have been introduced into Barbados since 1927 in an attempt to secure biological control of various insect pests.

No positive results have been obtained from the majority of these introductions. Some projects, such as the establishment of *Lixophaga diatraeae* Towns. and *Pyrophorus luminosus* Ill. are still in progress, and one parasite, namely, *Paratheresia claripalpis* V. d. Wp., is to be reintroduced.

The status of *Bufo marinus*, the giant toad introduced over 100 yr. ago into Barbados, is discussed. The reasons for its diminution to the point of ineffectiveness are noted and suggestions made for its artificial propagation as a control over the pests *Lachnosterna smithi* and *Diaprepes abbreviatus*.

**A biological study on some common Philippine termites**, G. A. PANGGA (*Philippine Agr.*, 25 (1936), No. 3, pp. 233-265, figs. 16).—The termites the biology of which is here noted include *Macrotermes gilvus* (Hagen), *Microcerotermes los-bañosensis* Oshima, *Coptotermes vastator* Light, *Nasutitermes luzonicus* Oshima, *Cryptotermes noccens* Light, *C. cynocephalus* Light, and *Hospitalitermes hospitalis* (Haviland).

**The termite *Microtermes pallidus* Hav. in relation to tea in Malaya**, G. H. CORBETT and N. C. E. MILLER (*Straits Settlements and Fed. Malay States Dept. Agr., Sci. Ser. No. 17* (1936), pp. [2]+12, pls. 4).—This contribution includes the results of experiments aimed at the prevention of attack of tea by *M. pallidus*.

**Mormon cricket control in Nevada, 1935**, G. G. SCHWEIS and L. M. BURGE (*Nev. State Dept. Agr. Bul. 1* (1936), pp. 15, figs. 9).—Details of control work with the Mormon cricket in which two methods of control were employed, namely, poisoning by the use of arsenical dust and trapping the migrating crickets, are reported.

**Studies on *Schistocerca gregaria* Forsk., I-VII** (*Indian Jour. Agr. Sci.*, 3 (1933), No. 4, pp. 639-645, pl. 1; 6 (1936), No. 2, pp. 188-262, figs. 6; 263-267; 3, pp. 586-590; 591-623, pls. 3; 624-664, pls. 5; 665-671, figs. 4). Seven contributions on studies of the desert locust (*S. gregaria*) are presented by M. A. Husain and the following junior authors: The Micropyle in *Schistocerca gregaria* Forst. and Some Other Acridiidae, M. L. Roonwal (pp. 639-645); The Biology of the Desert Locust, With Special Relation to Temperature, T. Ahmad (pp. 188-262); Why Do Locusts Eat Wool? A Study in the Hydromania of *Schistocerca gregaria*, C. B. Mathur (pp. 263-267); Colour Changes and Sexual Behaviour in Desexualised *Schistocerca gregaria* Adults, K. Das Baweja (pp. 586-590); Pigmentation and Physical Exertion, C. B. Mathur (pp. 591-623); Influence of Temperature on the Intensity and Extent of Black Pattern in the Desert Locust Hoppers Bred Crowded, T. Ahmad (pp. 624-664); and Factors Determining the Movement of the Vermiform Larvae, Des Raj Bhatia (pp. 665-671).

**The spotted locust *Aularches miliaris***, J. C. HURSON (*Trop. Agr. [Ceylon]*, 85 (1935), No. 2, pp. 127-129, pl. 1). This grasshopper (*A. miliaris*) is said to have been known as a periodical pest of estate and village crops in Ceylon for about 40 yr., mainly in the middle portion of the Central Province.

**The bedbug and its control** [trans. title], H. KEMPER (*Kleintier u. Pelztier*, 12 (1936), No. 3, pp. 107, figs. 18).—A monographic account of this pest, presented with a 12-page list of references to the literature.

**Control of the bean leafhopper**, S. W. CLARK (*Tex. Farming and Citricult.*, 13 (1936), No. 3, p. 13).—Contributing from the Texas Experiment Station, the author describes an efficient and relatively inexpensive control measure employed against the potato leafhopper on beans which consists of a mixture of finely ground sulfur dust and ground pyrethrum flowers. "For dusting beans, a ground sulfur should be specified, 99 percent of which will pass a 325-mesh sieve. Pyrethrum flowers should be added to the sulfur dust in sufficient quantity to bring the pyrethrin content to 0.05 percent. If quicker elimination of the hopper is desired, the pyrethrin content may be increased to 0.10 percent. This latter dosage is usually recommended.

"If pure pyrethrum dust is used, mix 1 part with 9 parts of finely ground, conditioned sulfur to make a dust containing 0.1 percent pyrethrins, but if an activated pyrethrum dust is used containing only 0.5 percent pyrethrins, mix 2 parts of the activated dust with 8 parts of finely ground, conditioned sulfur.

"The sulfur-pyrethrum mixture is usually applied at the rate of from 25 to 30 lb. per acre, depending on the size of the plants." Two treatments have been found to be sufficient in most cases, but three may be needed to control severe infestations.

**Apple leaf-hoppers: An outbreak in Victorian orchards, K. M. WARD** (*Jour. Dept. Agr. Victoria*, 3½ (1936), No. 7, pp. 328-330, 376, figs. 5).—This contribution relates to *Typhlocyba australis* Frogg, a severe outbreak of which occurred in the northeastern section of Victoria during the season of 1935-36. It is said to be the first outbreak of its kind in apple orchards in that State.

**Additions to the New York State list of aphids, with notes on other New York species, M. D. LEONARD** (*Jour. N. Y. Ent. Soc.*, 44 (1936), No. 3, pp. 177-185).—Forty-two species and 1 variety are added to the 128 species of Aphididae included in the list issued by the New York [Cornell] Experiment Station in 1928 (E. S. R., 58, p. 754), together with information on their occurrence and host plants.

**Capitophorus aphids infesting Artemisia, G. F. KNOWLTON and C. F. SMITH** (*Canad. Ent.*, 68 (1936), No. 10, pp. 229-234, figs. 35).—In this contribution from the Utah Experiment Station on aphids infesting *Artemisia*, or sage, of which plant there are approximately 75 species that occur in the Rocky Mountain region (several being of great economic importance as food for range livestock), 8 species of the genus *Capitophorus* are noted, of which 6 are described as new.

**The relation of aphids to the transmission of bean mosaic, W. J. ZAUMERMEYER and C. W. KEARNS** (*Phytopathology*, 26 (1936), No. 7, pp. 614-629).—In virus transmission experiments with bean mosaic virus, 11 aphid forms collected from 17 different host plants were found to transmit the virus, namely, the melon aphid, cowpea aphid, bean aphid, *Aphis spiraeicola*, the cabbage aphid, *Hyalopterus atriplicis* L., *Macrosiphum ambrosiae* Thos., the potato aphid, pea aphid, and the green peach aphid. A single species tested, *Neothomasia populicola* Thos., collected from the cottonwood tree, gave negative results. Fourteen species of aphids were found on beans in the field, and it is considered likely that a careful search would reveal more. Transmission studies with 10 species of insects other than aphids commonly found feeding on beans yielded negative results.

**Atmospheric HCN fumigation for Latania scale on avocado fruits, D. L. LINDGREN and H. L. MCKENZIE** (*Calif. Dept. Agr. Bul.*, 25 (1936), No. 3, pp. 369-377, fig. 1).—The results of fumigation control work with the *Latania* scale *Aspidiotus lataniae* Sign. (E. S. R., 75, p. 380), conducted by the California Citrus Experiment Station, are reported upon. It is concluded that on avocado fruit this scale can be killed by atmospheric fumigation, a dosage of 25 cc of liquid hydrocyanic acid, or its equivalent, per 100 cu. ft. being recommended. With a load of 50 avocado boxes per 100 cu. ft., exposure should be for 1 hr., with electric fan circulation.

**A study of the gypsy moth in the town of Petersham, Mass., in 1935, W. L. BAKER and A. C. CLINE** (*Jour. Forestry*, 34 (1936), No. 8, pp. 759-765, figs. 2).—This is a report of a study aimed at the determination (1) of the reactions of the gypsy moth to its food supply in an area never before heavily defoliated, in order to learn whether it had increased to outbreak numbers irrespective of food plants or only in concentrations of favored food, and (2) of the extent any discriminating food habits of the insect that might be dis-

covered would permit the application of silvicultural measures of control in a particular locality.

**A common tussock-moth, *Porthesia* (Euproctis) *scintillans* Wlk., in Canton** (Lepidoptera: Lymantriidae), Y. C. NG (*Lingnan Sci. Jour.*, 15 (1936), No. 3, pp. 483-486, figs. 5; *Chin. abs.*, p. 486).—The tussock moth *P. scintillans*, found in Canton and vicinity most of the year though not an extremely serious enemy of any one crop, is a quite important pest through being a general feeder.

***Alucita niveodactyla* Pag. (Microlepidoptera: Pterophoridae), a pest of sweet potatoes in Kwangtung**, W. E. HOFFMANN (*Lingnan Sci. Jour.*, 15 (1936), No. 2, pp. 311, 312, figs. 3; *Chin. abs.*, p. 312).—Notes are presented on a lepidopteran of the family Pterophoridae (*A. niveodactyla*), the caterpillar of which causes extensive damage, particularly during December, to leaves of the sweet-potato in the Canton area.

**Injury to pines by *Tortrix* (Amelia) *pallorana* Rob., E. I. McDANIEL** (*Michigan Sta. Quart. Bul.*, 19 (1936), No. 2, pp. 92-94, figs. 2).—Observations made during an outbreak of *T. pallorana* among young pine transplants in the vicinities of East Lansing and Augusta, Mich., in 1936, in which the new growth on about 95 percent of the white pine was killed before discovery of the infestation, are reported upon. About 200 acres of from 4- to 6-yr. old white, red, Scotch, and jack pine transplants were involved. The plantings were mixed stands and all species were infested, but the larvae showed a decided preference for white pine.

The larvae encloses its food supply by drawing two or more tender shoots together and fastening them with a loose web. Where the shoots are close together all are excavated, for the larva does not confine its feeding to the tender needles but also tunnels into the tender new growth, such tunnels being extensive and new growth killed. The larvae were readily controlled by the application of either a contact or stomach poison, but since the infestation on pines occurs only when the new growth is developing rapidly, it is impossible to protect the trees with a single application. A spray consisting of 1 pt. of 40-percent nicotine sulfate to 100 gal. of water plus 4 lb. of dissolved soap is recommended.

**The biology of the orange tortrix (*Eulia* (*Argyrotaenia*) *citrana* Fern.)**, W. H. LANGE, JR., (*Calif. Dept. Agr. Bul.*, 25 (1936), No. 2, pp. 283-285, fig. 1).—The author records the finding of larvae of the orange tortrix webbing the needles and defoliating young potted Monterey pines at Berkeley, Calif., during the summers of 1933 and 1934. Later it seemed to be of little importance to young pines because of the few trees attacked. An account is given of its life history based on the successful rearing of 15 adults through the complete life cycle, supplemented with many partial records and observations on the trees under natural conditions.

**The needle-tying moth *Tortrix excessana* Walk., A. F. CLARK** (*New Zeal. Jour. Sci. and Technol.*, 17 (1936), No. 5, pp. 679-685, figs. 4).—The larva of the tortricid here considered is a source of much injury by webbing the needles together into a tube, the cuticle being consumed in whole or in part, causing them to turn brown and die. The attack reaches a climax after two or three seasons and then rapidly declines, in many cases ceasing completely.

**The fruit leaf roller (*Cacoecia argyrospila* (Wlk.)), a defoliator of the orange in California**, W. H. LANGE, JR. (*Calif. Dept. Agr. Bul.*, 25 (1936), No. 3, p. 387).—The webbing and rolling of the leaves of orange trees and feeding on the buds by the larvae of the fruit tree leaf roller are reported upon.

**Results of miscellaneous insecticides used on larvae of the peach twig borer in hibernation**, H. K. PLANK (*Calif. Dept. Agr. Bul.*, 25 (1936), No. 2,

pp. 216-225).—In experimental control work with the peach twig borer, 34 different treatments were applied from December 9, 1932, to March 1, 1933, to 1-year-old water sprouts growing on peach stumps in two abandoned orchards in the center of the northern California cling peach district.

"A white mineral oil of about 52 sec. viscosity and 95 percent unsulfonated residue gave about the best results of the unemulsified oils tried and caused a minimum of injury to the parasites and the tree. A lighter oil blend and its combinations with toxic compounds injured the trees more or less severely, killed many of the parasites, and indicated somewhat inferior control of the borer. The heavy oils, emulsified or otherwise treated to make them emulsive or miscible in water, indicated very poor control and injured the twigs at the strengths used. The pine tar oils and beta-naphthol, employed by other workers in the control of the codling moth in hibernation, gave uniformly poor control of the twig borer in a similar state, though none injured the plant or seemed to affect the parasites. Commercial liquid lime-sulfur at the strength generally used to combat the borer during the early blooming stage of the peach gave control decidedly inferior to a number of oil treatments. The addition of fumigants did not seem to increase the toxicity of the sprays containing them nor adversely affect the parasites or the plant. Pyrethrum added to one oil and an oil emulsion seemed to improve very markedly the control of the borer without killing the parasites or injuring the plant.

"More extensive trials should be carried on, particularly with 'white' oils between 50 and 60 sec. viscosity alone and in combination with pyrethrum and nicotine, in order definitely to establish the value of these materials in the control of the peach twig borer in hibernation. The injurious effects produced on peaches by very 'light' and very 'heavy' oils of low sulfonation indicate what might be expected should materials of these classes be used in commercial applications."

**Studies on the pine shoot moth (*Evetria buoliana* Schiff.)** ([*Gt. Brit. J. Forestry Com. Bul.* 16 (1936), pp. 46, pls. 7, figs. 2).—The biology and forest relations of the European pine shoot moth are dealt with by C. C. Brooks (pp. 6-26), and the status of the pest in East Anglia and experiments in control, by J. M. B. Brown (pp. 27-43). A bibliography of 52 titles is presented.

**Codling moth control work in the Department of Puy-de-Dôme** [trans. title], H. SOULIÉ (*Ann. Épiphyt. et Phytogénét.*, n. ser., 2 (1936), No. 2, pp. 159-189, figs. 7).—Data on the biology of the codling moth as influenced by temperature and humidity and the progress of control work are reported, with a list of 57 references to the literature.

**Codling moth control investigation**, W. W. YOCUM (*Nebr. State Bd. Agr. Ann. Rpt.*, 1935, pp. 552-554).—Codling moth control tests conducted in 1934 in an orchard at Shubert, Nebr., showed that nicotine sulfate used with oil gave the best control (29.9 percent wormy), followed by lead arsenate (27.4), Kalo (35.3), calcium arsenate (41.7), and Black Leaf 155 (45.9 percent). The results obtained with chemically treated bands were very irregular.

**Variations in the effectiveness of chemically treated codling moth bands**, G. A. FILINGER (*Amer. Soc. Hort. Sci. Proc.*, 32 (1935), pp. 191-194).—Work at the Kansas Experiment Station, the details of which are given in three tables, has led to the following conclusions: "Chemically treated codling moth bands are less effective in killing larvae during seasons of high temperatures than during normal seasons. Bands carrying a heavy load of  $\beta$ -naphthol are more effective than those with low  $\beta$ -naphthol content. Where heavy loads are used, tree trunks can be protected with asphalt emulsion, water glass, or linseed oil. Four-in. bands, unless very carefully dipped, are less effective than 2-in. bands. The addition of aluminum stearate to  $\beta$ -naphthol and oil makes the

chemicals sticky. Bands in which the chemicals retain a gummy, sticky consistency are more effective than those in which the  $\beta$ -naphthol becomes dry and crystalline."

**California microlepidoptera, VIII, H. H. KEIFER** (*Bul. South. Calif. Acad. Sci.*, 35 (1936), No. 1, pp. 9-29, pls. 4).—Of the five new species described in this further contribution (E. S. R., 74, p. 71), *Eucordylea huntella* bores into and destroys the flower buds of azalea, *Aristotelia eldorada* feeds on the young leaves and blossom buds of *Adenostoma fasciculatum*, and *Gelechia langeti* attacks *Pinus ponderosa*.

**California microlepidoptera, IX, X, H. H. KEIFER** (*Calif. Dept. Agr. Bul.*, 25 (1936), Nos. 2, pp. 235-259, pls. 7; 3, pp. 349-359, figs. 20).—Part 9 of this continuation of the study above noted reports upon (1) moths of the genus *Gnorimoschema* (including *Phthorimaea*), six in number, of which two are described as new; (2) three species of the genus *Gelechia*, of which one is described as new; (3) one species of the genus *Deoclonia*; and (4) one new species of the newly erected genus *Argyrocladia*. In addition to descriptions of the adults and of the immature stages of some of the species, notes are given on their occurrence and biology.

In part 10 the author reports having found that while adults reared from tomato and potato represent the true tomato pinworm a group of specimens almost entirely reared from native *Solanums* represents a darker species native to the State to which the name *Gnorimoschema chmoei* is given. "There seemed to be sufficient evidence that this darker species was native in the State, whereas the true pinworm had entered California from some point to the south." A description of the adults and notes on *Scotostoma fernaldella* Riley are also presented.

[Contributions on the control of the white rice borer *Scirpophaga innotata* Walk.] (*Landbouw [Buitenzorg]*, 11 (1936), No. 11, pp. 473-509, figs. 4; *Eng. abs.*, pp. 482, 501, 502, 508, 509).—The contributions presented are Biological Foundations of Riceborer-Control [*S. innotata*], by P. van der Goot (pp. 473-483); The Problem of the Rice Borer in Krawang, by J. H. L. Joosten (pp. 484-502); and Experiences Concerning Irrigation in Connection With Control of the White Rice-Borer in West-Brebes (Residency Pekalongan, Java), by J. C. T. Kroesen (pp. 503-509).

**A recent army worm outbreak, J. A. WEDDELL** (*Queensland Agr. Jour.*, 45 (1936), No. 5, pp. 449-460, figs. 6).—An outbreak of *Spodoptera exempta* Walk. which resulted in the destruction of forage crops and pasturage in the near Brisbane areas is reported upon.

**Oviposition by *Heliothis obsoleta* Fab. on the silks of corn, W. J. PHILLIPS and G. W. BARBER** (*Virginia Sta. Tech. Bul.* 58 (1936), pp. 14, figs. 5).—In this further report of their studies of the corn earworm (E. S. R., 71, p. 816), observations "of the silking periods of two varieties of field corn planted each year on 11 different planting dates in 4 yr. (1924 to 1927) at Charlottesville, Va., and in 3 yr. (1925 to 1927) at Richmond, Va.," are dealt with. "The number of earworm eggs received by the corn planted on the several dates selected is also discussed.

"From the results of field counts it was possible to construct curves showing the progress of silking in each of the 142 plats studied. . . . It was found that these silking curves were variable, both in respect to the duration of this period of growth and in respect to the percentage of plants observed in silk at any one time. These divergences were shown to be the result of varying weather conditions during the silking periods in the several years in which the studies were made. The curves for early and late plantings showed the greatest variation in the time covered by the silking, while those of the midseason plantings,

especially those of May 28, covered very nearly equal periods. The silking periods in plats of Boone County White corn average somewhat longer than those in plats of Reid Yellow Dent corn. The average duration of the periods when 10 percent or more of the plants had moist silks did not vary greatly in the plats of the several planting dates. The average duration of the periods when 50 percent or more of the plants had moist silks was somewhat greater in plats of midseason or late planting dates than in plats of earlier plantings. . . .

"The seasonal history of the insect varied greatly for the years covered by these studies, and consequently there was great variation in the number of eggs deposited per plant per day, not only for plats representing different planting dates but for plats of any one particular planting date. Notwithstanding this fact, it was clearly shown that the later the corn was planted the greater the number of earworm eggs it received during the silking period, with the exception of the year 1927, in which the seasonal history was most unusual. In general, early plantings of corn receive the least number of eggs during the silking period, midseason plantings receive a larger number, and late plantings receive the greatest number of eggs. Therefore, to lessen earworm injury, field corn should be planted on or before May 8 in the latitude of Virginia, or in localities where the seasonal history of the insect is similar, in order that the plants may receive the least number of eggs while fresh silks are exposed, and thus be less severely damaged by the earworms."

**Studies of the ecology and control of cutworms in Tennessee, W. W. STANLEY** (*Tennessee Sta. Bul. 159 (1936), pp. 16, figs. 6*).—Information obtained on the growth rate of the immature stages of seven species of noctuid moths, particularly the dingy cutworm and *Feltia ducens*, when bred at constant temperatures showed the higher temperatures to accelerate development of all stages except the prepupal stage of the dingy cutworm and *F. ducens*. The increase in length of the prepupal stage of these two species at the higher temperatures appears to be a natural reaction which allows them to exist over a wide range of temperature conditions. "The other species studied are multiple brooded, and they completed their growth in a relatively short time as compared with the dingy cutworms. The fall armyworm showed a more rapid rate of growth by completing its cycle in 24.4 days from egg to adult at 30° C. Moths of dingy cutworms confined at constant temperature showed that 28° was about the optimum for egg laying.

"A study of the climatic factors indicates that a dry fall (September, October, November) and a warm winter are the conditions that favor moth abundance for the dingy cutworm. A rather wet fall, with the remainder of the year dry, favored adult abundance of *F. subgothica*. Location of light traps affected the catch of moths. A trap on top of a 5-story building caught more moths than a similar trap operated on the ground or on an 18-story building. Moths have been caught from April 5 to December 23. More moths are caught during the last week of August and first week of September than at any other time. Near-normal rainfall is favorable for large moth catches. A variation from normal tends to decrease the moth catch.

"Data obtained from light traps operated in various environments, such as patches of tomatoes and corn, indicate that some species are attracted, others are repelled, and still others are not affected, by environment. Numerous tests with dingy cutworms showed that 0.5 lb. of sodium fluosilicate mixed with 25 lb. of wheat bran is more toxic to cutworms than paris green or other arsenicals used at the same strength."

**Aids to the identification of anopheline imagines in Malaya, B. A. R. GATER** (*Singapore: Govt., 1935, pp. 242, pls. 9, figs. 236*).—This handbook includes an index to the anopheline species and subspecies of mosquitoes of Malaya;

accounts of their external and internal anatomy; life history and habits; collection and rearing; preservation and mounting; and examination, maintenance, and dissection; notes on the use of keys; a table for rapid identification; a note on the illustrations of species; brief descriptions of species; etc.

**A review of the Nearctic species of *Chloropisca* (Diptera, Chloropidae),** C. W. SABROSKY (*Canad. Ent.*, 68 (1936), No. 8, pp. 170-177).—This synopsis of the Nearctic species of the chloropid genus *Chloropisca*, contributed from the Michigan Experiment Station, is presented with notes on their distribution as checked by the author and a key to the 11 known species. *C. glabra* Meig., whose larvae are predaceous upon root aphids and are especially important predators of the sugar beet aphid, is the only species of which the life history is well known.

**The fly problem in rural hygiene** (*League Nations Health Organ. Quart. Bul.*, 5 (1936), No. 2, pp. 211-236, figs. 4).—The following contributions are presented: Report of the Meeting of Entomologists Convened by the Health Organisation of the League of Nations on the Fly Problem in Rural Hygiene (held in London on December 16 and 17, 1935) (pp. 211-213); The Biothermic Method of Fly Destruction and the Ease With Which It Can Be Adapted to Rural Conditions, by E. Roubaud (pp. 214-218); Investigations Into the Fly Density in Hungary in the Years 1934 and 1935, by F. Lörincz and G. Makara (pp. 219-227); and On Flies Visiting Human Faeces in Hungary, by F. Lörincz, G. Szappanos, and G. Makara (pp. 228-236).

**Studies on the influence of the environment on the sheep blow-fly *Lucilia sericata* Meig.—IV, The indirect effect of temperature and humidity acting through certain competing species of blow-flies,** A. C. EVANS (*Parasitology*, 28 (1936), No. 3, pp. 431-439, figs. 2).—In a further study (E. S. R., 74, p. 73) of the comparative resistance to high temperature and various humidities of four species of blowflies (*Calliphora erythrocephala* Meig., *L. sericata*, *Sarcophaga falcata* Pand., and *Phormia groenlandica* Zett.), the last was found to be the most resistant and *C. erythrocephala* the least resistant species.

**Further experiments upon the longevity of *Xenopsylla cheopis* Roths. (Siphonaptera),** H. S. LEESON (*Parasitology*, 28 (1936), No. 3, pp. 403-409, figs. 3).—In further experiments (E. S. R., 68, p. 71) with the oriental rat flea, it was found that "fleas fed once before starvation lived longer than unfed fleas. There was no difference between survival of the sexes and no direct proportion between survival times and saturation deficiency. Fleas kept with the host for 7 days before starvation lived still longer. Females lived considerably longer than males, but there was still no direct proportion between survival times and saturation deficiency."

**Recent developments in the use of electric light traps to catch the Asiatic garden beetle,** H. C. HALLOCK (*Jour. N. Y. Ent. Soc.*, 44 (1936), No. 4, pp. 261-279, figs. 4).—The results of a study of trap lights to catch the Asiatic garden beetle, commenced in 1927 and continued each year through 1934, are reported upon. It is pointed out that because of its attraction to light this beetle has become a nightly nuisance near brightly lighted places of business and amusement on warm summer evenings. A funnel trap 4 ft. in diameter with a 500-w daylight bulb, in use from 1928 to 1931, caught as high as 188,250 beetles during a season. Laboratory studies have shown that lights of short wave length near the violet end of the spectrum are most attractive to the beetle. The results of the work with 5 types of lights and 6 types of traps used in the experiments are reported upon. Some factors, such as temperature, type of light, and construction of trap, that influence the efficiency and usefulness of traps are discussed.

**Life history and control of the Asiatic garden beetle**, H. C. HALLOCK, rev. by I. M. HAWLEY and H. C. HALLOCK (*U. S. Dept. Agr. Circ. 246, rev. (1936), pp. 20, figs. 13*).—This is a complete revision of the account prepared in 1932 (E. S. R., 68, p. 791), the present status of knowledge of the pest being summarized.

**The alimentary tract of the margined blister beetle (*Epicauta cinerea marginata* Fab.)** (Coleoptera, Meloidae), R. T. EVERLY (*Ohio Jour. Sci., 36 (1936), No. 4, pp. 204-216, figs. 11*).—A study of the morphology and histology of the alimentary tract of the margined blister beetle, collected in southeastern Ohio, is reported upon with a list of 28 references to the literature.

**The introduction of the Chinese ladybeetle into citrus groves**, J. R. WATSON (*Citrus Indus., 17 (1936), No. 5, pp. 15, 18, 19*).—The ladybeetle *Leis dimidiata 15-spilota*, introduced into northern Orange Co., Fla., citrus groves from California as previously noted (E. S. R., 56, p. 855), is said to have survived two very unfavorable winters and to be spreading in a very satisfactory manner from the original center. It has been found over an area of approximately 15 miles in radius, occurring as far north as Winter Garden and in Orlando (E. S. R., 75, p. 658).

**An anatomical and systematic study of the genus *Anatis* of America** (Coleoptera, Coccinellidae), H. L. MCKENZIE (*Calif. Univ. Pubs. Ent., 6 (1936), No. 10, pp. 263-272, figs. 11*).—A description is given of six species of ladybird beetles of the genus *Anatis*, little of the life history of which is known. A list is given of the insects known to be fed upon by members of the genus and a bibliography of 27 titles.

**Studies in the genus *Aulicus* Spinola** (Coleoptera, Cleridae), E. G. LINSLEY (*Calif. Univ. Pubs. Ent., 6 (1936), No. 9, pp. 249-262, figs. 17*).—Twelve species of the genus *Aulicus* are recognized, of which 3 are described as new. Life history observations of *A. terrestris* Linsley under laboratory and field conditions show a definite relationship between *A. terrestris* and the lubber grasshopper *Essiclenia vanduzeei* Heb., upon the eggs of which the larvae feed. Of the lepidopterous larvae, Noctuidae are most commonly used for food.

**Plowing as a means of destroying wireworm pupae in the Pacific Northwest**, F. H. SHIRCK (*U. S. Dept. Agr. Circ. 407 (1936), pp. 8*).—Studies made by the Bureau of Entomology and Plant Quarantine and the Idaho Experiment Station, cooperating to determine the effect of plowing on wireworm pupae in irrigated lands of southern Idaho, are reported upon.

It was found that *Limonius californicus* and *L. canus*, the principal species met with, pass about 21 days in the pupal stage, the different individuals entering that condition from about July 15 to August 15. "The larvae and adults are not easily killed, but the pupae are extremely fragile and easily killed by injury, high temperatures, or the drying of the soil. Plowing to combat wireworms by destroying the pupae should be carried on during the first week of August in southern Idaho. It has been found that on the average approximately 75 percent of the pupae of *Limonius* can be killed by plowing. This represents a practical aid to wireworm control that can be accomplished with no additional expense except that involved in plowing to an average depth not more than 3 in. greater than the plowing depth now in vogue. Apparently the best results are produced by plowing to a depth of 8 or 9 in. and leaving the soil surface rough. No significant number of immature larvae are killed by ordinary plowing methods. Mechanical injury is apparently responsible for the larger portion of the pupal mortality, supplemented by the effect of exposure to summer heat and low humidities. Fields that have been in small grain and fields devoted to the production of early truck crops, such as peas

and early potatoes, can be plowed during the optimum period for destroying wireworm pupae."

**Wireworm-infestation trends accompanying certain crop rotations in the Pacific Northwest**, F. H. SHIRCK and H. P. LANCHESTER (*U. S. Dept. Agr. Circ. 408* (1936), pp. 10).—In connection with the cooperative work above noted a study was made of crop rotations and cultural practices in their relationship to the reduction of wireworm numbers. Fluctuations in wireworm infestations were observed for four seasons under a variety of crop rotations.

Plats containing alfalfa and with low initial populations showed a gradual though significant increase in the number of wireworms during the 4-yr. period. It appears that abnormal conditions for wireworm survival may be developed through the growing of red clover or through the intensive drying out of the soil. "The former results in rapid increases in the number of wireworms. The drying of the soil was partially obtained through the growing of unirrigated wheat, in which case decreases exceeding 50 percent of the wireworms resulted in one season. In the instance of late truck crops where a dry mulch was maintained during much of the season of beetle flight, the infestation has remained about stationary. The only significant effect upon the infestations under pasture-sod conditions has been the reduction of the population in a plat which had a high initial infestation. Plats planted to sugar beets and general garden crops show an increase in number of wireworms fully as significant as that of alfalfa, although not so consistent. The variation in the crops included in this rotation may account for the irregularities."

**The Colcoptera injurious to cereals and cereal products**, P. WIRTH (*Les Coléoptères nuisibles aux céréales et aux produits dérivés. Paris: Libr. le François, 1934, pp. 125, figs. 34*).—This account is accompanied by a list of 122 references to the literature.

**Relative susceptibility of ponderosa pines to bark-beetle attack**, F. P. KEEN (*Jour. Forestry, 34* (1936) No. 10, pp. 919-927, fig. 1).—A description is given of the bark beetle (principally the western pine beetle) susceptibility of ponderosa pines, based upon studies conducted by the author in southern Oregon and northern California from 1927 to 1932 and a review of earlier work. The subject is dealt with under the headings of age groups (four in number), vigor groups (four in number), relative susceptibility of the tree classes, and application to marking practice.

**Rhigopsis effracta Lec. attacking grape buds in California**, H. L. MCKENZIE (*Calif. Dept. Agr. Bul., 25* (1936), No. 2, p. 272).—The curculionid weevil *R. effracta* has been found by the California Citrus Experiment Station infesting the buds of grapevines at Colton, Calif. There were usually three or four weevils on each bud, the buds of grape cuttings being eaten as rapidly as they could grow out, and many of the cuttings had ceased to grow. Fairly satisfactory control was obtained from the use of tanglefoot.

**Notes on a European weevil, Ceutorhynchus assimilis Payk., recently found in the State of Washington**, W. W. BAKER (*Canad. Ent., 68* (1936), No. 9, pp. 191-193).—The author records the collection of *C. assimilis*, known in Europe as the turnip seed, radish seed, and cabbage shoot weevil, from mustard at several localities in Whatcom County and at Big Lake, Skagit County, Wash. Notes gleaned from the literature are given on its host plants, life history, and control in Europe, where it appears to be of considerable economic importance.

**The nature of resistance in cotton plants to stem-weevil**, K. DHARMABAJULU (*Assoc. Econ. Biol., Coimbatore, Proc., 3* (1935), pp. 21-31, pls. 3).—The author finds that cotton plants resist an attack of the stem weevil *Pemphorus affinis*

**Est. by regeneration and repair of the tissues each time the plant is attacked and by the production of a wound gum which kills the grub.**

**Package bees and how to install them**, C. B. GOODERHAM (*Canada Dept. Agr. Pub.* 507 (1936), pp. 11, figs. 7).—This is a revision of Pamphlet 107 (E. S. R., 63, p. 359).

**Catalog of the Hymenoptera.—I, Tiphidae**, edited by H. HEDICKE (*Hymenopterorum Catalogus.—I, Tiphidae. 's Gravenhage (The Hague): W. Junk, 1936, pp. 32*).—This first part of the work takes up the family Tiphidae and includes an index to the species.

**Notes on the introduction of Diprion parasites to Canada**, L. R. FINLAYSON and W. A. REEKS (*Canad. Ent.*, 68 (1936), No. 7, pp. 160–166).—The progress of the introduction of European spruce sawfly (*D. polytomum* Htg.) parasites from England into the Gaspé Peninsula is reported upon.

**Egg placing by *Dibrachys boucheanus* Ratzeburg**, F. L. MARSH (*Canad. Ent.*, 68 (1936), No. 10, pp. 215, 216).—A description is given of the actual placing of the eggs of the cosmopolitan chalcid parasite *D. boucheanus*.

**Notes on the classification of the Aphelinidae, with descriptions of new species**, H. COMPERE (*Calif. Univ. Pubs. Ent.*, 6 (1936), No. 12, pp. [2] + 277–321, figs. 19).—In this systematic contribution 10 genera, including the new genus *Timberlukiella*, and 79 forms are recognized, of which 12 species are described as new. The primary parasites of this family are of more importance as natural enemies of scale insects than are those of any other group except the family Encyrtidae. Their value lies in the ability of certain species to control or partly control some of the most injurious pests of cultivated plants.

**Spinose ear tick in India**, J. S. KINGSTON (*Jour. Roy. Army Vet. Corps*, 7 (1936), No. 3, pp. 142, 143).—A report is made of the finding of the ear tick at Saugor, India, in a 7-year-old Australian remount gelding that had been bred and purchased in Queensland, Australia.

## ANIMAL PRODUCTION

[**Investigations in animal production**] (*U. S. Dept. Agr., Sec. Agr. Rpt.*, 1936, pp. 78–80).—Progress is noted in the development of superior types of pigs through selective breeding and of beef cattle by suitable crosses of native strains with selected foreign breeds introduced for this purpose, methods for satisfactorily wintering range cattle at low cost, studies on quality of meat, and the development of wider uses for whey and other dairy byproducts.

[**Animal husbandry investigations of the Bureau of Animal Industry**] (*U. S. Dept. Agr., Bur. Anim. Indus. Rpt.*, 1936, pp. 7–18, 19, 20).—Results are reported from studies on factors affecting the quality of pork, beef, and lamb; the keeping quality of lards and vegetable oils; the yield and composition of milk from goats; development of apparatus for studies of cross sections and length and crimp of wool and hair fibers; records of performance of beef and dual-purpose cattle; and numerous breeding, feeding, and management studies with beef cattle, sheep, swine, horses, chickens, and turkeys. Much of the work was in cooperation with State experiment stations.

[**Livestock investigations in Arkansas**] (*Arkansas Sta. Bul.* 337 (1936), pp. 37–40).—Results are reported on the supplemental value of tankage, cottonseed meal, and buttermilk to yellow corn for pigs on rye pasture, and fattening pigs on Sudan grass pasture and in dry lot with a period of limited feeding as compared with full feeding for the entire period, both by E. Martin; and on factors affecting the storage quality of eggs, and rice byproducts in the laying ration, both by R. M. Smith.

[**Livestock experiments in Delaware**] (*Delaware Sta. Bul. 203 (1936)*, pp. 17-20).—Additional results are briefly reported on studies previously noted (E. S. R., 74, p. 78), as well as on breeding for high egg production with special reference to the method of selection of breeding males, by A. E. Tomhave and C. W. Mumford.

[**Livestock investigations in Michigan**] (*Michigan Sta. [Blen.] Rpt., 1935-36*, pp. 6-9, 25, 43-45).—Studies with various types of livestock yielded results on the influence of breeding and age on the rate and efficiency of fattening in steers, the comparative carcass quality of helpers v. steers, liberal v. limited rations for the development of draft colts, the optimum allowance of skim milk for growing fattening pigs, alfalfa meal as a protein supplement for pregnant sows, the amounts of roughage desirable for fattening lambs, and winter rations for breeding ewes.

Results of poultry studies are reported on a comparison of electric and coal brooders in the production of winter broilers; the influence of varying amounts and qualities of proteins, minerals, and vitamins in baby chick rations; a comparison of different pasture crops for growing poultry; the effect of various rations on the cost of producing turkeys; and chick metabolism studies with special reference to factors influencing the incidence of perosis.

[**Livestock investigations in Missouri**] (*Missouri Sta. Bul. 370 (1936)*, pp. 8-17, 19-23, 45, 46, 70-73).—Beef cattle investigations reported include pasture v. dry lot for full-feeding yearling steers, by L. A. Weaver, J. E. Comfort, and H. C. Moffett; winter rations for beef calves, by E. A. Trowbridge and Moffett; creep-feeding winter calves, the comparative values of legume hays for wintering native calves, and molasses-alfalfa supplements to grain rations for calves, all by Trowbridge, Comfort, and M. W. Hazen; a comparison of systems of grazing bluegrass pasture, by Comfort and E. M. Brown; and winter barley pasture by Comfort.

Results on fat lamb production are reported by Weaver and A. A. Dyer; rations for brood sows, by A. C. Hogan and S. R. Johnson; rations for weanling pigs, cane molasses in the ration of pregnant sows, and feeding swine on winter barley pasture, all by Weaver; various rations for work horses, by Trowbridge and Moffett; and the composition and relative feeding value of drought-stricken and river-bottom corn fodder and silage, and the value of molasses and other supplements to drought corn fodder for various classes of livestock, by Hogan, Trowbridge, Comfort, and Moffett.

Poultry tests yielded results on the nutritional requirements of poultry, grit in the all-mash chick ration, the normal growth rate of chicks, and the influence of time of hatch on growth, all by H. L. Kempster and E. M. Funk; the feed-purchasing power of the eggs laid by a hen, by Kempster; and temperature changes in eggs, the relation of the length of the incubation period to livability of chicks, and growth of turkeys in confinement, all by Funk.

Reported results of nutrition studies include synthetic rations for chicks, by Hogan; the effect of ultraviolet rays on vitamin B carriers, and anemia caused by deaminized casein, both by Hogan and L. R. Richardson; the nutritional requirements of rabbits and guinea pigs, by Hogan and Johnson; basal metabolism, endogenous nitrogen, creatinine, and neutral sulfur excretions as functions of body weight, by S. Brody, R. C. Proctor, and U. S. Ashworth; and endogenous nitrogen and basal energy relationships during growth, by Ashworth.

[**Investigations with livestock in Montana**] (*Montana Sta. Rpt. 1935*, pp. 11-15, 16-19, 20-22, 42-44).—Beef cattle studies at the main station and the Northern Montana Substation include wintering heifers on a high or low plane

of nutrition, and the relation of the type of bulls to birth weight, weaning weight, and subsequent rate of gain of their progeny.

The sheep studies gave results at the Huntley Substation on the use of beet byproducts in the lamb fattening ration. Dry land pasture studies at Huntley yielded results on the value of various annual and perennial crops as pasture for hogs. Chemical studies yielded information on the occurrence of mineral deficiencies in feeding stuffs, and the possibility of increasing the phosphorus content of feeds through phosphate fertilization.

**The feed value of hay from pure cultivated grasses (English ryegrass, awnless brome grass, and meadow fescue)** [trans. title], W. KIRSCH, E. WENCK, and H. JANTZON (*Biedermanns Zentbl., Abt. B, Tierernähr.*, 8 (1936), No. 3, pp. 261-266; *Eng. abs.*, p. 266).—These three varieties of grasses cultivated in pure stands were harvested, dried on riders, and the feeding value of the cured hay determined by digestion trials with wethers. When reduced to a uniform dry matter content of 85.7 percent the digestible crude protein content and the starch values, respectively, were for brome grass 5.74 and 33.4, ryegrass 5.16 and 39.2, and fescue 6.5 and 35.8. In feeding trials with dairy cattle the fescue proved superior to the other two hays, while the ryegrass imparted a typical bitter flavor to both milk and butter.

**The effect of adding new preservatives for the acidification of green plant material on the composition and nutritive value of the resulting silage** [trans. title], H. NEBELSFK (*Biedermanns Zentbl., Abt. B, Tierernähr.*, 8 (1936), No. 3, pp. 161-185; *Eng. abs.*, p. 185).—This article describes the preparation of red clover silage, acidified with solutions of new proprietary phosphorus compounds designated as Penthesta red ( $\text{SO}_3$ ) and Penthesta green ( $\text{PCl}_5$ ). Both compounds produced satisfactory silage with small losses from fermentation. Metabolism trials with wethers and feeding trials with cattle are reported, showing both lots of silage to be palatable and of satisfactory nutritive value.

**The effect of heat as used in the extraction of soy bean oil upon the nutritive value of the protein of soy bean oil meal**, J. W. HAYWARD, H. STEENBOCK, and G. BOHSTEDT (*Jour. Nutr.*, 11 (1936), No. 3, pp. 219-234).—Employing both the growth method and the nitrogen balance method for arriving at protein values, the Wisconsin Experiment Station has studied the effect of employing different temperatures during the extraction of soybean oil on the protein value of the resulting meal.

Raw soybeans were shown to contain protein of low nutritive value, likewise expeller meal processed at 105° C. for 2 min. or hydraulic meal cooked at 82° for 90 min. Expeller-type meals processed at 112° to 150° for 2.5 min., hydraulic-type meal cooked at 105° to 121° for 90 min., and solvent-extracted meal dried at 98° for 15 min. each contained protein of approximately twice the nutritive value of that in the raw beans or low temperature meals. The increase in nutritive value is partially due to increased digestibility of the protein but more largely to an actual increase in its biological value. This is apparently due to the fact that heat renders some essential protein fraction which is unavailable in the raw bean available for absorption and metabolic use.

**The effect of cystine and casein supplements upon the nutritive value of the protein of raw and heated soy beans**, J. W. HAYWARD, H. STEENBOCK, and G. BOHSTEDT (*Jour. Nutr.*, 12 (1936), No. 3, pp. 275-283).—In further studies on the protein value of soybeans, it is shown that raw soybeans of both the Illini and Herman varieties contained an inefficient protein as measured by the grams of growth in rats per gram of protein consumed. The application of heat, either by autoclaving the raw beans for 1 hr. at 15 lb. pressure or by use of the expeller method of oil extraction wherein the beans are heated to 140° to 150°

C. for 2.5 min., practically doubled the nutritive value of the protein. The addition of 0.3 percent of *l*-cystine to the raw bean diet likewise approximately doubled the nutritive value of the proteins, but a similar addition to the heated bean diet was ineffective in further increasing the protein efficiency. A high level of casein as a supplement to the raw bean ration gave results similar to those obtained from the addition of cystine. This would indicate that cystine or its equivalent exists in the raw soybean in a form unavailable to the animal, and that heating causes the cystine fraction to become available.

**The digestibility of Canadian feeding stuffs: Soybean oil meal, C. J. WATSON, J. C. WOODWARD, W. M. DAVIDSON, G. W. MUIR, and C. H. ROBINSON (*Sci. Agr.*, 17 (1936), No. 1, pp. 22-30; *Fr. abs.*, p. 27).**—This is a report of trials conducted at the Central Experimental Farm, Ottawa, to determine the digestibility of expeller process soybean oil meal, using beef steers as experimental animals. Based on the determination of the digestibility of hay alone and of a hay and soybean oil meal ration, the calculated digestibility of the soybean oil meal was as follows: Dry matter, 86.8 percent, nitrogen 88.3, ether extract 88, crude fiber 111, nitrogen-free extract 83.8, and total carbohydrates 88.7. Compared with linseed meal, the soybean meal contained more digestible protein and more total digestible nutrients per 100 lb. of dry matter and on this basis is worth from \$4 to \$5 per ton more. Data obtained on the digestibility of soybean meal by other workers are shown to be of the same general order as that obtained in this investigation.

**Commercial feeding stuffs, L. S. WALKER and E. F. BOYCE (*Vermont Sta. Bul.* 411 (1936), pp. 47).**—This is the usual report of the analyses for protein, fat, and fiber of 1,975 samples of feeding stuffs collected for official inspection during April 1936 (*E. S. R.*, 75, p. 678).

**[A new toxicant occurring naturally in certain samples of plant food-stuffs.—XIV], The effect of selenium-containing foodstuffs on growth and reproduction of rats at various ages, K. W. FRANKE and V. R. POTTER (*Jour. Nutr.*, 12 (1936), No. 2, pp. 205-214, figs. 3).**—Continuing this series of investigations (*E. S. R.*, 76, pp. 63, 245), groups of white rats were placed on toxic diet No. 582 at 21, 42, 63, 84, 105, and 186 days of age. The average ages of survival for these respective groups were 32, 211, 279, 247, 383, and 512 days. These results indicate a very rapid increase in resistance to the toxicant between 21 and 42 days of age. Rats able to survive the toxic diet for relatively long periods made subnormal growth, the general trend being a sharp drop in weight immediately following the change in diet, then an apparent equilibrium, after which the rats continued at a subnormal and irregular rate of growth until death. All groups showed a distinct loss in reproductive power, with all matings in which both animals were on the toxic diet completely infertile. It is suggested that farm animals approaching maturity may have considerable resistance to toxic grains and yet their growth rate and reproductive capacity may be so affected as to destroy the margin of profit for the livestock feeder.

**Digestibility studies with ruminants, I, II (*Sci. Agr.*, 15 (1935), No. 7, pp. 476-487, *Fr. abs.*, p. 484; 17 (1936), No. 1, pp. 11-21, fig. 1, *Fr. abs.*, p. 19).**—Two series of digestion trials conducted at the Central Experimental Farm, Ottawa, are reported.

**I. Plane of nutrition and digestibility of hay, C. J. Watson, G. W. Muir, and W. M. Davidson.**—Four grade Shorthorn steers were fed a mixed clover and grass hay as a sole diet at levels of 2.5, 4.5, 6, 7.5, and 9 kg per steer daily, digestion trials being conducted at each level of feed intake. At the 2.5-kg level coefficients of digestibility were somewhat lower than at the higher levels, but within the intake range of 4.5 to 9 kg the plane of nutrition did not signifi-

cantly affect the digestibility of the hay, although in certain cases the individual constituents showed slight variation.

II. *Plane of nutrition and digestibility of a hay-barley ration*, C. J. Watson, J. C. Woodward, W. M. Davidson, G. W. Muir, and C. H. Robinson.—In a second similar series of trials four Shorthorn steers were fed a mixed ration of hay and ground barley in equal parts, being fed at levels of 1, 2, 3.25, 4.5, and 5 kg of each per steer daily. In digestion trials covering the entire range of feed intake it is shown that the apparent digestibility of the nitrogen significantly decreased as the plane of nutrition increased, amounting to about 6 absolute percent over the feeding range involved. The digestibility of the nitrogen-free extract also decreased slightly with the increased level of feed intake though it is considered of marginal significance, while the digestibility of dry matter, total organic matter, ether extract, and crude fiber were not significantly affected by the plane of nutrition.

**The effect of hard water on metabolism in experiments with ruminants** [trans. title], R. HÖNIGSCHMID and W. LIEBSCHER (*Landw. Vers. Sta.*, 124 (1936), No. 5-6, pp. 329-344).—This is a report of balance trials with 2.5-year-old wethers on a hay ration which in successive trials received drinking water of normal composition, water rich in calcium sulfate, and water rich in magnesium sulfate. Neither type of hard water adversely affected the digestibility of the organic constituents of the hay. The nitrogen balance was unaffected by the high calcium sulfate content but was markedly depressed by the water rich in magnesium sulfate. The food and water consumption was depressed and irregular when water high in magnesium sulfate was allowed.

**The starch units required for live weight gain in the production ration of growing cattle** [trans. title], G. WIEGNER and S. GRANDJEAN (*Biedermanns Zentbl., Abt. B. Tierernähr.*, 8 (1936), No. 4, pp. 287-299, fig. 1; *Eng. abs.*, p. 299).—In grazing trials with cattle in which pasture returns are evaluated by their estimated feed replacement value, the authors attack the fallacy of accepting a fixed starch value requirement per unit of gain in live weight of cattle (e. g., 2.5 starch values per kilogram of increase in body weight) without regard to age or live weight of the animal.

They show that 1 kg of gain in body fat requires 4 starch values, whereas 1 kg of gain in body protein requires 1.36 starch values. Formulas are presented for estimating the relative requirements for protein and fat production at different stages of growth. As a simplified standard for use in measuring pasture yields with grazing cattle it is proposed that animals be classified into three live weight groups, each with a normal requirement for gain in weight as follows: For cattle up to 250 kg live weight 1.5 starch values per kilogram of gain, from 250 to 450 kg live weight 2 starch values per kilogram of gain, and above 450 kg live weight 2.5 starch values per kilogram of gain.

**Phosphorus deficiency metabolism and food utilization in beef heifers**, M. KLEIBER, H. GOSS, and H. R. GUILBERT (*Jour. Nutr.*, 12 (1936), No. 2, pp. 121-153).—The California Experiment Station has conducted a series of metabolism and respiration trials with beef heifers at various levels of phosphorus intake. When the phosphorus intake was maintained at a level of 0.4 percent of the feed the heifers continued to gain in weight throughout the course of the trial and maintained the inorganic phosphorus content of the blood at about the initial level of 9 mg per 100 cc of serum, whereas heifers on a diet containing only 0.13 percent of phosphorus ceased to grow after 6 mo. They were able to maintain their body weight over a 1-yr. period when the phosphorus intake was reduced to 0.09 percent, but finally lost weight when the phosphorus was further reduced to 0.068 percent. During the course of the

phosphorus deficiency the inorganic phosphorus of the blood was reduced from the initial level of 9 mg per 100 cc to 3.9 mg. These animals showed a decreased appetite and developed bone chewing and coprophagia. The phosphorus deficiency did not affect body temperature, digestibility or metabolizability of the food energy, the respiratory quotient, or the level of fasting katabolism. However, it decreased the partial efficiency of energy utilization and also the efficiency of the food protein for sparing body protein.

**Experiments at Craibstone on wintering cattle inside and outside, 1928-35.** W. M. FINDLAY (*Scot. Jour. Agr.*, 19 (1936), No. 2, pp. 115-130).—In a series of trials conducted by the North of Scotland College of Agriculture and extending over a 7-yr. period, similar lots of feeder cattle were wintered in the open with access to an open shed and under constant confinement in the barn. Turnips and straw were fed as the only ration in some trials, while in others some supplementary concentrate was fed. In certain trials the two lots were subdivided, one-half of the cattle in the barn being tied while the others remained loose in the pens, and in the outside group one-half was confined in courts while the other half had access to open fields.

In each trial the group in the open made greater total gains during the winter period, showing particular superiority during the latter half of the season. The method of handling apparently had little influence on the in-barn group, while of the outside groups those allowed run of the field excelled those confined in courts. The rate of winter feeding tended to affect the rate of gains during the subsequent summer grazing period. On the whole the open-field lots made the greatest combined winter and summer gain, were ready for the market at an earlier date, and gave a higher dressing percentage. There was a marked variation in the response of different individuals kept under the same conditions, indicating the desirability of good feeder stock.

**Differentiation of fresh cattle and carabao meat by hemagglutination.** R. A. ACEVEDO (*Philippine Jour. Anim. Indus.*, 3 (1936), No. 4, pp. 251-262, pl. 1, fig. 1).—This study was actuated by the need of a test for differentiating between fresh beef and carabao meat as a means of protecting the public against the unscrupulous sale of the latter as beef. A technic is described for the preparation of anticarabao hemagglutinins which permitted the differentiation with a high degree of efficiency.

**The influence of calcium salts and hay on the calcium and phosphorus metabolism of sheep fed mineral acid silage** [trans. title], F. SCHNEFF (*Biedermanns Zentbl., Abt. B, Tierernähr.*, 8 (1936), No. 4, pp. 300-339, figs. 8; *Eng. abs.*, pp. 338, 339).—The extensive feeding of mineral acid silage to sheep resulted in a decreased appetite and negative balances for both calcium and phosphorus. The addition of calcium salts either as a carbonate or phosphate corrected the negative balances but did not improve the appetite of the animals. The addition of good clover hay equivalent to from one-third to one-half the dry matter in the ration corrected the negative calcium and phosphorus balances and markedly improved the appetite. The pH of the urine was decreased on the silage ration, negative calcium balances ordinarily being accompanied by a decreasing pH of the urine. No differences could be detected between the silages acidulated with hydrochloric acid or sulfuric acid, either as regards the quality of the silage or its effect on the metabolism of the animals.

**Production and feeding of early lambs.** W. E. HUNT (*Maryland Sta. Bul.* 398 (1936), pp. 37-75, figs. 5).—The results of two studies are presented.

**I. A comparison of Southdown and Ryeland rams as sires of early lambs.**—In an attempt to produce early lambs having desirable fattening qualities under Maryland conditions purebred Ryeland and Southdown rams were mated with

Dorset × grade Delaine-Merino ewes. All lambs by the Southdown ram were dropped between November 22 and January 7, while lambs by the Ryeland ram were dropped between December 9 and February 17. There was no significant difference in the average birth weight of the two lots of lambs. The 15 Southdown cross lambs averaged 46 lb. in weight at 64 days of age, and the 20 Ryeland cross lambs averaged 48 lb. at 70 days. The slight difference in average market grade in favor of the Southdown lambs is probably attributable to the higher proportion of twins in the Ryeland group. Representative lambs from each lot subjected to slaughter tests were practically identical in average dressing percentage and carcass grade. The Ryeland lambs had slightly longer and more open fleeces and sheared slightly heavier than the Southdown lot. Yearling ewes from the former group averaged 140.9 lb. as compared with 118.6 lb. for yearling ewes of the latter group.

II. *Fishmeal and cottonseed meal as protein supplements for ewes and their creep-fed early lambs.*—Three feeding trials comparing various rations are reported. In trial 1, involving two lots of ewes and their lambs, alfalfa hay was fed ad libitum to both groups, one of which received shelled corn as the sole concentrate ration and the other a mixture of 9 parts of shelled corn and 1 part of menhaden fishmeal. At 70 days of age the lambs in the former group averaged 2.9 percent more in weight than those in the latter group. In the second trial, involving three lots of ewes and their lambs, alfalfa hay was fed in limited quantity ( $2\frac{1}{4}$  to  $2\frac{1}{2}$  lb. per ewe daily) in the evenings and a similar quantity of timothy was offered in the mornings. Lot 1 received only shelled corn, lot 2 a mixture of 87 parts of shelled corn and 13 parts of cottonseed meal, and lot 3 a mixture of 9 parts of corn and 1 part of menhaden fishmeal. At 70 days of age the lambs in lots 2 and 3 averaged 10 and 11 percent, respectively, more than those in lot 1 which received no protein supplement. In trial 3, in which two lots of ewes and their lambs were used, roughage was fed as in the second trial. Lot 1 received a mixture of 7 parts of shelled corn and 1 part of cottonseed meal and lot 2 a mixture of 10 parts of shelled corn and 1 part of menhaden fishmeal. The lambs in lot 1 averaged 65 percent greater gains than those in lot 2, and the ewes in lot 1 gained 2.9 lb. per ewe as compared with a gain of 2.1 lb. for those in lot 2. The results indicate that when roughage is half leguminous and half nonleguminous satisfactory results cannot be obtained without supplying some source of high protein supplement in the ration. In all these trials the lambs on the corn-fishmeal ration consumed their feed readily and made excellent gains to 5 or 6 weeks of age but beyond this age they showed a marked dislike for the ration and feed consumption and growth rate fell below that of the other groups.

**Lamb feeding in southern Alberta, W. H. FAIRFIELD and K. RASMUSSEN** (*Canada Dept. Agr. Pub. 478 (1936), pp. 52, figs. 14*).—This publication presents a summary of 18 years' experimentation in the feeding of range lambs for market. A total of 64 feeding trials has been conducted, and 37 different rations have been tested. Alfalfa is the only feeding stuff employed consistently in all trials. Variations in the rations included the feeding of oats, barley, and wheat, each singly and in various combinations, both ground and unground, and also the use of corn silage, sunflower silage, beet pulp, roots, molasses, and sheaf oats as other ingredients in the rations.

Full grain feeding was ordinarily more profitable than a two-thirds grain ration and was always definitely superior to a one-half grain ration, while self-feeding did not prove generally practical. The average daily gain for all trials was 0.32 lb. per lamb, while an average gain above 0.4 lb. daily was

frequently attained. The average rate of mortality for all trials was 0.75 percent. It is concluded that the finishing of lambs over a long term of years has provided a satisfactory profit over feed costs and interest charges. Appended are brief sections on general farm feeding practices and the utilization of the forest reserve for summer sheep range.

**Comparative study on the productivity and adaptability of Berkshire, Duroc-Jersey, and Poland China pigs to local conditions**, G. MIÑANO (*Philippine Jour. Anim. Indus.*, 3 (1936), No. 4, pp. 281-288).—This is a study of the general adaptability of these three breeds of swine to Philippine conditions. Particular reference is made to the productivity, average length of productive life, resistance to common diseases, and general mortality. It is concluded that the Poland China is best adapted to local conditions, while the Duroc-Jersey and the Berkshire are about equal.

**A contribution on the conducting of swine performance tests** [trans. title], J. SCHMIDT and E. LAUPRECHT (*Zuchtungskunde*, 10 (1935), No. 1, pp. 11-17).—In this experiment, involving two litters of nine pigs each, the pigs were fed individually to test the reliability of selecting two pigs from a litter as representative of the litter in a performance test. By making all possible combinations of one male and one female pig for both litters it is shown that either the heaviest pair or the smallest pair is less suitable than pairs consisting of pigs near the average weight for the litter. The results indicate that two average pigs from a litter may be satisfactorily used to measure the fattening ability of the litter.

**Rice meal as a partial substitute for farm grains in the hog ration**, E. W. CRAMPTON (*Sci. Agr.*, 16 (1936), No. 9, pp. 489-494; *Fr. abs.*, p. 494).—This is a report of a study conducted at Macdonald College in which rice feed was fed to growing and fattening pigs at 25, 50, and 75 percent levels in a basal ration also containing barley and/or oats. The basal ration was supplemented with 15 percent of mixed protein concentrate during the growing period (42 days) and 10 percent during the subsequent fattening period.

Quite satisfactory results were obtained from all rations during the growing period, although there was a tendency for feed consumption to decline somewhat near the end of the period for all lots receiving rice feed, particularly those at the highest level. Because of the tendency for a high level of rice feed to produce soft carcasses and also because of its adverse effect on feed consumption, it is recommended that the fattening ration contain not more than 25 percent of rice feed. Barley proved superior to oats as an ingredient in the basal ration.

**Feeding trials with raw and cooked soybeans in the rations of pigs** [trans. title], V. HORN and E. MÜHL (*Biedermanns Zentbl., Abt. B, Tierernähr.*, 8 (1936), No. 3, pp. 230-237; *Eng. abs.*, p. 237).—In the fattening trials reported a basal ration of steamed potatoes supplemented with barley, meat meal, fish meal, and chalk was fed the check group, while in the ration of two experimental groups a part of the barley and fish meal was replaced by ground raw soybeans and boiled whole soybeans, respectively. Under these conditions, where an ample supply of animal protein was provided in the meat meal the soybean rations produced practically as good gains as the check ration and at less cost. The cooked beans proved superior to the ground raw beans, although it is a question whether the difference was sufficient to justify the extra cost involved in cooking. When the intake of soybeans did not exceed 200 g per animal daily the quality of the fat was considered satisfactory.

**Some studies on the causes of soft bacon**, R. D. SINCLAIR (*Sci. Agr.*, 17 (1936), No. 1, pp. 31-41; *Fr. abs.*, pp. 40, 41).—In a report of studies at the University of Alberta it appears that none of a rather wide range of feeding con-

ditions described were directly responsible for the occurrence of soft carcasses in bacon pigs, although a high percentage of oats in the ration tended to increase the iodine number of the fat. Pigs slaughtered at minimum, optimum, and maximum live weights permissible for export bacon yielded carcasses of satisfactory firmness. It is shown that pigs fed during the winter months yielded fat of higher iodine number than that from summer-fed pigs, indicating a seasonal relationship to hardness of fat. Pigs allowed to become unthrifty and to make slow gains are more likely to be "soft" than those in a thrifty, rapid-growing condition. Individuals under the same conditions of feeding and management showed marked variation in degree of softness, suggesting the possibility of breeding for firmness of fat in the carcass.

[Poultry Science Association, twenty-eighth annual meeting] (*Poultry Sci.*, 15 (1936), No. 5, pp. 411-432).—Following are listed the titles of papers presented before the annual meeting held at Virginia Polytechnic Institute, August 4-7, 1936, for which brief abstracts are presented: How Shall We Build Poultry Disease Control Programs in the Future? by R. E. Jones (pp. 411, 412); Labor Efficiency on Massachusetts Poultry Farms, by G. T. Klein (p. 412); Observations on the Mechanics of Ovulation in the Fowl, by R. E. Phillips (p. 413); Sterility in the Fowl, by F. R. Sampson and D. C. Warren (pp. 413, 414); The Relation of Some Egg Quality Factors to Hatchability, by E. M. Funk (p. 414); The Association of Certain Measures of Interior Egg Quality With Hatchability, by G. O. Hall and A. Van Wagenen (p. 414); Hatchability as Related to Season and Hour of Laying, by F. A. Hays (p. 414); A Six-point General Sanitation Program for Poultry, by P. W. Allen (pp. 414, 415); Differentiation of Paralysis in Chicks, by E. Jungherr (pp. 415, 416); Studies of the Clinical Manifestations and Transmissibility of Infectious Coryza of Chickens, by J. R. Beach and O. W. Schalm (p. 416); Studies of Infectious Coryza of Chickens With Special Reference to Its Etiology, by O. W. Schalm and J. R. Beach (p. 416); Studies in Coccidiosis in Chickens: Calcium Carbonate Additions and Coccidia, by C. E. Holmes, C. A. Herrick, and G. L. Ott (pp. 416, 417); The Control of Environmental Conditions for Egg Production, by F. L. Fairbanks (p. 417); The Effect of Environmental Conditions on Winter Egg Production, by J. H. Bruckner (pp. 417, 418); Problems in Creating a General Poultry Housing Plan Service, by W. M. Vernon (p. 418); Relation of Housing to Respiratory Problems, by C. D. Carpenter (p. 418); Texas Poultry House Problems, by D. H. Reid (pp. 418, 419); Problems in the Housing of Poultry, by W. C. Sanctuary (p. 419); Genetic Differences in Eight-week Weight and Feathering, by R. G. Jaap and L. Morris (pp. 419, 420); The Inheritance of Shank Color in Chickens, by P. D. Sturkie, C. B. Godbey, and R. M. Sherwood (p. 420); A Study of the Variability of Body Temperature in the Normal Chick, by W. F. Lamoreaux and F. B. Hutt (p. 420); Relationship of Sex to Feather Development in the Chick Embryo, by M. H. Radi and M. T. Harman (p. 421); The Incidence of Blindness and Paralysis According to Family, by C. W. Upp and B. A. Tower (p. 421); Some Trends in Poultry Housing, by D. C. Kennard (pp. 421, 422); The Connecticut 24' x 24' Poultry House, by R. E. Jones (p. 422); The Effect of Feeding Grit on Digestibility in the Domestic Fowl, by J. C. Fritz (pp. 422, 423); Protein Levels in the Fattening Ration as Influencing the Composition of the Thigh Muscle With Different Ages of Poultry Meat Stock, by W. A. and A. J. G. Maw, R. Holcomb, and L. H. Bemont (p. 423); Some Factors Influencing the Blood Calcium of Laying Hens, by H. J. Deobald, J. B. Christiansen, E. B. Hart, and J. G. Halpin (p. 423); Constituents of Wheat Gray Shorts Which Prevent Slipped Tendon, by R. M. Sherwood and G. S. Fraps (p. 424); Factors Producing and Preventing Perosis, by V. G. Heller and R. Penquite (p. 424); Percentage of Unsalable

and Unusable Eggs, by J. C. Graham (p. 424); The Effect of Various Storage Conditions Upon the Ammonia Nitrogen Content of Eggs, by P. J. Schaible, J. A. Davidson, and S. L. Bandemer (pp. 424, 425); Vitamin A Requirements of Growing Chicks.—II, Pilchard Oil as a Source of Vitamin A, by J. Biely and W. Chalmers (p. 425); Vitamin A Content of Pilchard Oil, by H. I. Milne (pp. 425, 426); Further Studies on the Vitamin A Requirements of Chicks, by W. O. Wilson, C. H. Schroeder, and W. A. Higgins (p. 426); Vitamin D Requirements of Growing Chicks as Affected by the Calcium Content of the Ration, by J. R. Couch, G. S. Fraps, and R. M. Sherwood (pp. 426, 427); Vitamin G Studies: Flavines in Chick Nutrition, by R. M. Bethke, P. R. Record, and O. H. M. Wilder (p. 427); The Vitamin G Requirements of Laying Hens, by H. J. Davis, L. C. Norris, and G. F. Heuser (pp. 427, 428); Quality in Poultry Meat, by F. P. Jeffrey (p. 429); Variations in Egg Quality Characters in Certain Breeds, Varieties, and Strains of Chickens, by A. Van Wagenen, G. O. Hall, and H. S. Wilgus, Jr. (pp. 429, 430); A Method for Determining the Sex of a Turkey From the Hatching to Maturity, by J. C. Hammond and S. J. Marsden (p. 431); and The Modifying Influence of Environment Upon Growth and Sexual Development, by E. W. Callenbach (p. 432).

The normal growth of chickens under normal conditions, H. L. KEMPSTER and J. E. PARKER (*Missouri Sta. Res. Bul.* 247 (1936), pp. 47, figs. 6).—This study is based on observed growth rate of over five thousand chicks of Single Comb White Leghorn, White Rock, and Single Comb Rhode Island Red breeds hatched at the State Poultry Experiment Station farm over a 6 yr. period and reared under favorable (normal) conditions. Pullets of these breeds averaged 39.7, 41, and 41.5 g in weight, respectively, at hatching; 184, 179.2, and 186.2 g at 4 weeks; and 1,587.3, 2,290.3, and 2,480.5 g at 40 weeks of age. The greatest gains during any 4-week interval were in the ninth- to twelfth-week period for each of the three breeds. Differences in growth rate of males and females became apparent at 8 weeks of age, and at 20 weeks the White Leghorn, White Rock, and Rhode Island Red pullets averaged, respectively, 77.2, 78.2, and 80.8 percent as much as the cockerels. No significant relation was found between the age of the hens and the weight of their pullet progeny at 40 weeks of age. Early-hatched chicks made above normal gains up to 20 weeks but below normal growth thereafter, whereas the late-hatched chicks made subnormal gains up to 20 weeks but above normal growth as they approached maturity. These variations in growth rates of early- and late-hatched chicks appear to be associated with certain climatic conditions, particularly average maximum and mean temperatures for the periods.

Potatoes as a feed for chickens, M. J. KLOOSTER and C. G. CARD (*Michigan Sta. Quart. Bul.*, 19 (1936), No. 2, pp. 104-108).—In feeding trials with laying hens raw and cooked potatoes were each fed free choice and also were incorporated in the mash ration replacing one-half the corn. Raw potatoes were less palatable than cooked potatoes. Hens maintained their body weight on either ration, but those receiving raw potatoes did not maintain satisfactory egg production. However, the group receiving cooked potatoes compared favorably with the check lot in this respect. Excessive amounts of either raw or cooked potatoes had a laxative effect on the laying hens.

In trials with growing chicks substituting dried cooked potatoes or dried raw potatoes for one-half of the yellow corn in the mash ration or replacing all the corn with dried cooked potatoes resulted in more rapid gains than were obtained in the check lot. However, replacing all the corn with dried raw potatoes resulted in greatly retarded growth. Neither of the dried potato diets exerted a laxative effect on the chicks.

**The quantities of vitamin A required by growing chicks, R. M. SHEERWOOD and G. S. FRAPS (*Texas Sta. Bul. 528 (1936), pp. 15*).—**The chicks used in this study were hatched from eggs laid by hens receiving experimental rations of varying vitamin A potency as previously noted (E. S. R., 72, p. 238). Chicks produced from hens receiving 325 Sherman-Munsell units of vitamin A per 100 g of feed had an average mortality of 64.4 percent, whereas chicks from hens receiving either 495 or 655 units per 100 g of feed had a mortality of 38.5 percent under the same conditions. Feeding liberal amounts of vitamin A to the chicks did not overcome the effect of the deficiency in the hens' ration. (Chicks hatched from eggs rich in vitamin A have a lower vitamin A requirement for normal growth than chicks from eggs low in this vitamin, 125 units of A per 100 g of feed proving generally adequate for the former group whereas the latter required much larger amounts, possibly as much as 300 units per 100 g of feed.

**Effect of different sources of vitamin D on the laying bird.—II, Storage of vitamin D in the egg and chick and mineral composition of the mature embryo, R. M. BETHKE, P. R. RECORD, O. H. M. WILDER, and C. H. KICK (*Poultry Sci., 15 (1936), No. 4, pp. 336-344, fig. 1*).—**The last sentence of the abstract (E. S. R., 73, p. 234) should read "Vitamin D as irradiated ergosterol was less efficiently transferred to the egg than equivalent rat units from cod-liver oil, with evidence that the vitamin D occurring in the egg is in the same biological form as that fed to the hen."

**The relation of vitamin G to the hatchability of hens' eggs, R. M. BETHKE, P. R. RECORD, and D. C. KENNARD (*Jour. Nutr., 12 (1936), No. 3, pp. 297-307*).—**In a study at the Ohio Experiment Station it is shown that White Leghorn hens receiving a basal ration containing ground wheat, wheat bran, yellow corn, meat scrap, bonemeal, salt, cod-liver oil, and oystershell produced eggs of relatively low hatchability, while the inclusion of either alfalfa leaf meal, dried skim milk, dried whey, autoclaved yeast, dried liver, or wheat germ in the ration caused an increase in hatchability of the eggs produced. Similar results were obtained when menhaden fish meal or casein replaced meat scrap in the basal ration. These results together with the observation that the factor or factors could be extracted from alfalfa leaf meal, dried liver, or dried whey indicated that increase in hatchability was not associated with protein. Data presented show that the factor or factors were not associated with vitamin B<sub>4</sub> or vitamin E but evidently were due to vitamin G (B<sub>2</sub> complex), and that this factor is essential for the normal embryonic development of the chick.

**The effect of the ration of the hen on the vitamin G content of eggs with observations on the distribution of vitamin B and G in normal eggs, R. M. BETHKE, P. R. RECORD, and F. W. WILDER (*Jour. Nutr., 12 (1936), No. 3, pp. 309-320, figs. 4*).—**In further studies on the distribution of vitamins B and G in eggs, it is indicated that vitamin B is present in the yolk of eggs but not in the egg white, while vitamin G is contained in both the white and yolk, and on a fresh egg basis is somewhat more potent in the latter. The inclusion of dried skim milk, dried whey, autoclaved yeast, dried liver, and certain fish meals in rations low in vitamin G definitely increased the vitamin G content of the egg produced. Evidence is also presented confirming the previous conclusion that hatchability of eggs is related to their vitamin G content.

**Factors influencing the incidence of dietary hemorrhagic disease in chicks, H. J. ALMQUIST and E. L. R. STOKSTAD (*Jour. Nutr., 12 (1936), No. 4, pp. 329-335, figs. 2*).—**Continuing the investigation on the dietary hemorrhagic disease in chicks (E. S. R., 74, p. 688), it is shown that the antihemorrhagic vitamin is present in the fecal matter of chicks on a diet containing none of this

vitamin. Its synthesis in the lower intestinal tract and also in droppings allowed to stand for 24 hr. has been demonstrated. It is evident that in studying this vitamin test chicks must not have access to their droppings. It is also shown that the antihemorrhagic vitamin is transferred from the diet of the hen to her chicks, so it is necessary to eliminate so far as possible all substances containing this vitamin from the ration of hens producing chicks for use in this study. The vitamin is present in egg yolk but not in egg albumin. It does not seem to be stored in the livers of young chicks raised on normal diets.

**The rôle of certain inorganic elements in the cause and prevention of perosis**, H. S. WILGUS, JR., L. C. NORRIS, and G. F. HEUSER (*Science*, 84 (1936), No. 2176, pp. 252, 253).—This report from the [New York] Cornell Experiment Station indicates that additions of either chemically pure calcium carbonate, calcium hydroxide, calcium chloride, mono-, di-, and tricalcium phosphate, or monosodium phosphate aggravated the occurrence of perosis in young chicks to about the same extent as bonemeal. However, the addition of a technical grade of monocalcium phosphate to the ration exerted a curative rather than a causative action on this ailment. Analysis revealed the presence of considerable manganese and also some iron and aluminum in this product. The addition of minimal amounts of manganese to the ration proved effective in preventing perosis at relatively high levels of calcium and phosphorus intake. Additions of small amounts of iron, aluminum, and zinc also exerted some beneficial effect. It is concluded that perosis is due to the lack of certain inorganic elements, notably manganese, while excess calcium and phosphorus aggravate its occurrence.

**Egg farming**, W. C. THOMPSON (*New York: Orange Judd Pub. Co., 1936, pp. 335, pls. 2, figs. 70*).—This is a practical manual dealing with the production of eggs and poultry for market as a profitable business enterprise. Successive chapters discuss the modern industry of egg farming in the United States; the economically useful types, breeds, and varieties of domestic poultry; poultry laying flock improvement; maintaining the health and productivity of well-bred laying stock; methods and practices of chick production and rearing on the egg farm; the economical and efficient housing of young and adult poultry; a practical feeding program for the adult poultry flocks on the modern egg farm; and the handling, grading, packaging, and distribution of table eggs.

**Turkey production**, A. J. MACDONALD and M. S. MILLER (*Harper Adams Agr. Col. Bul. 12* (1936), pp. 7, fig. 1).—This bulletin deals primarily with the results obtained in rearing turkey poults from 7 to 28 weeks of age under intensive and extensive conditions.

In a trial including poults of both the Black Norfolk and American Bronze breeds, the lots received identical rations except that the intensive group received marrow stem kale as a succulent feed whereas the extensive group had access to good grass runs. At the end of the fattening period there was no significant difference in the weight or the quality of the carcass of the birds reared under the two systems, but the mortality rate amounted to 7.9 percent in the intensive lot and 36 percent in the extensive group. Blackhead infection was the primary cause of death in the latter but was not observed in the former group, indicating that intensive rearing is a satisfactory method of combating this disease. Treatment of blackhead-infected birds with chlorsan or carbon tetrachloride was ineffective for control of this disease.

## DAIRY FARMING—DAIRYING

[Investigations with dairy cattle and dairy products in Michigan] (*Michigan Sta. [Bien.] Rpt. 1935-36, pp. 12, 13, 14, 22, 23, 25-27*).—Results are reported from studies with dairy cattle on the value of alfalfa hay in the ration; the

comparative value of alfalfa hay and alfalfa-molasses silage; the effect of supplementing a low phosphorus alfalfa ration with bonemeal on growth, reproduction, and milk production; the feeding of concentrates alone to ruminants; the relation of magnesium, phosphorus, and vitamin D in the ration; and vitamin D requirements of dairy calves.

Studies with dairy products yielded results on the vitamin A content of butterfat under various conditions; the effect of heat on certain chemical and physical properties of milk; and the influence of mastitis infection on the methylene blue reduction test and the relation of this test to bacterial plate counts in milk.

[Investigations with dairy cattle and dairy products in Missouri] (*Missouri Sta. Bul.* 370 (1936), pp. 34-36, 42-45, 46, 47, 49).—Dairy cattle investigations yielded results on the effect of increasing the interval between milkings and also the effect of injections of sterile solutions, milk, and oxygen into the udder on the yield and composition of milk, both by C. W. Turner and E. R. Garrison; the influence of the thyroid upon metabolism and milk secretion, by Turner and R. P. Reece; the composition of colostrum of the goat and changes which occur as the milk becomes normal, by Turner and A. J. Bergman; the effect of lactation on the blood sugar of dairy cows, and the cellular constituents of the blood as influenced by growth and lactation, both by Turner and H. A. Herman; milk supplemented only with minerals and vitamins as the sole diet for calves, by Herman S. Brody, and A. C. Ragsdale; the energetic efficiency of milk production and the influence of live weight thereon, by Ragsdale, Brody, and R. C. Proctor; and the effect of short-time gestations upon milk yield, the occurrence of polythelia in dairy cattle, and the butterfat production of cows possessing supernumeraries, all by Gifford.

Breeding, feeding, and management studies at the Hatch Experiment Farm are noted by Ragsdale and C. W. McIntyre.

Dairy products studies gave information on the crystalline structure of ice cream, by W. H. E. Reid and R. F. Reitemeier; the relation of air conditioning to the quality and crystalline structure of frozen desserts, by Reid and D. J. Gandhi; and a photomicrographic study of some of the factors affecting the physical properties of butter, by Reid.

[Dairy cattle investigations in Montana] (*Montana Sta. Rpt.* 1935, p. 19).—Results at the Huntley Substation gave further information on the economy of milk production when high quality roughages are fed as a sole ration to milking cows and the value of using high grade purebred sires.

Alfalfa-molasses silage vs. alfalfa hay as a roughage for lactating dairy cows, R. F. HORWOOD and J. G. WELLS, JR. (*Michigan Sta. Quart. Bul.*, 19 (1936), No. 2, pp. 100-104).—In a trial at the Upper Peninsular Substation second-cutting alfalfa ensiled in a fresh unwillited condition with the addition of 30 lb. of molasses per ton of alfalfa was compared with second-cutting field-cured alfalfa hay in a double reversal feeding trial with six milking cows. Either the alfalfa silage or alfalfa hay was fed as the sole roughage ration, and ground barley was the only concentrate fed each group. The alfalfa silage was readily consumed, and a portion of the material ensiled in an unchopped condition proved even more palatable than the chopped silage. The cows while on the silage ration consumed 35 lb. more digestible protein but 451 lb. less total digestible nutrients, produced 310 lb. more 4-percent milk, and gained 46 lb. less in live weight than when on the hay ration. No differences were noted in the general health of the two groups of cows. The alfalfa silage was found to have a relatively low carotene content, and the carotene content of butterfat samples averaged slightly less on the silage ration than on the hay ration.

**Alfalfa silage**, W. B. NEVENS and A. F. KUHLMAN (*Jour. Dairy Sci.*, 19 (1936), No. 9, pp. 611-617).—The Illinois Experiment Station has conducted a series of experiments in which freshly cut alfalfa was ensiled in small experimental silos. Different lots containing 23, 25, 27, 32, and 39 percent of dry matter, respectively, when ensiled without preservative yielded silage having good keeping quality; the higher percentage of spoilage at 39 percent dry matter level would indicate that this is about the upper limit permissible for successfully ensiling alfalfa alone. The addition of from 1 to 5 percent of whey powder caused an increase in acidity of the silage, roughly in proportion to the amount of powder added. Molasses and the lactic acid and *Bacillus bulgaricus* cultures used each caused some increase in acid production, though none of these were as effective as whey powder in this respect. The mixing of corn and alfalfa resulted in a good quality silage. Ensiled unchopped alfalfa did not keep as well as the chopped material under the conditions of this experiment. In a brief feeding trial with milking cows the alfalfa silage proved palatable and appeared to have a feeding value comparable with that of corn silage, though having a more pronounced laxative effect on the animals than corn silage.

**Vitamin A activity of third cutting alfalfa hay as affected by methods of curing**, E. WOODS, F. W. ATKESON, H. WELLHOUSEN, and R. F. JOHNSON (*Jour. Dairy Sci.*, 19 (1936), No. 9, pp. 581-596, figs. 4).—Employing methods for vitamin A assay as previously noted (E. S. R., 74, p. 677), the Idaho Experiment Station found that a fresh sample of cock-cured third-cutting alfalfa hay contained  $308 \pm 13$  rat units of vitamin A activity per gram. The leaves and stems of this hay contained  $483 \pm 34$  and  $121 \pm 7$  rat units, respectively. On this basis approximately 85 percent of the vitamin A activity was in the leaves. Another sample of this same hay ground and held at room temperature in diffused light for about 4 mo. contained  $233 \pm 20$  rat units, indicating a loss due to storage of about 24 percent. Two other lots of the hay cured in the swath for 1 and 3 days, respectively, then cock-cured and later sweated in the stock contained  $144 \pm 10$  and  $116 \pm 9$  rat units. Compared with the stored sample there was an apparent loss of about 28 percent in vitamin A activity due to sweating in the stack and a further loss of approximately 20 percent due to 2 additional days curing in the swath.

These results indicate that under reasonably good conditions as commonly encountered in hay curing in this area alfalfa hay should contain 100 or more rat units of vitamin A per gram, which would represent a potent source of this vitamin for dairy cattle under winter feeding conditions and should result in dairy products with a high vitamin A value.

**Comparison of the feeding value of steam dried and flame dried menhaden fish meal**, M. H. BERRY and J. R. MANNING (*Jour. Dairy Sci.*, 19 (1936), No. 10, pp. 663-669).—This is a report of two separate feeding trials conducted at the Maryland Experiment Station in each of which two groups of yearling heifers were fed steam-dried meal and flame-dried meal, respectively, as 10 percent of their total ration. The remainder of the ration in each case consisted of clover hay 60 percent, yellow corn 20, and wheat bran 10 percent. The two meals were apparently equal in palatability. In each trial slightly more rapid growth resulted from the flame-dried meal ration, although these differences are not considered significant and it is concluded that the two are practically equal in growth-promoting properties at the level fed.

**Ground versus unground grain for lactating dairy cows**, A. L. DARNELL and O. C. CORELAND (*Texas Sta. Bul.* 530 (1936), pp. 25).—This bulletin reports the results of double reversal feeding trials with dairy cows to compare the

value of whole v. ground corn, whole v. ground oats, whole v. ground milo, and whole v. ground barley. In each experiment there was a greater consumption of concentrates by both groups of cows during the periods they were receiving ground grain in spite of efforts to obtain approximately equal consumption of the two rations. Much more whole corn was refused by the cows than any other of the whole grains, followed in order by milo, barley, and oats, indicating that the hardness and also the size of the grains had an influence on their palatability. Greater milk production was obtained during the periods of ground grain feeding in each instance. On the basis of the productive energy exchange the greater amount of milk produced during the period of ground grain feeding is largely accounted for by the greater consumption of concentrates.

Analyses of feed consumption and milk production records indicate that it is more profitable to grind grain for high-producing than for low-producing cows, this condition being more pronounced in the case of corn and barley than for oats or milo. The percentage of whole grain masticated was influenced more by the individuality of the animals than by the kind of grain fed. However, on the average, cows masticated a greater percentage of whole corn than of whole milo. Chemical analyses of grains before and after feeding showed that the cow obtained little if any energy from the unmasticated grain during its passage through the digestive tract.

**The effect of feeding cacao shell to cows on the vitamin D content of butter (milk),** S. K. KON and K. M. HENRY (*Biochem. Jour.*, 29 (1935), No. 9, pp. 2051-2056).—In experiments at the National Institute for Research in Dairying, it is shown that feeding 2 lb. of cacao shells daily to milking cows (equivalent to 32,000 international units of vitamin D) for 1 mo. resulted in increasing the vitamin D content of the milk and butterfat from winter to summer levels.

**The calcium and inorganic phosphorus content of the blood plasma of normal dairy cattle,** J. R. HAAG and I. R. JONES (*Jour. Biol. Chem.*, 110 (1935), No. 2, pp. 439-441).—The Oregon Experiment Station has determined the calcium and phosphorus content of the blood plasma of a considerable number of normal dairy cattle of various ages. The calcium value of the blood plasma ranged from 8.05 to 11.48 mg per 100 cc, with an average of 9.99 mg, 92.5 percent of the values falling between 9 and 11 mg per 100 cc. The inorganic phosphorus values were less constant and appeared to follow a gradual decline with increase in age, ranging from an average of 7.74 mg per 100 cc in calves under 6 mo. of age to an average of 5.18 mg for all animals over 4 yr. of age.

**Studies on the chemical composition of the blood of dairy cattle.—II, The effect of phosphorus intake on the calcium and inorganic phosphorus content of whole blood of dairy heifers during the period of first gestation and lactation,** A. H. VAN LANDINGHAM, H. O. HENDERSON, and G. A. BOWLING (*Jour. Dairy Sci.*, 19 (1936), No. 9, pp. 597-609, fig. 1).—Continuing this line of investigation (E. S. R., 74, p. 247), the authors have studied the effect of two levels of phosphorus intake on the calcium and inorganic phosphorus content of the blood of Holstein heifers during their first gestation and lactation periods. The rations for the two groups were composed of natural feeding stuffs without phosphorus supplement and were of similar nutritive value. The average daily intake of calcium and phosphorus, respectively, per head was 18.8 and 11.8 g for the low phosphorus group and 20.6 and 28.4 g for the high phosphorus group.

Based on blood analyses made at 4-week intervals throughout the gestation and lactation periods, it appeared that the lower level of phosphorus intake (equivalent to 1.2 g per 100 lb. of live weight) was sufficient to maintain the

inorganic phosphorus of the blood at approximately normal levels during gestation. Both groups showed a drop in blood phosphorus immediately following parturition, which was much more pronounced in the low phosphorus group. Milk production combined with low phosphorus intake resulted in a lower inorganic phosphorus blood level for this group until near the end of the milking period.

It appears that within the range of milk production encountered the phosphorus in the feed should exceed the phosphorus in the milk by 9 to 10 g per 1,000 lb. of body weight daily to maintain a normal inorganic phosphorus level in the blood. The calcium content of the blood was not appreciably affected by any of the conditions entering into this trial.

**Influence of an increase in base intake on the acid base balance, health, and production of milk cows** [trans. title], E. BROUWER (*Dept. Landb. en Vissch.* [Netherlands], *Verslag. Landbouwk. Onderzoek.*, No. 41 C (1935), pp. 521-560, figs. 2; *Ger. abs.*, pp. 559, 560).—This article presents an extensive review of the literature on the effect of excess bases in the ration on the well-being of the animal. In experiments with healthy milk cows it is shown that the presence of considerable excess of base in the ration did not noticeably disturb the health or production of the animals. The addition of calcium or sodium carbonate to the ration of cows receiving mineral acid silage did not produce alkalosis.

**The development of calves in the Tropics**, G. G. CARNEIRO and A. O. RHOD (*Trop. Agr.* [Trinidad], 13 (1936), No. 7, pp. 177-180, figs. 2).—The results obtained from two Brazil experiment station dairy herds on the growth rates of normally fed calves, including purebred Holstein, purebred Brown Swiss, and crossbred Holstein-zebu, are reported. Comparing the growth rates of these calves with the Eckles normal for purebred Holsteins, it is shown that all the purebred calves made approximately normal growth up to 4 mo. of age. Beyond this point the rate of growth is retarded, this condition being particularly noticeable beyond 6 mo. of age. A study of the feed consumption records leads to the conclusion that environmental factors other than nutrition are responsible for this subnormal development. The crossbred calves reared under identical conditions developed normally.

**[Dairying experiments in New York]** (*New York State Sta. Rpt.* 1936, pp. 21-24).—Results are reported on factors affecting the quality of Limburger and similar types of cheeses, the control of abnormal municipal milk supplies, and the relation of udder infections to total production and chemical composition of the milk.

**The relation of amino nitrogen content to quality of cream and butter**, D. H. JACOBSEN (*South Dakota Sta. Bul.* 304 (1936), pp. 11).—The principal conclusions presented in this bulletin have been noted (*E. S. R.*, 75, p. 687).

**Accumulation of protein in the foam of skim milk**, P. F. SHARP, R. P. MYERS, and E. S. GUTHRIE (*Jour. Dairy Sci.*, 19 (1936), No. 10, pp. 655-662, fig. 1).—In this report from the [New York] Cornell Experiment Station it is shown that in running skim milk through a separator as many as 16 times and removing the foam each time did not decrease its foaming capacity at temperatures ranging from 5° to 50° C. The protein content of the foam exceeded that of the skim milk from which it was obtained by 0.12 to 0.68 percent, and the increase in total solids in the foam was almost quantitatively accounted for by this accumulation of protein. The relative amounts of the major protein fractions in the skim milk did not change during repeated foaming.

In similar trials with whole milk no decrease in foaming quality was noted until partial churning occurred. Normal buttermilk foamed very little, while samples of the buttermilk extracted with petroleum ether foamed readily.

The decline in foaming ability of whole milk and the failure of buttermilk to foam is attributed to the presence of foam-breaking substances released by the fat globule rather than to the lack of foam-forming materials.

**The phospholipids in milk.**—IV, **Their chemical nature and their distribution among some milk products**, G. E. HOLM, P. A. WRIGHT, and E. F. DEYSHER (*Jour. Dairy Sci.*, 19 (1936), No. 10, pp. 631-639).—Continuing this line of investigation (E. S. R., 71, p. 238), this phase deals with the chemical nature of the phospholipids of milk. The approximate solubilities of the phospholipid fractions are given, and the relation of these solubilities to certain analytical methods is discussed. The composite molecular weight has been tentatively established as 775.76, on which basis the factor for conversion of phosphorus into milk phospholipids would be 25. The results indicate the distribution of the phospholipids in certain milk products to be as follows: Whole milk 0.0337 percent, skim milk 0.0169, 41-percent cream 0.1816, butter 0.1819, and buttermilk 0.1872 percent.

**The influence of method of sterilizing equipment upon development of oxidized flavor in milk**, A. C. DAHLBERG and D. C. CARPENTER (*Jour. Dairy Sci.*, 19 (1936), No. 8, pp. 541-551).—This study at the New York State Experiment Station was conducted with mixed herd milk produced under strict sanitary conditions and exposed only to aluminum utensils prior to time of pasteurization was used. Samples of raw milk and of different fractions of pasteurized milk collected off the cooler were scored for flavor at 1 hr. and 1, 2, and 3 days of age, and iron and copper determinations were made on each sample.

In all cases raw milk showed a satisfactory flavor at each stage of the test. In the case of hot water sterilization or chlorine sterilization followed by hot water rinse all milk, with the exception of the first 50 lb. coming off the cooler, maintained a satisfactory flavor over the 3-day period. The first 25 lb. of milk cooled in each case developed an oxidized flavor within 1 day, and the second 25-lb. fraction developed such flavors within 3 days. In the case of chlorine sterilization, the first 25 lb. of milk over the cooler had a pronounced coal tar flavor, and later fractions showed a much stronger tendency toward oxidized flavor than in the above trials, practically all samples developing this flavor within the 3-day period.

The solution of metals was not affected by the method of sterilization. In each case the first 25 lb. of milk discharged from the cooler showed a pronounced increase in both copper and iron, but later fractions showed only a slight increase over the raw sample. The raw sample averaged 0.131 and 0.379 p. p. m. of copper and iron, respectively, while the average of the pasteurized samples after discarding the first milk through the lines averaged 0.186 and 0.401 p. p. m. of copper and iron, respectively. The fact that the milk from chlorine-sterilized equipment was more susceptible to oxidized flavor indicates that the iron and copper contents of the milk are not the only factors involved in the development of this defect.

**Quality control of market milk**, N. E. LAZARUS (*Milwaukee, Wis.: Olson Pub. Co.*, [1935], pp. VIII+[1]+190, [figs. 44]).—A manual for rapid classification and detection of organisms affecting the quality of milk and its products, with suggestions as to their source, action, and control.

**Bacteria in relation to the milk supply: A practical guide for the commercial bacteriologist**, C. H. CHALMERS (*London: Edward Arnold & Co.*, 1935, pp. XII+192, pls. 4, figs. 31).—A treatise dealing with the principles and practical application of laboratory methods for bacterial control of milk supplies.

**Further studies of the composition of media for the bacteriological analysis of milk**, C. S. BOWERS and G. J. HUCKER (*Amer. Jour. Pub. Health*, 26 (1936), No. 4, pp. 350-352).—In general the results obtained in this study confirm earlier

findings by the authors (E. S. R., 73, p. 837), tryptone-glucose agar and tryptone-glucose skim milk agar proving more efficient in the bacteriological analysis of milk than standard peptone agar or standard agar supplemented with glucose and skim milk.

**Effect of temperature of incubation upon agar plate count of milk,** C. S. PEDERSON and M. W. YALE (*Amer. Jour. Pub. Health*, 24 (1934), No. 5, pp. 477-484, figs. 6).—In a study at the New York State Experiment Station, 78 samples of dairy products, including pasteurized milk, raw milk, cream, and ice cream, were plated on standard agar plates, and duplicates were incubated at nine different temperatures ranging from 21° to 55° C. for 48 hr. In all products tested maximum counts were obtained at about 32°, with counts at 37° ranging from 50 to 70 percent as high as the 32° counts in most cases. Slight temperature variations around 32° gave much smaller errors in counts than around 37°. The percentage of maximum count obtained in 48 hr. is much more constant at 32° than at 37°. Apparently counts obtained at 32° serve as a better means of comparing the quality of different samples, and this temperature is recommended to replace the present standard.

**Optimum temperature of incubation for standard methods of milk analysis as influenced by the medium,** M. W. YALE and C. S. PEDERSON (*Amer. Jour. Pub. Health*, 26 (1936), No. 4, pp. 344-349, figs. 3).—In a study at the New York State Experiment Station, 33 samples of raw and pasteurized milk were plated on tryptone-glucose skim milk agar and incubated at 11 different temperatures ranging from 18° to 55° C. During a 48-hr. incubation period the maximum number of colonies developed at slightly below 30° and slightly above 31° for the raw and pasteurized samples, respectively. These results correspond quite closely to those previously obtained when using standard peptone agar medium. It appears that (1) an incubation temperature of 32° or slightly lower is equally well adapted to either medium since it yields at least 95 percent on the average of the maximum 2-day count, (2) it is at the top of the curve where slight temperatures cause the least error, and (3) the percentage of the maximum 48-hr. count does not vary greatly between samples. On the other hand, an incubation temperature of 37° was equally undesirable for either medium, since it yields only about 50 percent on the average of the maximum 2-day count and since it is in the steepest part of the descending curve so that variations in incubation temperature result in relatively large errors.

**Evaluation of certain media for the detection of colon organisms in milk,** C. N. STARK and L. R. CURTIS (*Amer. Jour. Pub. Health*, 26 (1936), No. 4, pp. 354-356).—The [New York] Cornell Experiment Station has studied the suitability of six media for the detection of colon organisms in milk with special reference to the ability of the medium to inhibit the growth of bacteria often responsible for false tests. It is concluded that crystal violet, Dominick-Lauter, and gentian violet broths are not satisfactory for this purpose since each in the presence of milk is relatively unselective in the type of bacterial growth sustained. Brilliant green bile broth is more selective, and its effectiveness is greatly improved by adding 0.5 percent sodium formate. Formate ricinoleate is considered entirely satisfactory in the detection of the colon group, inhibiting the growth of all false test organisms.

**Attainable standards in the bacterial counts of raw and pasteurized milk,** M. E. BARNES (*Amer. Jour. Pub. Health*, 26 (1936), No. 6, pp. 561-566, figs. 2).—This paper is based on a study of the raw milk supply of an Iowa State hospital extending over 43 mo. Following a period of cooperation with milk producers, during which time they were instructed in sanitary precautions necessary for clean milk production and in which the physical equipment of

the dairies was put in satisfactory condition, the raw milk delivered to the plant had an arithmetical average bacterial count of 1,600 per cubic centimeter, with a range of from 100 to 19,000.

It is suggested that 2,000 bacteria per cubic centimeter may be considered as the upper limit of an ideal zone within which mastitis and environmental factors are reduced to a minimum, while counts above this level indicate that either one or both of these factors are operative. The results obtained indicate that a logarithmic monthly average count of 5,000 bacteria per cubic centimeter in raw milk is within the possibility of attainment without necessitating an elaborate outlay of equipment in the dairy. Similar studies with the pasteurized milk supply led to the adoption of a maximum count of 1,000 per cubic centimeter as the criterion of excellence.

**Classification of the organisms important in dairy products.**—I, *Streptococcus liquefaciens*, H. F. LONG and B. W. HAMMER (*Iowa Sta. Res. Bul.* 206 (1936), pp. 217–251).—Employing the method described for the isolation of acid-proteolytic streptococci from dairy products, 65 such cultures from cheese, 23 from milk and cream, and 3 from butter were isolated, and these, along with 10 cultures obtained from other laboratories, have been extensively studied.

These 101 cultures were all identified as *S. liquefaciens*, and the different characters of each were found to be identical except for the rapidity of reduction of litmus milk and the fermentation of sucrose. These organisms coagulated milk by enzyme action rather than by the formation of acid, the titratable acidity at the time of coagulation averaging 0.27 percent and the pH 5.9. All cultures produced volatile acids, carbon dioxide, and acetylmethylcarbinol in milk, although the amounts produced by various cultures under uniform conditions varied widely. The rate of production was generally lower at the incubation temperature of 37° C. than at 21°. When incubated for 7 days at 21°, additions of either citric acid or acetaldehyde to skim milk cultures generally reduced the production of volatile acids and increased the yield of acetylmethylcarbinol. In five cases studied acetylmethylcarbinol was not oxidized to diacetyl nor reduced to 2,3-butylene glycol, indicating that the former is an end product. None of the cultures hydrolyzed butterfat or cottonseed oil, hence the species is considered nonlipolytic. Four cultures studied greatly increased the soluble nitrogen in milk, and proteolysis was largely complete after a short incubation period. The distribution of soluble nitrogen into the various fractions was similar in all cultures and at incubation temperatures of either 37° or 21°. The cultures remained viable at 5° over a long period. In six cultures studied heat resistance varied considerably with age. These cultures were all killed in 40 min. at 65.6°.

**The action of aldehydes on certain cultures of *Streptococcus liquefaciens* in milk.** B. W. HAMMER (*Jour. Bact.*, 31 (1936), No. 5, pp. 479–487).—In studies at the Iowa Experiment Station the production of acetylmethylcarbinol due to the action of certain cultures of *S. liquefaciens* in milk was greatly increased by the addition of rather small amounts of acetaldehyde.

Trials in which propionaldehyde, n-butyraldehyde, or n-valeraldehyde were added to milk containing these organisms showed an increase in the yield of acetylmethylcarbinol of the same order as that obtained by adding acetaldehyde, but little or no response resulted from adding formaldehyde or furfuraldehyde. Only in the trials with the n-valeraldehyde was there an indication of the formation of small amounts of a higher homologue of diacetyl.

**The prevalence and classification of hemolytic streptococci in pasteurized milk.** L. W. SLANETZ (*Jour. Bact.*, 32 (1936), No. 1, p. 127).—This brief report from the University of New Hampshire indicates that samples of pasteurized

milk showing counts of less than 10,000 by standard plate method sometimes contain as many as 50,000 hemolytic streptococci per cubic centimeter. Meat extract agar containing 1 percent proteose peptone and 5 percent sheep's blood was satisfactory for the detection and isolation of these bacteria. A detailed study of 20 such cultures showed them to be very heat-resistant, some strains withstanding a temperature of 70° C. for 30 min. On staining they appeared as long-chained streptococci, usually of the so-called alpha-prime type.

**Sugar- and lactate-fermenting butyric acid bacteria** [trans. title], J. VAN BEYNUM and J. W. PETTE (*Zentbl. Bakt. [etc.]*, 2. Abt., 93 (1935), No. 9-12, pp. 198-212).—In a study of butyric acid bacteria encountered in cheese making, cultures were isolated from milk by the Weinzierl test (E. S. R., 45, p. 73), using a culture medium of autolyzed yeast plus 1.5 percent of sodium lactate. Of those strains which did not liquefy gelatin it is shown that some have the ability to ferment lactose and others to ferment lactate, and in either case those fermenting one could not ferment the other. The lactose-fermenting group is not likely to prove detrimental in cheese manufacture. It is suggested that this group retain the name *Clostridium saccharobutyricum* (including *C. butyricum*). The lactate-fermenting group actively ferments glucose and levulose and sometimes galactose and arabinose, and is primarily the cause of gassy butyric acid fermentation in cheese. The authors have proposed the name *C. tyrobutyricum* for this group. By enriching milk bacteria in glucose medium and inoculating into a yeast autolysate plus lactate medium and into peptone solution plus mannite, it is possible to determine the presence of these two types of organisms since only *C. tyrobutyricum* will grow on the former and *C. saccharobutyricum* on the latter.

**Butyric acid fermentation and lactic acid fermentation in silage** [trans. title], J. VAN BEYNUM and J. W. PETTE (*Zentbl. Bakt. [etc.]*, 2. Abt., 94 (1936), No. 19-23, pp. 413-433).—Continuing this line of investigation (E. S. R., 76, p. 389), an explanation is sought for the fact that, although evidence of butyric acid fermentation is found in practically all lots of mineral acid silage, even those having a pH below 3, only silage having a pH above 3.5 has generally proved to be detrimental in cheese manufacture. It is suggested that since lactic acid fermentation occurs only at a pH above 3.5 it is theoretically possible to have two types of silage, namely, with and without lactic acid fermentation. The study noted above is referred to as indicating that rapid and uniform acidulation of silage to prevent lactic acid fermentation would eliminate the second type of butyric acid organism and render the silage harmless from this standpoint.

**Effect of salts on the solubility of casein and paracasein**, P. F. SHARP and T. J. MCINERNEY (*Jour. Dairy Sci.*, 19 (1936), No. 8, pp. 573-579, figs. 2).—This contribution from the [New York] Cornell Experiment Station gives the results of a study of the solubility of grain curd casein and other acid caseins and of paracasein (commercial rennet casein) at different pH levels and in the presence of 0.1 N and 0.5 N solutions of sodium chloride, sodium fluoride, and sodium iodide.

It is shown that the pH precipitation zone of paracasein is much wider than that of casein. Casein was completely soluble at a pH of 7 or above, and the presence of either the fluoride, chloride, or iodide increased the alkaline solubility zone, the iodide exerting the most pronounced effect in this respect. Paracasein showed marked insolubility at from pH 4.5 to 7, and the presence of either the chloride or iodide restricted the alkaline solubility zone. Sodium fluoride showed an anomalous behavior in that its presence caused a gradual increase in paracasein solubility as the pH increased from 5 to 10 which is

associated with precipitation of the calcium. The concentrations of sodium chloride and sodium iodide used markedly increased solubility of paracasein at a pH zone around 6, and it is shown that in the presence of a suitable concentration of sodium chloride paracasein has solubility zones at pH 2.5, 6, and 9.5, and zones of insolubility at 1, 4.5, and 7 to 9. The favorable effect of the peptizing action of sodium chloride on paracasein at a pH of 5.5 to 6 on the texture of Cheddar cheese is pointed out. Based on results of this study and other closely related studies, certain factors influencing the body and texture of processed cheese are discussed.

**Paraffin waxing of baby Gouda cheeses.** C. VAANDRAGER (*Farming in So. Africa*, 11 (1936), No. 124, pp. 293, 294, fig. 1).—In comparing the loss of moisture in baby Gouda cheeses (approximately 1 lb. each) when untreated, when dipped in pure paraffin wax, and when dipped in a special paraffin wax (melting point from 125° to 130° F.), it was shown that the loss in weight over a 28-day storage period amounted to 10.9, 2.49, and 0.69 percent, respectively. The pure paraffin proved unsatisfactory because the coating was very brittle and subject to cracking and blistering when handled. Waxing baby Gouda cheeses is considered essential because of the resulting decrease in loss of moisture, the prevention of tough rind formation, and the prevention of surface mold growth.

**The bacteriology of Swiss cheese.**—V, The use of *Streptococcus thermophilus* in ripening milk for Swiss cheese, W. C. FRAZIER, H. F. LONG, and W. T. JOHNSON, JR. (*Jour. Dairy Sci.*, 19 (1936), No. 8, pp. 535-539).—This line of investigation (E. S. R., 74, p. 844) has been continued.

Ripening milk by inoculating with *S. thermophilus* (strain C<sub>2</sub>) and holding at from 20° to 25° C. overnight gave unsatisfactory results, producing No. 2 cheese of lower grade than the control. Similar results were obtained from the use of *S. lactis* in the same manner, while the addition of this organism to the first milk in the kettle also gave unsatisfactory results. Most satisfactory ripening was obtained by inoculating the milk with *S. thermophilus* and holding it at 50° for from 30 to 60 min. Ripening periods of more than 60 min. generally resulted in a lowering of the grade. The beneficial effects of ripening with this organism is dependent on the ripeness of milk prior to inoculation as indicated by methylene blue reduction time. In general milk having a reduction time of less than 5 hr. is not benefited by this practice. Ripening part of the cheese milk with *S. thermophilus* may be of aid when the kettle milk acts "dead" or when the curd does not have the proper consistency in the kettle.

**Studies on the emulsifying salts used in processed cheese.** H. L. TEMPLETON and H. H. SOMMER (*Jour. Dairy Sci.*, 19 (1936), No. 8, pp. 561-572, figs. 6).—This contribution from the Wisconsin Experiment Station presents a comparison of sodium citrate, potassium citrate, tetrasodium pyrophosphate, sodium metaphosphate, and a fusion mixture of equal parts of the mono- and disodium salts of orthophosphoric acid as emulsifying salts in the preparation of processed cheese. The salts were used separately in amounts ranging from 1 to 5 percent (1 to 3 percent for potassium citrate). Data are presented for the various concentrations of each salt used in relation to total moisture of the cheese, percentage loss of moisture during 11 months' storage, pH value, titratable acidity, body, degree of fat leakage, total ash, total nitrogen, water-soluble nitrogen, 5 percent of sodium chloride soluble nitrogen, and the sum of the water-soluble and sodium chloride soluble nitrogen fractions.

Properties of the cheese as judged by sight, taste, and smell indicated that all samples containing sodium citrate were satisfactory. Potassium citrate imparted a bitter taste which increased during storage. Two percent of pyrophos-

phate was satisfactory, but higher concentrations gave a bitter flavor and also tended to crystallize out in white lumps. The metaphosphate imparted a sour taste likely to be considered objectionable. Both of these salts have limited solubility, and moreover they produced a cheese of very firm body resistant to melting. It is concluded that none of the emulsifiers used were superior to sodium citrate, and it is doubtful if any are equal to it if all points are considered.

**The use of sugar in making good quality ice cream,** P. S. LUCAS (*Ice Cream Trade Jour.*, 32 (1936), No. 4, pp. 34, 35).—This article from the Michigan Experiment Station presents brief data on the effect of various concentrations of sugar in the ice cream mix on specific gravity, freezing point, time required to secure maximum overrun, and the maximum overrun obtainable. The suitability of various kinds of sugars for ice cream manufacture is briefly discussed.

**Using corn sugar as an ingredient in the manufacture of ice cream,** P. H. TRACY (*Ice Cream Trade Jour.*, 32 (1936), No. 2, p. 30).—The Illinois Experiment Station briefly notes that corn sugar is less sweet than cane sugar, determined as of the order of 65 to 70 compared with cane sugar at 100. The use of 25 percent of corn sugar in the total sugar produced a smoother textured product of somewhat softer body. It lowered the freezing point, necessitating a somewhat lower freezing and also a lower dipping temperature. On the basis of consumer preference little difference was noted either as to flavor, body, or sweetness of ice creams containing 25 percent of corn sugar or all cane sugar.

**The use of stabilizing agents in manufacturing ice cream,** P. H. TRACY (*Ice Cream Trade Jour.*, 32 (1936), No. 3, pp. 31, 32).—This article from the Illinois Experiment Station briefly reports the results of investigations dealing with the comparative merits of gelatin, sodium alginate, Hygell (a carob bean product), and fruit pectin as stabilizing agents in the manufacture of ice cream.

**Are flavor and coloring sources of bacteria in ice cream?** P. H. TRACY and M. J. PRUCHA (*Ice Cream Trade Jour.*, 32 (1936), No. 1, pp. 17, 18, 20).—In this brief report of a study in progress at the Illinois Experiment Station the results secured indicate that such materials as fruits, nuts, candies, and other flavoring and coloring materials are frequently heavily infested with bacteria, and that under such conditions they may be considered a factor affecting the total number of bacteria in the finished ice cream. *B[acillus] coli* was found in more than 10 percent of all such samples tested, indicating unsanitary conditions in the preparation of these products. The possibility of correcting this condition by proper sanitary regulations is discussed.

## VETERINARY MEDICINE

[Work in animal pathology and parasitology by the Bureau of Animal Industry] (*U. S. Dept. Agr., Bur. Anim. Indus. Rpt.*, 1936, pp. 4-6, 20-23, 23-26, 39-60).—The work of the year (*E. S. R.*, 74, p. 693) dealt with the detection and control of Bang's disease; vesicular exanthema of swine; vesicular stomatitis; hog cholera and its control; the use of tuberculin, mallein, and abortin and stained diagnostic antigens; the eradication of scabies and anthrax; diagnosis and control of glanders, dourine, trypanosomiasis, and rabies; the streptococci involved in bovine mastitis; the transmission of infectious equine encephalomyelitis; investigations of equine infectious anemia; a dermatomycosis in guinea pigs; an unusual case of *Brucella suis* infection of swine; cultures of *Erysipelothrix rhusiopathiae*; a finding of the identity of the American and Australian laryngotracheitis virus; chickens with bumblefoot; an unusual form of fowl cholera; the treatment of hemorrhagic septicemia with soda; the applicability

of complement fixation in the diagnosis of anaplasmosis; stock-poisoning plants; tick eradication; tuberculosis in bovines, sheep, poultry, and swine; parasites of horses, ruminants, swine, poultry, and other animals; and treatment for internal and external parasites.

[**Work with diseases and parasites of livestock**], C. U. DUCKWORTH (*Calif. Dept. Agr. Bul.*, 24 (1935), No. 4, pp. 364-375).—This is the annual report dealing with the occurrence of and control work with infectious diseases and parasites of livestock in California in 1935 (E. S. R., 74, p. 253).

[**Report of work in animal pathology, bacteriology, and parasitology by the Michigan Station**] (*Michigan Sta. [Bien.] Rpt.* 1935-36, pp. 9-12, 13, 14, 15, 16, 16-20).—The work of the biennium reported upon (E. S. R., 73, p. 536) includes control and eradication of Bang's disease, nonspecific abortions, calf pneumonia, agglutination testing, streptococcal mastitis, sheep diseases, bacteriology of eating and drinking utensils, disinfection of poultry houses by means of fire guns, control of tapeworms, the effect of hardware cloth floors on the incidence of coccidiosis of domesticated animals, ameba studies, diagnosis of helminth infestations in living animals with special reference to diagnosis arrived at through fecal examinations, vaccinal immunization of cattle against Bang's abortion disease, the chemistry of *Brucella* cells, nonspecific agglutination in the *Brucella* group, and undulant fever.

[**Report of work in animal pathology by the Missouri Station**] (*Missouri Sta. Bul.* 370 (1936), pp. 81-85, 91, 92).—The work of the year referred to (E. S. R., 75, p. 102) includes low titer reactions to the Bang agglutination test in cattle, transmission of the Bang abortion infection of swine to cattle, and the significance of low agglutination reactions in unbred gilts, all by C. Elder; avitaminosis A in swine, by Elder and L. A. Weaver; toxemia in sheep, by Elder and A. W. Uren; the tube agglutination test compared with the rapid or plate tests on low reacting serums, by Elder and P. L. Piercy; fowl paralysis or neuritis of fowls, leucosis in fowls, blackhead in turkeys, pullorum disease testing in fowls, fowl pox vaccine distribution, and rabies diagnostic service, all by A. J. Durant and H. C. McDougle; Bang's disease testing and horse bot control campaign, both by Piercy; and diagnostic service on poultry diseases, by Durant, McDougle, and Uren.

Some diseases of farm animals ([*Gt. Brit. Min. Agr. and Fisheries Bul.* 1, 7, ed. (1936), pp. VI+151, [pls. 5], [figs. 10]).—A seventh edition of this practical account (E. S. R., 74, p. 391).

**Report of the director of veterinary research for the year 1935**, D. A. LAWRENCE (*South. Rhodesia, Dir. Vet. Res. Rpt.*, 1935, pp. 9).—The results of work with laboratory products and service, research, and work with infectious and parasitic diseases are reported upon.

**The phenol coefficient as a measure of the practical value of disinfectants**, J. C. VARLEY and G. F. REDDISH (*Jour. Bact.*, 32 (1936), No. 2, pp. 215-225).—The work reported upon has shown that "when coal tar disinfectants and cresylic acid disinfectants are diluted to 20 times their phenol coefficient, they are effective in killing representative pathogenic micro-organisms under practical conditions of use. It is further shown that disinfectants of varying strengths, that is, whether they have a high or low phenol coefficient, have the same germicidal activity and are equally effective under practical conditions when diluted to 20 times their respective phenol coefficients.

"As a result of these tests it is concluded that (1) the phenol coefficient figure is a suitable measure of the practical value of phenollike disinfectants when the factor '20 times the phenol coefficient' is employed for calculating the dilutions for use in practice. (2) Disinfectant solutions made up to 20

times their phenol coefficient are of sufficient strength to kill very large numbers of disease-producing micro-organisms under practical conditions. (3) When dilutions for use are made on this basis, coal tar disinfectants and cresylic disinfectants should be equally germicidal. (4) When phenollike disinfectants are diluted in this way they should be as effective in killing disease-producing micro-organisms under practical conditions as is 5 percent carbolic acid."

**Stimulation of healing in non-healing wounds by allantoin occurring in maggot secretions and of wide biological distribution, W. ROBINSON** (*Jour. Bone and Joint Surg.*, 17 (1935), No. 2, pp. 267-271).—In reporting upon maggot therapy (E. S. R., 74, p. 256; 76, p. 246) the author presents a preliminary account of work with allantoin, a constituent of the urinary secretions of surgical maggots and of common occurrence in plants and animals, the therapeutic value of which was first called to attention by Macalister (E. S. R., 26, p. 580).

The treatment of hospital cases in Washington and New York has shown that allantoin stimulates healing, with abundant growth of healthy granulation tissue in slowly healing suppurative wounds. The excretion of this substance into the wound is considered to be one of the factors contributing to the remarkable healing effects obtained in maggot therapy, although the claim is not made that it can be substituted for maggots. It is pointed out that allantoin, which is bland, stable, and harmless, has no odor, and is nonstaining, can be obtained commercially, and that the treatment is simple, painless, and inexpensive.

The account is accompanied by a list of 11 references to the literature.

**Use of urea to stimulate healing in chronic purulent wounds, W. ROBINSON** (*Amer. Jour. Surg.*, n. ser., 33 (1936), No. 2, pp. 192-197).—In continuation of the work above noted, the author reports having found urea as well as allantoin to stimulate healing in chronic purulent wounds. Fourteen typical case histories supplied by medical cooperators are briefly presented with a view to bringing the use of this simple, harmless, and effective treatment to the attention of those who have cases of chronic external suppurating wounds.

The application of a 2-percent solution results in the cleansing of such wounds by the removal of necrotic material and pyogenic bacteria present and a promotion of the growth of granulation tissue. Like allantoin, urea occurs in maggot excretions and its presence serves as a further elucidation of the remarkable efficiency of surgical maggots in healing chronic suppurating wounds.

"Urea, which is manufactured in enormous quantities for use as a soil fertilizer, is available for therapeutic use without any connection with animal excretions. It can be made from three simple gases, nitrogen, hydrogen, and carbon dioxide, and is a pure white crystalline substance. In wound treatment a 2-percent solution in water has been used on saturated gauze dressings applied directly to the wound. The solution is bland, odorless, and nontoxic. The treatment is very inexpensive and easily given.

"Urea is present in the cells of all the tissues of the body; it rapidly permeates the membranes of the cells and its concentration therein rises and falls readily with that of the blood and lymph. In view of the remarkable cleansing and healing properties of urea in chronic purulent wounds, it appears that the general conception of this material as only a waste product has tended to obscure its therapeutic character."

**Buffered blood cultures, C. I. NELSON** (*Jour. Bact.*, 32 (1936), No. 1, p. 121).—The author has found the use of a buffer solution (McIlvaine's) composed of 1.83 cc of a 0.1 M citric acid solution combined with 18.17 cc of a 0.2 M

disodium phosphate and having a reaction of pH 7.4 to provide a medium for the culture of organisms in blood. Three to 5 cc of blood drawn aseptically into 10 cc of buffer solution lacks the inhibiting effect which often makes blood culturing ineffective. The blood does not clot. The blood serum constituents serve as nutrients.

"Cultures have easily been obtained of various streptococci, *Brucella abortus*, *Eberthella typhosa*, and other organisms associated with fever, as well as others of indeterminate function."

**"Vitamin G" in coccidian infection**, E. R. BECKER and N. F. MOREHOUSE (*Jour. Bact.*, 32 (1936), No. 1, pp. 121, 122).—The authors have found that "the intestinal location and life cycle of *Coccidia* make oocyst counts an index to their multiplication. Quantitative data were based on counts by the dilution method subsequent to infection with uniform numbers of oocysts in reference and test series. The host was the rat; the parasite, *Eimeria mitairii*; the reference diet, a basal plus 10 percent powdered yeast. Oocyst counts from hosts on a ration deficient in vitamins B and G were about a fifth of the normals; from G-deficient hosts, a third of normal; B-deficient hosts, equal to normal. Liver extract equivalent to 4 g as a daily supplement to basal diet conditioned counts a third to fourth of normal; 2 percent powdered liver and 2.5 percent rice polish counts a seventh of normal; 10 percent powdered liver and 4 percent rice polish counts a third of normal. Only the last ration gave host growth equal to normal or reference series. Powdered skim milk as the sole source of vitamins B and G gave slight growth, but parasite counts were only a small fraction of normal. Liver and skim milk are either deficient in a coccidium accelerant or restrain their numerical increase by positive means."

**The indol tolerance of certain strains of the colon-aerogenes group**, R. L. FRANCE (*Jour. Bact.*, 32 (1936), No. 2, pp. 211-214).—Contributing from the Massachusetts Experiment Station, the author reports upon a study of the indol tolerance of 173 strains of fecal type *Escherichia coli*, 155 strains of *Acrobacter aerogenes*, and 83 strains of "intermediates." The results indicate that these members are so similar in their tolerance for indol that no practical application can be made.

**The fermentation reactions of *Erysipelothrix rhusiopathiae***, A. W. DEEM and C. L. WILLIAMS (*Jour. Bact.*, 32 (1936), No. 3, pp. 303-306).—In the work with swine erysipelas reported, 37 strains of *E. rhusiopathiae* were used to determine the fermentation reactions of the species. Eleven of the strains originated in the United States, the others having been secured from European laboratories. A special sugar-free broth was prepared in which the organisms were grown readily. Only glucose, fructose, galactose, and lactose were fermented by all 37 strains. A slight acid reaction was detected in the cultures of some strains containing mannose, arabinose, and xylose. None of the other carbohydrates tested were fermented.

"No correlation was apparent between the source of the strains and their fermentation reactions. The uniformity of results demonstrates not only the biochemical activity of this bacterium, but also the reliability of sugar fermentation tests for the identification of this species and its differentiation from organisms of the *Corynebacterium* group with which it may be confused."

**Specificity of the dye in the crystal-violet agar reaction of staphylococci**, G. H. CHAPMAN (*Jour. Bact.*, 32 (1936), No. 2, pp. 199-205).—Heavy inoculation was found necessary to secure growth of staphylococci on crystal violet agar. Solutions of crystal violet used for the preparation of crystal violet agar should be freshly prepared. The optimum dilution is between 1:300,000 and 1:350,000. Although representatives of the different groups of biological dyes were tested

with staphylococci, color changes similar to those produced on crystal violet media were obtained only with media prepared from dyes containing methyl, gentian, or crystal violet. It is concluded that the violet agar reaction of staphylococci is highly specific as far as the dye is concerned, and depends upon a reaction of growth products of staphylococci with either pentamethyl pararosaniline or hexamethyl pararosaniline.

**Observations on the serology of streptococci of bovine origin, S. E. HARTSELL and W. N. PLASTRIDGE** (*Jour. Bact.*, 32 (1936), No. 1, pp. 126, 127).—One hundred and twenty cultures that had been identified by the biochemical test as either *Streptococcus mastitidis* group A (Lancefield's group B) or group B or saprophytes were examined by the slide agglutination test and the precipitin test of Lancefield (*E. S. R.*, 69, p. 581).

"In general, the three biochemical types were serologically distinct. Of 70 group A strains, 65 which were associated with other evidence of mastitis were divided into three serological types. Five group A cultures which failed to react with the three type serums were from samples from mastitis-free quarters. Of 23 group B cultures, 15 reacted with one of three types of group B antiserum. Of 17 cultures classed as saprophytes by biochemical tests, 11 reacted with one of three types of antiserum against saprophytic organisms, and 6 failed to react with any serum. Ten cultures which reduced methylene blue milk (1:5,000), but otherwise resembled group A biochemically, were associated with other evidence of mastitis; they reacted with group A antisera. Members of group A which fermented salicin were identical serologically with those which failed to do so. Strongly hemolytic sorbitol-fermenting cultures which reacted with our group A antisera were observed in one instance."

**Source of the organisms associated with sub-clinical mastitis** (*New York State Sta. Rpt. 1936*, pp. 24, 25).—The work of the year (*E. S. R.*, 74, p. 853) is briefly referred to.

**A preliminary note of the life history of *Schistosoma turkestanicum* Skrjabin 1913, C. MACHATTIE** (*Vet. Jour.*, 32 (1936), No. 8, pp. 291-299, pls. 4).—*S. turkestanicum* was found to be "a formidable and dangerous parasite of domestic animals in the Marsh-Arab and rice field areas of Iraq. In addition to cattle, sheep, goats, and water buffaloes, it has been proved that camels, horses, donkeys, and mules are also hosts. The arrest of the egg in the intestinal mucosa and the consequent formation of nodules largely destroys the value of the intestine as a commercial product. Man and domestic and wild birds are apparently immune to infection despite continuous exposure to the attacks of the cercariae of *S. turkestanicum*. The snail host of *S. turkestanicum* is *Limnea tenera euphratica* Mousson ('phase' *Angustior* Mousson). Cercariae of *S. turkestanicum* become very sluggish toward the end of the hot season (late September) and disappear from October to May. It seems probable that livestock can then drink from infected ponds with comparative impunity."

**The spread of tularemia through water, as a new factor in its epidemiology, S. P. KARPOFF and N. I. ANTONOFF** (*Jour. Bact.*, 32 (1936), No. 3, pp. 243-258).—Observations conducted by the epidemiological section of the Institute of Epidemiology and Microbiology at Tomsk, Siberia, of the spread of tularemia through water are reported upon.

It is pointed out that while in the United States the wild rabbit is the principal source of tularemic infection in man, the water rat is the principal source in the Union of Soviet Socialist Republics. Other hosts of the infection are listed. The spread of the infection by water was proved experimentally and bacteriologically. "The quantity of micro-organisms in the infected water courses may sometimes be so considerable that their isolation

does not meet with great difficulties. In our experiments 100 percent of the guinea pigs infected with the water died and their organs showed characteristic pathological-anatomical changes. From the organs of all these guinea pigs by water we obtained cultures of *B[acterium] tularensae*."

**Results of administering two calfhooed injections of a living *Brucella abortus* culture to prevent Bang's disease, A. L. DELEZ** (*Jour. Amer. Vet. Med. Assoc.*, 90 (1937), No. 1, pp. 61-65).—In summarizing the results of work at the Indiana Experiment Station, conducted in an attempt to increase their resistance, the author reports that eight heifer calves that had received two subcutaneous calfhooed injections of a living *B. abortus* culture dropped living calves. "Two calves died shortly following delivery. *B. abortus* infection was recovered from five heifers. Serum agglutination titers subsequent to the administration of two injections were higher than when only one injection was given. The titers dropped considerably 4 mo. following the second injection. A study of the opsonocytaphagic activity of the blood following parturition revealed only a slight degree of phagocytosis in most cases."

**Oat hay poisoning, I. E. NEWSOM, E. N. STOUT, F. THORP, JR., C. W. BARBER, and A. H. GROTH** (*Jour. Amer. Vet. Med. Assoc.*, 90 (1937), No. 1, pp. 66-75).—Several serious losses of cattle feeding on oat hay are described in this contribution from the Colorado Experiment Station. The symptoms were suggestive of poisoning by hydrocyanic acid, but no cyanide had been found in the hay except in cane, which in most of the outbreaks was not even under suspicion. Pigweed, while almost always a contaminant of oat hay, produced no symptoms in sheep, rabbits, or guinea pigs when fed experimentally. "By feeding the original hay the disease was apparently reproduced in five of the steers, causing death in three. Two of the three showed the presence of hydrocyanic acid in the rumen by means of the sodium picrate paper test some hours after death. No injurious substance could be shown to be present in the hay or any of its constituents when fed to sheep, rabbits, or guinea pigs. Watery, alcoholic, and ether extracts were harmless to laboratory animals."

**The pathogenesis of ketosis: Pregnancy disease of sheep, L. M. RODERICK, G. S. HARSHFIELD, and M. C. HAWN** (*Jour. Amer. Vet. Med. Assoc.*, 90 (1937), No. 1, pp. 41-49).—In continuing their studies at the North Dakota Experiment Station (E. S. R., 70, p. 833) the authors have found that the pregnancy disease problem is quite definitely related to carbohydrate metabolism. "With an inadequate carbohydrate intake, the glycogen is withdrawn from the liver to maintain the blood sugar level in metabolism and fat takes its place. While the increased excretory burden associated with pregnancy may provoke some liver injury, the fatty changes in the liver and kidney are readily produced by starvation and an inadequate nutritional intake. There are unpublished experimental data to show that the newborn lamb is provided with a reserve of glycogen in its liver. The fetal lamb liver is storing glycogen for some days prior to parturition, providing the ewe is adequately fed. As high as 9 percent of glycogen has been found in the livers of these lambs, which is two or three times as much as in the liver of the ewe. The demands of a twin pregnancy are thus apparent." The experimental work is considered to have demonstrated "the part that semistarvation and inadequate feed play in the causation of the disease. The nutrition of ewes should be such that their condition improves with advancing pregnancy. The animal body has a greater reserve of fat and protein than of carbohydrate. The use of a liberal and balanced ration is needed, yet the use of molasses to supplement roughages of low quality seems justified on fundamental principles."

**A disease of horses caused by feeding moldy corn**, L. H. SCHWARTE, H. E. BIESTER, and C. MURRAY (*Jour. Amer. Vet. Med. Assoc.*, 90 (1937), No. 1, pp. 76-85, figs. 7).—Studies of a disease of horses, involving especially the central nervous system and caused by the ingestion of moldy corn, are reported upon, the work having been supported in part by grants from the Iowa Experiment Station and the Rockefeller Fluid Research Fund.

"Three of the five horses experimentally fed moldy corn died, while two were destroyed, one of which was in a moribund condition and the other showed marked intoxication and severe incoordination. These subjects presented gross and histologic evidence in the brain and spinal cord distinguishable from the specific virus disease. Bacterial cultures made from the brain and other organs were negative. Intracerebral inoculations into guinea pigs were likewise unsuccessful. This condition is not associated with the specific virus encephalomyelitis.

"In Iowa, moldy corn poisoning occurs usually from November until May, during which time the virus disease has subsided. It is possible, however, to have an overlapping in the occurrence of these two diseases in October and November, depending upon the temperature and rainfall affecting the development of the corn. The specific virus encephalomyelitis of horses is seldom encountered after the first killing frosts. The perivascular cuffing and neuronophagy were never present in either field cases or those produced experimentally by feeding moldy corn. The moldy corn disease is always associated with necrosis, edema, advanced hemorrhagic lesions, and degenerative processes. The two diseases were clearly differentiated on histologic evidence alone.

"The term 'moldy corn poisoning' should be used provisionally to designate this disease until the organism or group of organisms which are responsible for this action on the corn are isolated and their ability to produce these toxins demonstrated. There are a number of organisms present in moldy corn. Some are recognized as plant pathogens and others are not. Close cooperation with plant mycologists is necessary to determine the factors involved. None of these organisms which are found on moldy corn invades the animal body beyond the digestive tract. The term 'cornstalk poisoning' is not well chosen, as there is considerable evidence to show that the toxic agent is present in the kernels and possibly in the cobs as well. Because of the varied clinical pictures seen as the result of moldy corn poisoning, we do not feel justified in differentiating it clinically from the virus disease. The clinical symptoms and course of the disease depend largely on the extent and the part of the central nervous system which is involved. The history of the case and the clinical manifestations, together with the gross and histologic changes, should make it possible to differentiate moldy corn poisoning from the specific virus encephalomyelitis in horses."

**Observations on canine babesiasis (piroplasmosis)**, D. A. SANDERS (*Jour. Amer. Vet. Med. Assoc.*, 90 (1937), No. 1, pp. 27-38, figs. 9).—Contributing from the Florida Experiment Station, the author reports upon a chronic form of babesiasis due to *Babesia canis* that has been encountered in various breeds of dogs in widely separated locations in Florida, in which State the first case was observed by P. Eaton<sup>1</sup> at Jacksonville in 1934. "The training and coursing activities of affected greyhounds are seriously interrupted. The brown dog tick, *Rhipicephalus sanguineus*, is suspected as being the principal vector of the infection. The presence of chronic canine babesiasis as encountered was

<sup>1</sup> *Jour. Parasitol.*, 20 (1934), No. 5, pp. 312, 313.

determined by blood inoculations and splenectomies of test animals. Young pups splenectomized during or shortly following clinical reactions usually succumb within [from] 24 to 48 hr. as a result of severe relapse associated with numerous *B. canis* in the blood. Pups in a state of relative immunity or premunized to *B. canis* did not react to intraperitoneal injections of blood from dogs showing symptoms of malignant jaundice, while nonimmune pups reacted to such injections showing *B. canis* in the blood."

**Types of fox encephalitis virus**, R. G. GREEN (*Jour. Bact.*, 32 (1936), No. 1, pp. 119, 120).—In groups of foxes passively immunized by a serum made from the fox encephalitis virus a mild type of the disease has been observed to develop showing a mortality of about 1 percent. Under experimental conditions this virus produces a mortality of only 20 percent, but with endothelial cell inclusions typical of encephalitis. Subsequent observations have indicated that this new type of virus is immunologically distinct from the type originally described. The original virulent virus is now referred to as type A; the newly recognized virus of low virulence is described as type B fox encephalitis virus.

**Purification of fox encephalitis virus by tryptic digestion**, R. G. GREEN (*Jour. Bact.*, 32 (1936), No. 1, p. 120).—In work with the fox encephalitis virus smears made from the ependyma of foxes inoculated by cisterna puncture were stained to show the presence of the intranuclear inclusions of fox encephalitis. "A suspension of ependymal scrapings containing inclusion bodies was digested by the use of trypsin and enterokinase. Definite clearing of the suspension was noted, and cellular material could not be demonstrated by stained smears after digestion. Upon centrifuging, a sediment was obtained which was resuspended in distilled water. Ten similar washings were performed, using 10 cc of liquid for each washing. Finally, suspended in saline solution, the sediment produced typical fox encephalitis when injected into foxes by cisterna puncture, although a low concentration of the virus was indicated. This procedure demonstrates the resistance of the virus to tryptic digestion and its occurrence under these conditions in fairly large masses capable of ordinary centrifugation."

**A six-point general sanitation program for poultry**, P. W. ALLEN (*Poultry Sci.*, 15 (1936), No. 5, pp. 414, 415).—Poultry sanitation investigations conducted by the Tennessee Experiment Station during the last 6 yr. have led the author to emphasize the importance of several factors, namely, the freedom of poultry from contact with disease-producing microbes and parasites, supply of fresh water and fresh feed free from contamination, use of litter in clean houses, and the prevention of contact with infected or infested fowls.

**Studies on incubator hygiene, VI—VIII**, R. GRAHAM and V. M. MICHAEL (*Poultry Sci.*, 15 (1936), No. 6, pp. 490-495).—The continuation of this contribution (E. S. R., 75, p. 260) is presented in three parts.

**VI. A note on the resistance of *S[almonella] pullorum* on sterilized and unsterilized egg shells** (pp. 490, 491).—In three separate fumigations of a forced-draft incubator (formaldehyde released from cheesecloth 20 cc per 100 cu. ft.), "there appeared to be very little variance in the longevity of *S. pullorum* on eggshells which had been sterilized at 15 lb. steam pressure for 30 min. and for those which had not been sterilized previous to contamination with *S. pullorum*. *S. pullorum* on eggshells in hatching trays survived formaldehyde fumigation for 30 min. After 40 min., *S. pullorum* was generally nonviable, although in one fumigation it survived for 100 min. on sterilized eggshells. The survival of *S. pullorum* on eggshells during formaldehyde fumigation of a forced-draft incubator for 100 min. suggests the advisability of keeping the incubator closed for at least 2 hr. following fumigation. The range of

*S. pullorum* viability in empty incubators, as previously reported (E. S. R., 70, p. 835), appears comparable to the results of these experiments in which a 32,000 capacity incubator carried 6,000, 15,000, and 20,000 eggs. In 25 separate fumigations, however, *S. pullorum* that occasionally survived 40-min. fumigation may have had a range of 100 min."

VII. *Results of fumigation of S. pullorum in incubators at full capacity* (pp. 492, 493).—The studies reported have shown "that formaldehyde fumigation is probably as effective in destroying *S. pullorum* in a forced-draft incubator operated at 50 or 66 percent egg capacity as in an incubator that is practically empty, since the average survivability of *S. pullorum* and range survivability proved comparable. In one instance *S. pullorum* survived for 150 min. in the lower door and 120 min. in the upper door, and proved nonviable at 180 and 150 min., respectively."

VIII. *The resistance of S. aertrycke, S. anatum, and Salmonella from quail to formaldehyde fumigation* (pp. 494, 495).—In the fumigation work reported, *S. aertrycke* and *S. newport* on cotton squares survived formaldehyde fumigation in a forced-draft incubator for 30 min. but was not viable at 60 min., while the quail *Salmonella* survived for 60 min. but was not viable at 90 min.

[The use of anthelmintics for the control of avian parasites] (*Arkansas Sta. Bul.* 337 (1936), pp. 40–42).—The work of the year (E. S. R., 74, p. 857), by W. L. Bleeker and R. M. Smith, is briefly noted.

Studies in coccidiosis in chickens: Calcium carbonate additions and coccidia, C. E. HOLMES, C. A. HERRICK, and J. L. OTT (*Poultry Sci.*, 15 (1936), No. 5, pp. 416, 417).—In the further study of coccidiosis (E. S. R., 76, pp. 107, 251) at the Wisconsin Experiment Station, Single Comb White Leghorn chicks were brooded in sterile cages, fed sterilized rations, and reared under conditions that made infection impossible. "Zero, 3, and 6 percent of chick size oystershell was added to the rations of the three groups in each trial, and controlled infections of coccidiosis were made at three different ages. Infection was accomplished by pipette feeding of measured amounts of sporulated oocysts of a pure culture of *Eimeria tenella*. These trials seem to indicate that excessive mineral additions are likely to be detrimental to growing chicks if the chicks become infected with coccidiosis."

Cultivation of the virus of infectious bronchitis, F. R. BEAUDETTE and C. B. HUDSON (*Jour. Amer. Vet. Med. Assoc.*, 90 (1937), No. 1, pp. 51–58).—Studies by the New Jersey Experiment Stations of a respiratory disease of chicks, encountered in January 1935 in a broiler plant having a total population of about 40,000 of all ages, are reported upon. A review of the literature is said to have shown that the affection is undoubtedly the same as that reported upon by Schalk and Hawn in 1931 (E. S. R., 65, p. 271) in North Dakota, Bushnell and Brandy in 1933 (E. S. R., 68, p. 820) in Kansas, and Beach and Schalm in 1936 (E. S. R., 76, p. 106) in California, for which, to distinguish it from laryngotracheitis, the name infectious bronchitis has been recommended (E. S. R., 76, p. 396). It was found that when introduced intratracheally and intranasally the virus, which passes all grades of Berkefeld filters, regularly provokes the disease. "Subcutaneous and intramuscular inoculations are either noninfective or else produce the disease after a prolonged incubation period. Inoculated into the chorioallantoic membrane of the developing embryo, the virus does not produce gross lesions such as are produced by the viruses of laryngotracheitis, fowl pox, and pigeon pox. The absence of such lesions could be used to distinguish between the viruses of laryngotracheitis and bronchitis. After a few passages, the virus developed the capacity to kill the embryo. The embryo appears smaller than embryos of the same age from eggs in which pox and laryngotracheitis viruses have been cultivated. After passage through 14

generations, the virus was infectious for chickens that were immune to laryngotracheitis. Likewise, birds recovered from bronchitis were still susceptible to laryngotracheitis. The serum of birds recovered from bronchitis is capable of neutralizing the virus."

**Studies of the clinical manifestations and transmissibility of infectious coryza of chickens,** J. R. BEACH and O. W. SCHALM (*Poultry Sci.*, 15 (1936), No. 6, pp. 466-472, figs. 3; abs. in No. 5, p. 416).—In further work at the California Experiment Station (E. S. R., 75, p. 110; 76 p. 106), "infectious coryza was found to occur as a simple coryza manifested only by a nasal discharge or as a coryza with complications consisting of edematous swelling of the face, sinusitis, conjunctivitis, tracheitis, bronchitis, and infection of the air sacs. The disease was easily transmitted by inoculation of normal chickens with exudative material from any infected part or by direct contact exposure of healthy fowls to diseased ones. Transmission of the disease by indirect contact was accomplished but did not take place readily. Cages contaminated by occupancy by diseased chickens and by having virulent exudate from infected chickens placed in the feed and water vessels did not remain infective to susceptible chickens placed in them for longer than 24 hr. The disease was transmitted by inoculating healthy chickens with scrapings of the nasal mucosa of chickens which had been infected with coryza but had shown no symptoms for as long as 46 days. Pigeons were found to be refractory to the disease. Three turkeys which were tested were found to be susceptible, and the resultant disease was of the same character as natural cases of coryza and sinusitis in this species of bird."

**Studies of infectious coryza of chickens, with special reference to its etiology,** O. W. SCHALM and J. R. BEACH (*Poultry Sci.*, 15 (1936), No. 6, pp. 473-482, figs. 6; abs. in No. 5, p. 416).—In a continuation of the work at the California Experiment Station on the etiology of infectious coryza (E. S. R., 76, p. 106), transfer at intervals of less than 14 days was found necessary for the maintenance of slant or plate cultures of *Hemophilus gallinarum*. Stock cultures were maintained indefinitely by making transplants once a week. It is concluded that "the minimum temperature at which *H. gallinarum* will grow in culture is 25° C., the maximum temperature is 45°, and the optimum temperature range is from 34° to 42°."

"The injection of pure cultures of *H. gallinarum* into the respiratory tract of fowls produces a coryza with symptoms identical with those of the natural or exudate-induced disease but of much shorter duration. Attempts to determine whether the longer duration of the natural or the exudate-induced disease was due to the presence in the exudate of types of bacteria other than *H. gallinarum* or of a filtrable virus yielded negative results. A mild culture-induced coryza of only 2 days' duration, by rapid serial passage through chickens, increased in virulence and severity until it was of the same character as that produced by exudate obtained from severe field cases. This increase in virulence and severity occurred without the introduction of any pathogenic agent other than the culture *H. gallinarum* with which the series of passages was initiated. The results are regarded as evidence that the mild character of the culture-induced disease is due to a decrease in virulence of the organism on artificial media, and that the virulence can be restored by continued cultivation in the more favorable environment of the nasal passages of susceptible chickens."

**Differentiation of paralysis in chicks,** E. JUNGHER (*Poultry Sci.*, 15 (1936), No. 5, pp. 415, 416).—In this further contribution from the [Connecticut] Storrs Experiment Station on paralysis (E. S. R., 73, p. 109), differentiation by histologic means is considered. Chicks sacrificed for examination and found

to be free from demonstrable bacterial or parasitic diseases served as the source of tissue material. The results are summarized in a table. Of the conditions listed, namely, gout, crazy chicks, A avitaminosis, G avitaminosis, epidemic tremor, neurolymphomatosis, and field encephalomalacia, all except field encephalomalacia have been described in the literature. Although the true cause of gout is regarded as unknown, the work of other investigators and the author's observations indicate that sodium bicarbonate can cause a disease indistinguishable from it. It is pointed out that the term "crazy chick", popularly applied to various conditions, should be restricted to the nephritic ataxia described by Dunlap (E. S. R., 67, p. 748), it being rarely found if histologic changes in freshly killed chicks are used as the diagnostic criterion. The hitherto undescribed field encephalomalacia of unknown etiology was the most interesting condition encountered. Well-grown birds between 3 and 7 weeks showed droopiness, retraction of head or trembling of legs, and, at autopsy, characteristic gross affection of the brain by edema and cerebellar hemorrhages. The condition resembles in gross and histopathologic features the nutritional encephalomalacia of Pappenheimer and Goettsch (E. S. R., 69, p. 719), but seems to differ in occurring on feeds, presumably containing the anti-encephalomalalytic factor, and in being influenced therapeutically by methylene blue instead of vegetable oils.

**Serological types of *Salmonella* isolated from paratyphoid in chicks, E. JUNGHERR and A. G. BORDEN** (*Jour. Bact.*, 32 (1936), No. 1, p. 127).—During the routine diagnosis of chick diseases at the [Connecticut] Storrs Experiment Station five cases of paratyphoid infection were observed in 1935 and 1936, although no cases had been diagnosed during the preceding 4 yr. Paratyphoid-like organisms were isolated from several chicks of each specimen lot and recognized as the etiological agents. Biochemical tests placed these organisms in the genus *Salmonella*. Strains determined to be smooth variants on the basis of morphology, colonial characteristics, boiling, salt sensitivity, and Pampana tests were subjected to serological analysis by the Kauffmann-White scheme (E. S. R., 72, p. 534). Two of the organisms were found to resemble the one recently isolated by Jungherr and Wilcox (E. S. R., 73, p. 110) and by Edwards (E. S. R., 74, p. 548). "These organisms belong to group B and are now known as *S. typhi-murium* var. *storrs*. Two of the isolated organisms were shown to belong to group C, resembling *S. cholerae suis* in the specific phase, and one strain was found to belong to group E, resembling *S. london*. The group C organisms differed from true *suipastifer* strains in fermenting arabinose, and the group E culture differed from *S. london* in failing to ferment inositol. The group E organism was able to absorb all antigenic factors from a known *S. london* serum and vice versa, but further tests are necessary to establish identity."

**The occurrence of *Salmonella*, Oranienburg type, in an infection of quail, P. R. EDWARDS** (*Jour. Bact.*, 32 (1936), No. 3, pp. 259–263).—In work at the Kentucky Experiment Station the author identified an organism occurring in an epizootic among baby quail, resulting in the death of large numbers on the State quail farm in Illinois, as *Salmonella*, type Oranienburg. It is said to constitute the first recognized occurrence of this type in diseases of animals.

## AGRICULTURAL ENGINEERING

[Agricultural engineering investigations by the Department of Agriculture, 1936] (*U. S. Dept. Agr., Sec. Agr. Rpt.*, 1936, pp. 95–98, 113–115).—Progress results are briefly presented of investigations on improved farm equipment, potato storage, irrigation and snow surveying, and road construction.

**Report of the Chief of the Soil Conservation Service, 1936, H. H. BENNETT** (*U. S. Dept. Agr., Soil Conserv. Serv. Rpt., 1936, pp. 52*).—This report presents the progress results of the work of the Soil Conservation Service during 1936, with particular reference to field and conservation operations, research, and cooperative relationships. The research program related to six closely coordinated lines of investigation in the factors involved in soil and water conservation and was organized to be cooperative with the State agricultural experiment stations.

[**Agricultural engineering investigations by the Arkansas Station**], D. G. CARTER, R. P. BARTHOLOMEW, L. C. KAPP, W. C. HULBUET, and R. M. SMITH (*Arkansas Sta. Bul. 337 (1936), pp. 12, 13, 26, 27, 40*).—Progress results are briefly presented of investigations on farmhouse planning and design, durability of posts and methods of preservative treatment, water resources for rice irrigation, cost of terracing, erosion control, and poultry housing.

[**Agricultural engineering investigations by the Michigan Station**] (*Michigan Sta. [Bien.] Rpt. 1935-36, pp. 5, 6*).—Progress results are briefly presented of investigations on low cost paints and surface treatments, lime-treated shavings and sawdust for insulation, the use of a stem crusher as an aid in curing leguminous hay, designing a universal type cultivator, and the conversion tractor.

[**Agricultural engineering investigations by the Missouri Station**], J. C. WOOLEY, M. M. JONES, and G. W. GILES (*Missouri Sta. Bul. 370 (1936), pp. 27, 28, fig. 1*).—The progress results are briefly presented of investigations on poultry houses, terrace outlet structures, and the economy of various tillage methods for the growing of corn in Missouri.

[**Agricultural engineering investigations at the Montana Station**] (*Montana Sta. Rpt. 1935, pp. 28, 29, 47, 48, figs. 2*).—Progress results are briefly presented of investigations on the development of water reservoirs on the range and of a homemade double intake centrifugal pump for irrigation.

**A selected bibliography on upstream engineering** (*U. S. Dept. Agr., Soil Conserv. Serv., 1936, pp. [2]+6*).—This mimeographed bibliography, prepared for the Upstream Engineering Conference (E. S. R., 75, p. 577), contains about 70 references to literature on the subject.

**Forest and agricultural influences in streamflow and erosion control**, W. C. LOWDERMILK (*U. S. Dept. Agr., Soil Conserv. Serv., [1936], pp. [1]+37+4, fig. 1*).—This is a mimeographed summary review of literature up to 1930, the purpose of which is to set forth briefly the status of conclusions of investigators who have studied the problem and of experimental information on the subject as found in European and American literature.

**Soil erosion and its control**, Q. C. AYRES (*New York and London: McGraw-Hill Book Co., 1936, pp. XI+365, figs. 244*).—This is a general treatise on the subject of erosion control, in which an attempt is made to bring together a general introduction to and correlation of all phases of the problem with the quantitative application of such data as are known at present. The author points out that the apparent disproportionate emphasis accorded to engineering phases of erosion control is partly attributable to the fact that more information of a practical and time-tested nature is available from that standpoint. Chapters are included on factors affecting rate of erosion, methods of control, rainfall and run-off, terrace design, terrace location—principles and practice, terrace construction methods and machinery, terrace construction costs and maintenance, terrace outlets, control of gullies, temporary and semipermanent check dams, permanent or soil-saving dams, special uses of vegetation, and soil conservation and land use. An appendix deals with simple methods of calculating

land areas, partial lists of soil conserving and depleting crops and of plants favorable to soil conservation and wild life, and other data.

**Public Roads, [December 1936]** (*U. S. Dept. Agr., Public Roads, 17 (1936), No. 10, pp. [2]+223-248+[1], figs. 13*).—This number of this periodical contains data on the status of various highway projects receiving Federal funds as of November 30, 1936, data on the disposition of State motor fuel, motor vehicle, and motor carrier receipts and receipts from State imposts on highway users, 1935, and an article entitled Determination of Coefficients of Friction of Sliding Bearings for Bridges, by G. W. Davis (pp. 223-237).

**Procedure for making soil conservation surveys.**—Outline No. 4, approved by G. L. FULLER (*U. S. Dept. Agr., Soil Conserv. Serv., 1936, Outline 4, pp. III+32*).—Instructions are presented for use in making soil conservation surveys, including surveys on Soil Conservation Service projects. The instructions relate to base maps, symbols, differentiation of the four major land classification factors for conservation surveys, and reports.

**Model traffic ordinances** (*U. S. Dept. Agr., Public Roads, 1936, pp. VIII+30*).—These ordinances, presented as revised and approved by the Fourth National Conference on Street and Highway Safety, May 23-25, 1934, consist of part 1, a model municipal traffic ordinance; part 2, a model traffic administrative ordinance; and part 3, State law provisions which might be included in the traffic ordinances.

**The corrosion of cement.**—I, Portland cement and water, E. B. R. PRI-DEAUX and B. G. LIMMER (*Jour. Soc. Chem. Indus., Trans., 54 (1935), No. 42, pp. 348T-354T, figs. 5*).—Studies are reported in which conductivities and hydroxyl-ion concentrations (as pH by the hydrogen electrode) were used to determine the concentrations of calcium hydroxide dissolved from the pure solid as a standard. The solubility of pure lime obtained by these methods and potentiometric titration was found to be in good agreement with results of previous workers. The conductivity method thus standardized was found to be the more delicate in following slight changes of concentration. These methods were then applied to an investigation of the corrosion of portland cement by pure water, it having been found that the presence of aluminates and calcium sulfate dissolved from the cement had relatively slight effects. Cylinders of neat cement were extracted with water under various conditions, and figures were obtained for the amounts of lime removed per unit surface of cement and volume of solution. For the same times these amounts increase with increase in the ratios surface of cement : volume of solution. The initial effect of an inert aggregate on rate of corrosion was negligible, but in the later stages this rate was lower for a concrete than for a neat cement. Rates of removal of lime and concentrations of extracts were compared in the cases of pats and powders, respectively. About a quarter of the weight of powdered cement was removed by successive extractions with water. The most important factor governing the percentage dissolved is the ratio of volume of water : surface of cement. The rate of corrosion of massive pieces in the early stages resembles the rate of dissolution of a pure substance, but in the later stages it appears to be more determined by rate of diffusion of lime through the surface of the solid. A typical hard water was found to remove more lime than pure water under the same conditions, and the (sulfate) hardness of the water was thereby reduced.

**The calorific value of decayed cordwood,** M. T. HILBOEN (*Phytopathology, 26 (1936), No. 9, pp. 905-914, fig. 1*).—In studies conducted at the Maine Experiment Station, the effect of decay on specific gravity and calorific value was measured in split and unsplit wood of red maple, paper birch, and beech in two types of situations over a period of 4 yr.

Specific gravity of the wood when air dried was found to be higher in split wood, presumably from trunks, than unsplit wood, presumably from branches. As the specific gravity decreased the calorific value of the wood, air-dried, also decreased somewhat, indicating a change in chemical composition. The calorific value decreased somewhat faster in the woods than in an open field, faster in the split than in the unsplit form, and respectively more rapidly for the maple, beech, and birch in the round form. Correcting the calorific value for water content, which increased with decay, the net, or practically useful fuel value was found to decrease in 4 yr. as much as 89.4 percent for the round white birch from the woods, and as little as 35.9 percent for the round red maple from the open field. The decrease was as much as 50 percent in less than 2 yr. in some of the birch wood.

**Effect of tetraethyllead on preflame reactions in an engine**, L. WITHROW and G. M. RASSWEILER (*Indus. and Engin. Chem.*, 27 (1935), No. 8, pp. 872-879, figs. 6).—Studies conducted by the General Motors Research Division are reported. Absorption spectra of the gaseous charge in an engine indicate that when tetraethyl lead is added to the fuel to prevent knock there is an effect on the preflame reactions in that portion of the charge which, in the absence of tetraethyl lead, suddenly inflames at the time of knock. Atomic lead has been identified in the noninflamed charge in the knocking zone at the moment that antiknock action is being effected, but no accompanying absorption by lead monoxide has been observed. When lead is vaporized in a hot nichrome tube the absorption spectra exhibit lead monoxide bands at lower temperatures than atomic lead lines. Comparison of experiments in and out of the engine indicates that lead monoxide is being reduced in the noninflamed charge.

**Using water in tractor tires to increase drawbar pull** (*Impl. and Tractor*, 51 (1936), No. 20, p. 30).—Investigations are reported which indicate that the use of water within tractor tires is entirely satisfactory for additional weight requirements in field service. In describing the equipment required to induce water under pressure, it is pointed out that water under 50 lb. pressure will flow through the connections and the valve stem at the rate of about 20 lb. per minute. The use of water-filled tires in temperatures low enough to cause the formation of hard ice necessitates the use of antifreeze solutions.

**A telescoping wagon tongue**, C. K. SHEDD and E. V. COLLINS (*Agr. Engin.*, 17 (1936), No. 8, pp. 343-345, figs. 4).—In connection with the studies of corn production machinery at the Iowa Experiment Station, a telescoping wagon tongue was developed which is here described and illustrated. Working drawings also are included. This work was done in cooperation with the U. S. D. A. Bureau of Agricultural Engineering.

**Unit heaters in greenhouses**, A. H. SENNER (*Agr. Engin.*, 17 (1936), No. 8, pp. 333-336, 340, figs. 8).—Studies conducted by the U. S. D. A. Bureau of Agricultural Engineering are reported, the objects of which were (1) to determine the relative steam consumption of unit heaters and conventional pipe coils for heating a greenhouse; (2) to compare the distribution of temperature with the two types of heating; and (3) to determine the relative quantities of steam required during the daylight and night periods, respectively, and to arrive at a knowledge of the steam consumption per degree-day per 1,000 sq. ft. of equivalent glass area. The data are presented mainly in graphic form.

A striking result of the study was the fact that more uniform temperature distribution was maintained throughout the experimental greenhouse by means of coils than by unit heaters. From actual measurements taken during the study it was possible to establish certain constants. It was found, for example, that 20 lb. of steam are required per 1,000 sq. ft. of glass or equivalent per

degree-day in heating a greenhouse such as the one under test and located in those regions which have solar heating characteristics.

**Equipment for applying dust fungicides to seed grain,** W. M. HURST, F. D. FULTON, W. R. HUMPHRIES, and R. W. LEUKEL (*U. S. Dept. Agr. Circ. 415* (1936), pp. 20, figs. 12).—The equipment described includes commercial treaters and experimental feeders. General precautions for handling fungicides are included.

**Engineering phases of pink bollworm control,** D. A. ISLER (*Agr. Engin., 17* (1936), No. 8, pp. 346-348, figs. 6).—In a brief contribution from the U. S. D. A. Bureau of Agricultural Engineering, it is pointed out that the engineering phases of present investigations for effective field control of the pink bollworm include (1) development of mechanical equipment for the destruction of worms in the crop remnants, and (2) determining the value of plowing, irrigation, and other cultural practices as control measures.

**Application of sulfuric acid for weed control,** O. C. FRENCH (*Agr. Engin., 17* (1936), No. 8, pp. 339, 340, figs. 4).—In a brief contribution from the California Experiment Station, the results of tests of the mechanical application of sulfuric acid for weed control are presented. In tests on barley fields infested with wild mustard an average increased yield of 50 percent was obtained by treating with a 10-percent solution of sulfuric acid.

The experiments resulted in the development of a sprayer of the portable power take-off type. This unit was equipped with a 20-gal.-per-minute pump and a 400-gal. metal tank, and was mounted on dual pneumatic tires. On the rear of this sprayer a frame was built that held a 50-gal. drum of concentrated acid and also supported an 18-ft. folding boom. A  $\frac{3}{8}$ -in. Penberthy steam ejector was installed in the water discharge line from the pump, just ahead of the spray boom. Water flowing through this ejector under 250 lb. pressure reduced the pressure in the suction side of the ejector sufficiently to draw concentrated acid from the drum.

Nozzles were developed that gave a flat fan-shaped spray. These were placed on the boom 12 in. apart so that when the boom was about 24 in. from the ground the fans overlapped, thus giving a double coverage. Nozzles were alternately tilted so that the spray was directed both forward and backward.

**Some fundamental principles of drying,** E. A. FISHER (*Jour. Soc. Chem. Indus., Trans., 54* (1935), No. 42, pp. 343T-348T, fig. 1).—This is a technical discussion of basic principles involved in the process of commodity drying.

**Modern drying machinery,** T. J. HORGAN (*Jour. Soc. Chem. Indus., Chem. and Indus., 54* (1935), No. 42, pp. 913-924, figs. 11).—This is a technical description of modern drying methods and equipment.

**Hop curing** (*Rural Electr. and Electro-Farming, 12* (1936), No. 137, pp. 95-97, fig. 1).—A brief discussion of the essential factors involved in the process of hop drying is presented, indicating the advantages presented by the use of electrical equipment.

**The dehydration of farm products,** F. E. PRICE (*Agr. Engin., 17* (1936), No. 10, pp. 435-437, figs. 3).—In a brief contribution from the Oregon Experiment Station, the status of artificial dehydration studies at the station is briefly presented, with particular reference to the work with corn and hops.

In a few tests with corn, the amounts of fuel required to reduce the moisture content of green corn from 30 to 12 percent per ton were 15 gal. of fuel oil, 0.14 unit of sawdust, 0.1 cord of fir wood, or 0.09 ton of coal.

**Natural drying of forage crops,** T. N. JONES and L. O. PALMER (*Agr. Engin., 17* (1936), No. 10, pp. 433, 434, 437, figs. 2).—This is a brief statement of the status of the studies at the Mississippi Experiment Station on the natural

drying of forage crops, with particular reference to the natural drying forces which respond to engineering control. A machine combining a mower and crusher is described which was developed in the course of these studies.

**Grass drying** (*Rural Electrification and Electro-Farming*, 12 (1936), No. 137, pp. 92-94, figs. 2).—A process of hay drying which is in use in England and the corresponding equipment are described and details of cost involved presented. The drier is so arranged that grass may be dried in two successive stages by a current of hot air drawn upward through 24-in. beds of grass by means of an electrically driven fan. The grass is laid on trays, placed side by side in drying chambers connected by air passages, and held in position by weighted steel hurdles. During a 25-min. cycle, one tray of grass is partly dried, and the other tray of grass, which has been previously partly dried, is completely dried. When drying is complete, as shown by a thermometer, the dried grass is transferred to the baler and a fresh charge is prepared. Except for short intervals, when the trays are exchanged, drying is continuous. Coke or anthracite coal is burned in a steel chamber lined with firebricks to provide the necessary hot air for drying.

**Moisture content at which alfalfa leaves shatter**, F. J. ZINK (*Agr. Engin.*, 17 (1936), No. 8, pp. 329, 330, figs. 4).—Studies conducted at the Kansas Experiment Station in connection with research on the development of hay drying methods and equipment are briefly reported. The general procedure of the tests involved studies of periodic samples of hay as it dried normally in the swath. The results indicate that as alfalfa hay approaches 30 percent moisture there is considerable danger of losing the leaves.

It is concluded that shattering occurs before the hay is sufficiently dry for storage, indicating the possibility of night, evening, or morning operations as a means of securing improved quality. Where hay is dried artificially it appears possible to permit it to remain in the field without loss of dry matter until an average moisture content of around 40 percent is reached, thereby effecting considerable fuel economy.

**Storing chopped alfalfa hay in ventilated containers**, B. H. ROCHE (*Amer. Soc. Anim. Prod. Proc.*, 1935, pp. 259-262).—This is a brief presentation of results of experiments conducted at the Wisconsin Experiment Station.

It was found that chopping hay at the time of storing in the barn or in ventilated containers has many advantages. The investigations were conducted with six wooden bins on a weighing track. These bins varied from 3 to 6 ft. wide, 7 to 8 ft. long on the inside, and 10 ft. deep, and a larger bin was 9 ft. wide, 15 ft. long, and 12 ft. deep. The side and end walls were double with 1" by 2" slats spaced 1 in. apart making up the inside wall, while the outer wall was of matched boards. There was an air space of 6 in. between the walls with openings to the outside at all four corners, allowing free movement of air between the slatted and the solid walls. The floor was tight. In addition to the wooden units, an all metal unit (with the exception of the floor and end sections which were wood) was used. This provided a double-walled container comparable to some commercial chopped hay storage structures. It was made of galvanized steel sheets with louvers (perforations) on the inside wall next to the hay and tight metal sheets for the outside walls. The design of the two metal walls was such as to permit a vertical movement of the air, carrying upward the heat produced in the hay in much the same manner as a chimney.

Chopped alfalfa, both first and second crop, of varying moisture content, was stored in each of the different containers. The hay was run through a silage cutter set on the  $\frac{3}{8}$ -,  $\frac{1}{2}$ -, or 1-in. cut.

With the equipment and length of cut used, it was concluded that in order to retain the maximum nutritive value the hay must be fully as well cured as is the ordinary practice with unchopped hay. However, some evidence was obtained that with a very narrow width of container, more completely ventilated walls, and a longer cut, thus decreasing the density, good results might be secured with hay of slightly higher moisture content.

**Volumes and weights of stacked hay,** H. E. MURDOCK (*Montana Sta. Bul. 327 (1936), pp. 22, figs. 4*).—The results of this study indicate that the actual volume of a haystack as ordinarily built can be closely estimated from measurements, but that the unit weight of hay varies between wide limits. A satisfactory mutual agreement should be entered into by the buyer and seller of stacked hay as to the method of arriving at the market value of a given volume of hay. The rate of settlement of hay is rather rapid for the first few weeks after it is stacked, after which time the volume remains fairly uniform until the hay is further packed by the winter snows and spring rains. This rate is apparently independent of the kind of hay, the stacker used, and the year. Rather definite relations were established between the volumes of a given stack at different ages. The range in the average weight per cubic unit of different kinds of hay is large. The range in the average weight per cubic unit of any one kind of hay is also large, and no rule can be made that will give an accurate estimate for any given stack. When a large amount of stacked hay is purchased the measurement of the stacks and estimate of weight may be fairly accurate, but where only a few stacks are involved there is much greater chance for error and weighing should be resorted to if at all possible.

[**Dust explosion and spontaneous ignition of hay investigations**] (*U. S. Dept. Agr., Bur. Chem. and Soils Rpt., 1936, pp. 29-32*).—Progress results are briefly reported.

**Farm building costs and appraisals,** G. R. HANSON (*Agr. Engin., 17 (1936), No. 10, pp. 413-416, 422, figs. 5*).—This is an analysis from the U. S. Resettlement Administration.

**Inspection and appraisal of farm buildings for insurance purposes,** E. D. ANDERSON, C. H. FRICK, and L. G. KEENEY (*Agr. Engin., 17 (1936), No. 10, pp. 417, 418, 425, fig. 1*).—Modern methods in the appraisal of farm buildings for insurance purposes are analyzed.

**Appraisal of farm improvements,** E. W. LEHMANN (*Agr. Engin., 17 (1936), No. 10, pp. 419-422, figs. 2*).—This contribution from the Illinois Experiment Station points out five main considerations in the appraisal of farm improvements, these involving the engineering phases, the requirement for improvements on a farm as a going concern, the cost of reproducing improvements, the depreciation, and the actual value of improvements on the farm as a producing industry.

**Masonry barn design and construction,** H. GIESE, H. J. BARRE, and J. B. DAVIDSON (*Iowa Sta. Res. Bul. 207 (1936), pp. 253-297, figs. 34*).—This bulletin reports the results of a study initiated in 1913 of the design of an all-masonry barn which might be constructed at reasonable first cost with the advantages of permanent and fire-resistant construction. The studies were confined largely to the roof. In addition to a number of design studies, models of roof sections were built to develop a method of roof construction. Strength tests were made on these models to check the reliability of the designs. The information obtained served as the basis of the design and method of constructing an experimental barn, which was built at Iowa State College in 1926-27. The results indicate that the masonry arch is a very stable type of roof structure. The tests on sections were found to check the design calculations closely.

The construction of the roof was found to be difficult and involves a large amount of labor because of (1) the use of heavy steel forms to carry a large

part of the roof weight; (2) the manipulation of the forms in erection, moving, dismantling, and transporting; and (3) the handling and placing of roof materials.

The additional cost of the roof over a wood frame type construction is due not so much to the cost of materials as to the cost of the unproductive labor in handling the materials and in manipulation of the steel forms. The overhead cost of the forms becomes a large item in the first cost if they are used for only one or a few barns.

Experiments in the methods of making a roof watertight have not as yet indicated an entirely successful method. A heavy-fibered asphalt has been found the best of the waterproof coatings which have been used. Leaks appear to be due to slight openings in the joints and to the development of fine cracks.

A roof with a span of 34 ft. and a height of 20 ft. provides enough storage space for most conditions.

An important feature of this publication is the contribution it makes toward the principles of design of reinforced concrete arches as they relate to a roof suitable for a barn. Special attention is given to size, shape, and loading, and the structural principles relating to these are mathematically and graphically expressed.

**Electrical ventilation for livestock structures**, C. H. JEFFERSON and D. G. ERINGER (*Michigan Sta. Quart. Bul.*, 19 (1936), No. 2, pp. 81-87, figs. 4).—Technical information is given on the design, installation, and operation of electrical ventilation systems for livestock structures.

## AGRICULTURAL ECONOMICS

[Investigations in agricultural economics by the Arkansas Station, 1935-36] (*Arkansas Sta. Bul.* 337 (1936), pp. 65-69).—Results of investigations not previously noted are reported by C. O. Brannen as to decreases in real estate and personal tax delinquencies from 1933 to 1935 and as to the sources of county funds and the expenditures for roads, indebtedness, and other purposes in 1931 and 1932; by R. B. Craig and O. J. Hall, as to the burden of ad valorem taxes on producing and cut-over forest lands; as to receipts, expenses, taxes, and changes of inventory on 396 selected farms in 1935; by Hall, as to the use of lands rented by the Agricultural Adjustment Administration in 1934 and the number of applications to redeem, donate, and purchase State-owned lands in the years 1927-35 and from January 1 to June 9, 1936; and by H. W. Blalock, in a study of 89 representative cotton plantations, in cooperation with the Works Progress Administration, as to labor income of landlords and tenants, the sources of the income of tenants, and the expenditures for food, clothing, health, and other purposes by tenants.

[Investigations in agricultural economics and farm management by the Missouri Station, 1934-35] (*Missouri Sta. Bul.* 370 (1936), pp. 23-26, 73).—Results of investigations not previously noted are reported briefly as follows: Findings (1) by B. H. Frame as to the contribution of farms to family living on 72 Atchison County farms and the average receipts, expenditures, and labor income on 30 farms in 1934 in the same county; (2) by O. R. Johnson and Frame as to the adjustments in the cropping systems due to production control on 316 Atchison, Nodaway, and Linn County farms; (3) by C. H. Hammer and H. Jenny as to the use of a differential system of land classification; and (4) by H. L. Kempster on the feed-purchasing power of eggs.

**The world agricultural situation in 1934-35** (*Roma: Internatl. Inst. Agr.*, 1936, pp. VIII+533+[1]).—This volume, the sixth in the series previously noted

(E. S. R., 76, p. 410), is a commentary on the International Yearbook of Agricultural Statistics for 1934-35 noted on page 712. Part 1, world agriculture, discusses the changing structure of world economy and the economic conditions of agriculture and summarizes the position and tendency during the year of the international market for cereals, sugar, coffee, tea, wine, grapes, olive oil, tobacco, textile materials, livestock, and livestock products. Part 2, agricultural policy and conditions in the different countries, follows the same general plan as in previous volumes.

**Income in agriculture, 1929-1935**, R. F. MARTIN (*New York: Natl. Indus. Conf. Bd., Inc., 1936, pp. XVIII+168, [figs.] 17*).—This volume summarizes the results of an analysis of official and other statistics relating to agricultural income and purchasing power in chapters on gross income in agriculture, other income of farm operators, taxes and interest, rent and depreciation, wages, and other current operating expenses, net agricultural income of farm operators, income parity for agriculture, purchasing power parity for agriculture, and comparative income status of farm operators. Appendixes include a description of the sources of data and methods used in the study and evaluations of the census of agriculture and the U. S. Department of Agriculture's estimates of agricultural income as sources of income data.

"These data indicate that in 1929 the net occupational incomes of farm operators were about on a par with those of other gainfully occupied groups in most regions of the country, and considerably higher in some regions. Available data for later years indicate that there was an income disadvantage for farm operators as compared with fully employed persons in manufacturing and retail trade, but that farmers were about on a par with salary and wage earners as a whole. A further general finding is that pronounced variations in the comparative income status of farm operators occur from year to year in the different regions in response to special conditions of agricultural production, as in the case of droughts, and market influences, such as unfavorable prices in foreign markets for certain export products. This would suggest that the farm problem in the United States, insofar as it does not relate to temporary regional disasters, such as drought or insect damage, or to drastic general economic depressions, is not a longstanding problem of income disparity requiring the forced diversion of income from other gainfully occupied persons to farm operators. It does not differ from that of the rest of the national economy. The problem is to increase employment and productivity in all industries, including agriculture, and to facilitate the flow of income and goods and services to the whole population."

**Farm buying and industrial recovery** (*U. S. Dept. Agr., Agr. Adjust. Admin., 1936, pp. III+22, fig. 1*).—This is a survey of shipments of manufactured and industrial commodities from manufacturing areas to agricultural areas from July 1, 1932, to June 30, 1935. It includes only carlot shipments, but these constituted over 95 percent of the total weight of all shipments. The information was obtained by a study of over one-half million freight waybills and waybill abstracts in the freight auditors' offices of 16 railroads which handle approximately 75 percent of the traffic in manufactured commodities delivered to the agricultural regions. The commodities studied were divided into four main groups—(1) agricultural, commodities used principally in farm production; (2) domestic and personal, commodities used principally in the home, whether urban or rural; (3) industrial and commercial, commodities used primarily in industrial and commercial activities; and (4) general, commodities used generally on farms, in homes, and in industry. Tables show for the years ended June 30, 1933, 1934, and 1935, the total shipments for each group of commodities and for all groups;

the shipments in each commodity group and all groups into the southeastern, southwest, and northwest regions; and the shipments by States of origin to all regions and to the southeast, southwest, and northwest regions.

**Type of farming [in Delaware],** M. M. DAUGHERTY (*Delaware Sta. Bul.* 203 (1936), pp. 7, 8).—Studies of the statistical trends of crops and livestock grown in the State, of varieties and plantings of apples and peaches, and of shipments of feeds into the State are reported.

**Agricultural economic conditions in Iowa, 1935,** T. W. SCHULTZ (*Iowa Yearbook Agr.*, 36 (1935), pp. 249–285, figs. 20).—The status in 1935 of farm income, prices of farm products, prices paid by farmers for commodities used in living and production, wages of farm labor, farm taxes—total and for highways and schools, farm indebtedness, farm capital structure, tenure of farmers, tenancy, etc., are discussed and comparisons made with other years or periods.

**Farm organization and management in Webster County,** J. A. HOPKINS (*Iowa Sta. Bul.* 350 (1936), pp. 365–408, figs. 7).—This study was made to determine the types of farm organization best adapted to the utilization of land and other farm resources in Webster County, and the results are applicable to a large degree to the southern part of the Iowa cash-grain area. It is based on the detailed studies of organization and management of 26 farms in 1928, 39 in 1929, and 49 in 1930. The crop system and livestock industry of the area are described, and effects of tenure on type of farm, crops produced, rotations, disposition of crops, and the hog and cattle industry are discussed. Analysis is made of the income and expenses on the farms studied.

Crop-share tenants had a higher percentage of land in corn and usually a smaller number of livestock per farm than owners. Crop rotation differed little between types of farms but considerably within each type. Cash-grain farms sold, on an average, 11 bu. each of corn and oats for each acre in the farm, general farms 6 and over 7 bu., respectively, and hog farms 4 and 6 bu., respectively. The four beef-feeding farms studied bought 9 bu. of corn and sold 2 bu. of oats per acre in the farm. About 70 percent of the corn and 45 percent of oats grown on hog farms were fed on the farm, 60 and 40 percent, respectively, on general farms, and 40 and 20 percent, respectively, on crop farms. About two-thirds of the corn fed in each case was fed to hogs. Of the total income of the farms studied, 41 percent on hog farms and about 25 percent on crop and general farms came from the sale of hogs; 15 percent on hog farms, 20 percent on general farms, and 5 percent on crop farms from cattle sales; and 28 percent on hog farms, 34 percent on general farms, and 59 percent on crop farms from the sale of crops. The net cash income for 1928 and 1929 on farms of comparable size varied little between the types of farms. The greatest return per \$100 of feed fed hogs was on farms with from 7 to 12 litters of spring pigs and on farms with no fall pigs. Total income and returns per \$100 of feed fed were highest in dairy herds and lowest in beef herds. Returns per \$100 of feed fed increased with beef production per cow up to about 900 lb. in beef herds and to 800 lb. in dual-purpose herds, but decreased with each increase in dairy herds. The returns increased with increased butterfat production per cow up to 240 lb. in dairy herds, to 80 lb. in beef herds, and to 100 lb. in dual-purpose herds. Management returns in 1928 and 1929 averaged \$384 on the farms under 120 acres; \$663, \$1,095, \$972, and \$941, respectively, on hog, beef, crop, and general farms of from 120 to 279 acres; and \$1,731 on farms of 280 acres or more. The livestock sales averaged \$669 higher, crop sales \$514 lower, and net farm income \$710 less on 15 owner farms than on 19 crop-share farms. The management returns, 1928 and 1929, on 120–279-acre farms averaged \$1,770 on the 5 most profitable farms, \$939 on the 5 medium profitable farms, and \$30 on the 5 least profitable farms.

[Investigations in farm management by the Michigan Station, 1934-36] (*Michigan Sta. [Blen.] Rpt. 1935-36, pp. 33-37*).—Included in addition to results previously noted are (1) tables showing the average yield and cost per acre or per head of apples, onions, sugar beets, dairy cows, hens, pullets, feeder lambs and steers, and 2-plow tractors in 1934 and 1935 on farms where enterprise records were kept, and the variation in earnings on 176 farms of different sizes in central Michigan in 1935; (2) average costs, yields, or gains, etc., as shown by cost studies of 80 apple orchards in 1935, 15 lots of feeder cattle, dairy herds in 1934 and 1935, lamb feeders in 1934-35, and poultry in 1934 and 1935; (3) tractor costs in 1934 and 1935; (4) the recommendations for crop and livestock adjustments in the State, based on studies made in 1935.

**Types of farming in Montana.—I, Physical environment and economic factors affecting Montana agriculture,** N. W. JOHNSON and M. H. SAUNDERSON (*Montana Sta. Bul. 328 (1936), pp. 79, figs. 30*).—Ownership and uses of lands; the physical, economic, and biological factors affecting location of farms and ranches and use of land; the geographic distribution of the principal crop and livestock enterprises; and past and possible future adjustments are discussed.

**Land use in New Hampshire,** K. W. WOODWARD (*Jour. Forestry, 34 (1936), No. 11, pp. 975-982*).—Stating that the varied geography of the State results in a great variety of climatic and soil environments, the author discusses past developments and present status and trends of agriculture in New Hampshire and outlines constructive plans for land use and taxation that would promote a permanent and sustained forestry and agriculture.

**A study of the trends of Montana livestock numbers, prices, and profits,** M. H. SAUNDERSON (*Montana Sta. Bul. 329 (1936), pp. 20, figs. 17*).—This bulletin presents "an economic interpretation of the past and recent trends of Montana livestock population, prices, and values, with a background of national supply and demand conditions. Most of the graphic data used cover the years 1890 to 1935." It is based chiefly on Federal and State crop and livestock estimates and studies by the station of livestock prices, production costs, and ranch profits and investment values.

Annual cattle shipments from the State approximated 220,000 head from 1890 to 1915, with little fluctuation from the average, and approximately 350,000 head from 1915 to 1935, but with large fluctuations from year to year. Sheep population increased rapidly to 1900, declined slightly to 1910 and then rapidly to the low point in 1920, and then increased to about the 1890-1935 average (4,000,000 head) from 1930 to 1935. Wool production increased to about 1903, decreased to about 1920, and since 1930 has been about the 1890-1935 average of 28,000,000 lb. Horses increased from 1890 to 1920, and then decreased. Number of swine reached the peak in 1917, and in 1935 was the lowest since 1910. Number of dairy cattle increased to about 1920 and has been about stationary since that time. From 1890 to 1910 there was a rising trend in the value of Montana cattle. The ratio of Montana to Chicago beef cattle prices has gradually declined from about 80 percent in about 1908 to about 60 percent in 1935. There was a steady rising trend in Montana sheep values from 1895 to 1915. Since 1915 the prices have agreed quite closely with those for the United States. Montana wool prices ranged from 10 to 20 ct. per pound from 1890 to 1905. Prices, 1914-35, have fluctuated widely, but since 1933 have been approximately the 1890-1934 average, 23.3 ct. per pound.

**Economic aspects of livestock problems [in Montana]** (*Montana Sta. Rpt. 1935, pp. 30-35, fig. 1*).—Data are included as to the disposition of different kinds of livestock, 1926-31; age at which cattle are marketed; and the relation

of tenure of land, tax delinquency, mortgage foreclosures, and farm credit to the livestock industry.

**Dairy costs and returns in Michigan.** K. T. WRIGHT and A. C. BALTZER (*Michigan Sta. Quart. Bul.*, 19 (1936), No. 2, pp. 75-81, figs. 2).—The results of the fourth year, 1935-36, in the dairy costs study (E. S. R., 74, p. 273) are reported. Complete cost records were kept on 148 herds averaging 13.2 cows.

The average costs in 1935-36 were \$122 per cow, \$1.86 per 100 lb. of milk, and 42.9 ct. per pound of butterfat. The average credits were \$160, \$2.08, and 47.8 ct., respectively. As the average butterfat production per cow increased from 236 to 422 lb., the total costs per pound of butterfat decreased from 41 to 33 ct., and the labor returns per hour increased from 33 to 54 ct. The feed cost per pound of butterfat averaged 12.5 ct. for 30 herds having the lowest cost and 23 ct. for 30 herds having the highest cost. Management returns per herd were over 6 times as much in herds of 26 cows as in herds of 6 cows. Milking machine costs averaged \$3.30 per cow in the 30 herds (averaging 17.8 cows), for which records were available. Total monthly costs per cow ranged from \$12.81 in March to \$8.33 in September. Total income per cow was highest in April and lowest in October, and the net return per cow was highest in June and lowest in October.

**The production-consumption balance of agricultural products in Michigan.—Part 3, Field crops,** G. N. MOTTS (*Michigan Sta. Spec. Bul.* 278 (1936), pp. 30, figs. 5).—This is the third bulletin of the series previously noted (E. S. R., 75, p. 559). Tables, charts, and text show for wheat and wheat flour, rye and rye flour, buckwheat and buckwheat flour, corn, oats, barley, feeds and feed-stuffs, hay, alfalfa and clover seed, field beans, and sugar beets and beet sugar the production in the State, the State's commercial requirements or consumption, shipments to and from other States, etc., by years 1924-25 to 1934-35.

An average of 36 percent of the wheat produced in the State was used for seed, feed, and flour for home use. Sixty percent of the wheat milled in the State was grown in the State. Receipts of wheat from other States exceeded shipments to such States by a yearly average of 2,053,000 bu. From 1920 to 1935 an average of 1,910,000 bbl. of flour was milled in the State, which was less than 47 percent of the estimated State requirements. Thirty-three percent of the flour output of the State was sold in other States, and the receipts from the States averaged 2,789,000 bbl. Rye and buckwheat are minor crops in the State, and the production of both declined from 1924 to 1934. Rye acreage in 1935 increased 44 percent and production nearly 124 percent, due to the increased demand from distilleries. From 1924 to 1932, from 40 to 66 percent of the rye was shipped to other States. Shipments of buckwheat to other States amounted to about one-third of the production from 1924 to 1928 and to one-fourth from 1932 to 1934. The State is a deficit producing State for rye and buckwheat flour. From 1924 to 1934 only 3.2 percent of the corn, 12 percent of the oats, and 10 percent of the barley produced were sold from the farms. Approximately 0.5 percent of the corn, 2 percent of the oats, and from 3 to 8 percent (1929-30 to 1932-33) of the barley was shipped to other States. Oats shipments to other States exceeded receipts from such States. The State is a deficit State as to yellow corn and barley if malting barley is included. From 1929 to 1935, from 5,300,000 to 6,660,000 bu. of white corn were brought in from Illinois and Indiana for cereal manufacture. The State is essentially self-sufficing in hay but is a deficit State for alfalfa and clover seed. The consumption in the State for dry and canned beans is approximately 15 percent of its production. Shipments to other States averaged 2,500,000 bags. The beet sugar output, 1928-35, averaged 45 percent of the consumption in the

State. Shipments to other States exceeded receipts from such States in 3 of the 6 yr. 1928-33. From 1928 to 1933 the consumption of cane sugar in the State amounted to 49 percent of the total sugar consumption.

**Federal seed-loan financing and its relation to agricultural rehabilitation and land use**, N. J. WALL (*U. S. Dept. Agr., Tech. Bul. 539 (1936), pp. 60, figs. 13*)—"The purpose of this bulletin . . . is to present (1) a general history and description of Federal seed-loan financing; (2) an analysis of the financial and economic status of seed-loan borrowers in four southeastern States in 1932, based upon data submitted with seed-loan applications; and (3) a summary of the problems involved in seed-loan financing, with particular reference to the cotton States, together with a suggested approach for effecting a solution of such problems." The beginning and expansion of Federal seed loaning, emergency loans for purchasing feed, loan procedure, the security for loans, and interest rates are described. Analysis is made of factors affecting the cost of making loans, administrative costs, and loss of principal. Using the sample of 480 applications for loans in 1932-40 in each of 12 counties in Virginia, North Carolina, South Carolina, and Georgia—analysis is made of the purpose and size of loans, other indebtedness, size of farm and acreage planted to major crops, livestock and poultry owned, and size of families. Appendixes include the provisions of statutes providing for the various seed loans 1921-35, the amounts of loans and percentage collections by States under the different appropriations, specimen of the application used in making loans in 1932, and a review of the operations of the regional agricultural credit corporations established in 1932.

The analysis of the loan applications showed "(1) the chief use made of loan proceeds has been for the purchase of fertilizer and other farm supplies, a purpose for which merchant credit with abnormally high interest charges was formerly used. (2) The large proportion of loans involving only nominal amounts indicates that the problem of financing the purchase of fertilizer and supplies present obvious difficulties to lending agencies that are solely dependent upon the interest return on their advances to cover the cost of examining the loan application, and in effecting the collection of the loan. (3) The amount of other indebtedness, excluding seed loans, for most of the borrowers, does not appear excessive upon an individual basis. Although this indebtedness in relation to the individual borrower's farm income may be large, data on crop acreage and on livestock and poultry owned suggest that debt-paying capacity may be handicapped by the existing organization of farm operations. (4) The size of farm and the acreage devoted to major crops indicate that the seed-loan problem involves primarily the small farmer, whose operations are chiefly of the subsistence type. (5) The data that show a surprisingly large proportion of borrowers with little or no livestock and poultry owned indicate that increased livestock holdings would improve the standard of living of this group of farmers and reduce their dependence upon credit for the purchase of family food. (6) The average of over five persons in each borrower's family indicates that the financing problems herein discussed are influencing a very large segment of the agricultural population in these four States."

Suggested methods of improving the credit status of chronic seed-loan borrowers include (1) the imposition of certain crop programs, particularly the requirement that feed for work stock and food for the family be raised at home; (2) a study of records of individual borrowers to determine the borrowers' debt-paying capacity and the refusal of credit to borrowers who have not shown a satisfactory attitude toward their debt obligations; and (3) the making of advances under loans in the form of merchandise and supplies,

with a sufficient margin added to the selling price to include the nominal loss ratio that might be anticipated.

**Public expenditures in Oregon by spending units and major functions as measured by tax levies imposed upon general property, W. H. DREESSEN** (*Oregon Sta. Bul. 346 (1936), pp. 142, figs. 23*).—The tax laws of the State are described briefly. Tables show by years 1910–34, inclusive, by counties and counties grouped into four sections—coast, Willamette Valley, southern, and eastern—the weighted average rural and urban tax levies in mills and on equalized valuations for State, county, school, road, debt service, and miscellaneous purposes. Special city levies are also shown in the urban levy tables. Graphs show by counties the increases and percentages of average increases from 1910–13 to 1932–34 in millage levies and by groups of counties and for Multnomah County the weighted average levies by years 1910–34.

There was a general upper trend of rural levies and taxes from 1910 to approximately 1928, followed by a recession during the depression years. The upper trend in urban taxes and levies continued well into the depression years. "Revenues derived from independent sources, especially from income and excise taxes, account for the decline in levies for State purposes during recent years. The recent decline in road levies, both rural and urban, is due to the increasingly larger part played by the State in the construction and maintenance of roads and highways." Total urban general tax levies rose approximately 219 percent from 1910 to 1930 and then declined 17 percent of the 1930 peak to 1934. Rural levies rose approximately 218 percent from 1910 to 1928 and then declined 28 percent from the 1928 peak to 1934. In terms of the 1926 all-commodity index dollar, rural taxes were approximately 267 percent of the 1910 amount in 1932 and 217 percent in 1934. From 1920 to 1930 per capita rural taxes decreased \$7.99 in the coast counties, \$4.98 in eastern Oregon, \$15.92 in southern Oregon, and \$5.48 in the Willamette Valley counties. Per capita public school taxes increased during the period. Total per capita taxes, urban school taxes, and special city taxes rose in all divisions during the period. During the 1910–34 period rural levies for State purposes averaged from 8.6 to 13.7 percent of the total levies in the different divisions of the State, county levies averaged approximately 20 percent, road levies 25 percent, and public school levies from 30.2 to 42.7 percent in the different divisions. Urban levies for State purposes averaged from 5.1 to 9.65 percent in the different divisions and Multnomah County, county taxes from 9.02 to 11.49, and roads from 5.12 to 12.21 percent. Special city and school levies each exceeded 33.33 percent.

**Agricultural prices, F. L. THOMSEN** (*New York and London: McGraw-Hill Book Co., 1936, pp. X+471, figs. 110*).—This textbook assembles in a form suitable for instruction purposes materials on agricultural prices. "The book is not a commentary on the present economic situation of agriculture or of the individual commodities included in the last seven chapters, but a collection of principles designed to prepare the student for making such evaluations in the light of changing supply and demand conditions." The material is arranged in chapters on the application of price information, the demand curve, the supply curve, price determination and discovery, index numbers and measures of changes in demand, relation of agricultural prices to changes in demand and the general price level, the relation of agricultural prices to commodity surpluses, agricultural price-raising measures, methods and materials of price analysis, time elements in prices, graphic multiple correlation in price analysis, analysis of trends, cycles, and seasonal variation, the relation between cash and futures prices, and price forecasting and the preparation of outlook reports. Seven additional chapters on prices of individual commodities—hogs, beef cattle, sheep and wool, dairy products, poultry and eggs, grain, and cotton—are also included.

**Early developments in cooperative cotton marketing**, O. W. HERMANN and C. GARDNER (*Farm Credit Admin.* [U. S.], *Coop. Div., Circ. C-101* (1936), pp. 11+46, figs. 10).—The development of cooperative cotton marketing under the Grange and Farmers Alliance, the activities of early cotton associations, the cotton marketing efforts of the Farmers Union, the development of independent associations, the organization of the American Cotton Association, large-scale State and regional associations, the American Cotton Growers Exchange and the American Cotton Cooperative Association, and the establishment of cooperative gin associations and cottonseed oil mills are discussed.

**Sampling American cotton: Prevailing practices and some factors affecting representativeness of samples**, S. W. MARTIN and F. CLEAVES (*U. S. Dept. Agr., Bur. Agr. Econ.*, 1936, pp. 37, figs. 11).—Data were obtained by visits to 148 compresses and warehouses, 161 cotton buyers, and a large number of ginneries. The different methods used in drawing samples are described, and factors affecting the representativeness of the samples by the different methods are discussed. Extracts from State laws relating to false packing of cotton are included.

**International yearbook of agricultural statistics, 1934-35** (*Internatl. Inst. Agr. [Roma], Internatl. Yearbook Agr. Statist.*, 1934-35, pp. XXXV+896).—This volume continues the series previously noted (E. S. R., 76, p. 415), with some additional tables on the production and distribution of crops. The number of countries included in the section on trade movements has been increased, and some new series of index numbers of prices have been added.

**General crop revisions, crop years 1924-1935: Acreage, yield, and production** (*U. S. Dept. Agr., Bur. Agr. Econ., Crop Rptg. Bd.*, 1936, pp. [1]+103).—Tables show by States by years 1924-35, inclusive, the acreages, yields, and total production for grain, silage, forage, seed, etc., of corn, wheat, rye, oats, barley, flax, rice, sugar beets, sugarcane, sorghums, potatoes, sweetpotatoes, tobacco, cotton, and hays. The revisions are limited chiefly to the years 1930-35, inclusive, and are for the purpose of making the Department's estimates more consistent with enumerations of the 1935 Census of Agriculture of the Bureau of the Census.

**[Iowa farm statistics]** (*Iowa Yearbook Agr.*, 36 (1935), pp. 351-432, figs. 29).—Data collected by township assessors and tabulated by the Iowa Weather and Crop Bureau are included covering the number, size, and acreage of farms; tenure of lands; land use; numbers of tractors, automobiles, auto trucks, and radios; acreages and production of different crops; number of different kinds of livestock on farms, January 1, 1936, number of sows farrowed in the fall of 1935, and number of sows bred to farrow in the spring of 1936; etc., are presented by counties and districts in tables and maps and in a general summary table for the State. The summary tables are discussed. Other tables show for the State the acreages, production, and farm value December 1 in 1880, 1885, 1890, and 1896-1935 for corn, oats, wheat, barley, rye, flaxseed, potatoes, and tame and wild hay. Similar figures are included for alfalfa for 1900, 1905, and 1909-35 and for soybeans 1919-35.

**Missouri farm census, by counties, 1935** (*Missouri State Dept. Agr. Bul.*, 34 (1936), No. 5, pp. 20).—Data collected by the Missouri State Department of Agriculture in cooperation with the Bureau of Agricultural Economics, U. S. D. A., are presented in tables showing for the State the acreages, production, and value of different farm crops, and the value of different kinds of livestock, dairy products, and other farm products; and by counties the acreage, yield per acre, 1935 and the 5-yr. average 1929-33, the total production of different crops, and the numbers of different kinds of livestock and chickens on farms, January 1, 1936.

**Revised estimates of buckwheat acreage, yield per acre, and production, 1866-1929** (*U. S. Dept. Agr., Bur. Agr. Econ., 1936, pp. 34*).—Estimates are included for the United States by regions and by States. The revised estimates for production are somewhat higher than previous estimates for the years 1866, 1869, and 1909-29, inclusive.

## RURAL SOCIOLOGY

[**Sociological studies in Arkansas**] (*Arkansas Sta. Bul. 337 (1936), pp. 49, 50, 69, 70*).—Data are reported on health services in rural areas, by I. C. Wilson and W. H. Metzler; marketing the products of home industries, by Wilson and T. W. Douglas; and the characteristics of rural rehabilitation clients, by W. T. Wilson and Metzler.

[**Investigations in rural sociology at the Michigan Station**] (*Michigan Sta. [Bien.] Rpt. 1935-36, pp. 45-48*).—Data are given on the socializing influences of organizations in relation to rural life; nationality and population groups in Michigan and their contribution to agriculture and rural life; the standard of living of farm families in relation to types of farming, farm products, income, and community opportunities; and case studies of rural communities.

[**Rural sociology studies in Missouri**] (*Missouri Sta. Bul. 370 (1936), p. 74*).—Brief notes are given on the availability, use, and needs for additional library service in rural communities in Missouri, by E. L. Morgan and M. W. Sneed, and the rural church in Missouri, by Sneed and D. Ensminger.

**Community and neighborhood groupings in Knott County, M.** OYLER (*Kentucky Sta. Bul. 366 (1936), pp. 123-156, figs. 7*).—This is part of a comprehensive study of land utilization and related economic and social problems in Knott County in which the station cooperated with bureaus and divisions of the U. S. Department of Agriculture. The various organizations and communities and neighborhoods and their trends are described and discussed.

**Purchase and sale of meats and starchy foods by Tennessee farm families.**—A preliminary report, C. E. ALBRED and J. C. POWELL (*Tennessee Sta., Agr. Econ. and Rural Sociol. Dept. Rpt. 23 (1936), pp. 11-34, figs. 15*).—This is the fourth of this series of studies (*E. S. R., 76, p. 414*).

White farm owners of Tennessee produce 96.9 percent of the meat consumed, but 22.09 percent of the starchy foods consumed is purchased. Districts in which commercial types of farming prevail purchase the largest percentage of their vegetative foods.

**Status and migration: Notes on certain principles of migration applied to American migrants to Shanghai,** H. D. LAMSON (*Rural Sociol., 1 (1936), No. 4, pp. 472-482*).—"The purpose of this article is to examine certain 'laws' of migration in the light of one foreign community in a great Oriental seaport."

**A registration system as a source of data concerning internal migration,** C. TAEUBER (*Rural Sociol., 1 (1936), No. 4, pp. 441-451*).—The data analyzed here deal only with the city of Kiel, Germany, and are intended to illustrate the type of information available. "Short-distance migration predominated among persons moving into the city as well as persons moving out of the city. However, the least trained occupational groups (laborers and domestic servants) came from short distances more frequently than the more highly trained occupational groups, and skilled workers traveled greater distances than unskilled workers. Similarly, persons with large incomes were infrequent among the migrants into the city but came from greater distances than persons with smaller incomes. Numerically, the migration out of the city was largely a counterpart of the migration into it, and the occupational and geographical

distributions of migrants out of the city paralleled closely those of the migrants into the city."

**The influence of the AAA cotton program upon the tenant, cropper, and laborer.** F. C. FREY and T. L. SMITH (*Rural Sociol.*, 1 (1936), No. 4, pp. 483-505, figs. 5).—The AAA cotton-reduction program has greatly curtailed the annual migration of families (tenants and croppers) from one plantation or farm to another. The increased income from cotton has enabled the planter to be more generous in his advances, and the tenants and croppers know that if they leave their present location they may not be able to find another where a quota of cotton is to be had.

**Rural families on relief.** T. C. McCORMICK (*Rural Sociol.*, 1 (1936), No. 4, pp. 430-440).—"This paper is a brief summary of a survey of rural families receiving relief from State Emergency Relief Administrations, made in the winter of 1933-34 in 19 States and 47 counties by the Federal Emergency Relief Administration."

**Educational status of rural relief families in Tennessee.**—A preliminary report, C. E. ALLRED and B. D. RASKOFF ([Nashville]: *Tenn. Works Prog. Admin.*, 1936, Rpt. 22, pp. III+41, figs. 29).—This is a preliminary report on the educational status of rural people on relief in Tennessee, by age, race, tenure, sex, and residence. It presents in graphical and statistical form the educational status of members of rural households who were accepted by relief agencies. Data on which it is based were obtained from surveys in 12 representative counties conducted cooperatively by the Federal Emergency Relief Administration, the Tennessee Emergency Relief Administration, and the Tennessee Experiment Station.

Of the 2,873 heads of all relief households studied, about 17 percent have never attended any school, 54 percent have only schooling through the fourth grade, 20 percent have completed the elementary school, and less than 8 percent have any high school or college training. Of the 1,851 wives of these heads, about 15 percent have no schooling whatever, but 24 percent have advanced beyond the seventh grade, and less than 8 percent have any high school or college training.

Of all the children of relief households 46 percent of those 8 yr. of age have never attended school. From 15 to 19 yr. of age only 10 percent have completed the eighth grade, from 20 to 25 yr. 14 percent have no schooling whatever, and less than 16 percent have received training above the elementary grades. A very high percentage of the children from 6 to 15 yr. of age do not attend school although they fall within the age of compulsory attendance. On a percentage basis, more girls than boys are in school in every tenure group.

The educational attainment of negro children is low compared with whites, but a lower percentage of the younger age groups have no schooling, indicating better educational opportunities for negroes in recent years.

**Relation of education to economic and social status of relief clients in Tennessee.**—A preliminary report, C. E. ALLRED and B. D. RASKOFF ([Nashville]: *Tenn. Works Prog. Admin.*, 1937, Rpt. 24, pp. IV+37, figs. 25).—"This is a preliminary report on the relation of education of Tennessee rural relief clients to their social and economic conditions." The report, prepared in cooperation with the Tennessee Experiment Station and other agencies, is based on surveys of 2,873 relief families in 12 representative counties. Family heads with the most formal education had the largest farms and net resources, had the smallest families, and made the largest use of home production in the family living.

## AGRICULTURAL AND HOME ECONOMICS EDUCATION

**Profitable farm management and marketing for the corn-growing States**, M. H. OVERTON and L. S. ROBERTSON (*Chicago: J. B. Lippincott Co., [1936], rev. ed., pp. XII+431, figs. 210.*)—This textbook for vocational classes in high schools is based largely on the findings of the State agricultural experiment stations and is suited primarily for use in the corn-growing States. The job analysis plan of presentation is used, the material being arranged as follows: Learning the meaning and importance of farm management; comparing farm enterprises in the region; analyzing the farmer's income; balancing the farm business; selecting a farm of the right size; planning the cropping system; choosing the correct kinds and amounts of livestock; determining an efficient arrangement of fields, pastures, and lots; planning the right kinds, sizes, and locations of buildings; deciding what kinds of fences are necessary; reducing erosion and draining farm land; using farm labor efficiently; selecting the most economical kinds of farm power; equipping the farm with the right machinery; determining whether to rent or to own a farm; deciding how to rent a farm; financing the farm business; keeping practical farm accounts; adjusting the business to changing conditions; determining the nature of the marketing process; adjusting marketing procedure to kind of products; marketing through cooperation; improving marketing by individual action; marketing important crops; and marketing livestock and livestock products.

**Nutrition courses in land-grant colleges**, E. N. TODHUNTER and B. L. SPARLING (*Jour. Home Econ., 28 (1936), No. 10, pp. 668-670.*)—Examination of the catalogs of the 51 land-grant institutions in the States, Alaska, Puerto Rico, and Hawaii showed that 46 have courses in home economics. Tables show the number of institutions offering different types of courses in nutrition and dietetics with the year specified for taking the courses, hours required, and credit given, and the number of institutions requiring prerequisite courses for nutrition courses and the courses required.

**Certain bases for predicting scholastic success of freshmen in the college of agriculture**, F. M. SACAY (*Philippine Agr., 25 (1936), No. 7, pp. 589-598.*)—Scores in the Philippine mental ability test and high school grades for the 73 freshmen in the college in 1932 and the 42 in 1934 and in achievement tests in 1934 prepared by the Bureau of Education were correlated with scholastic success. The coefficients of correlation were as follows: Mental ability 0.59 in 1932 and 0.61 in 1934; high school grades, algebra 0.49 and 0.54, physics 0.46 and 0.65, geometry 0.40 and 0.67, English IV 0.36 and 0.41, general science 0.36 and 0.65, biology 0.35 and 0.52, economics 0.31 in 1932, general history 0.30 in 1932, and age -0.06 and -0.14, respectively, in the 2 yr.; and achievement (1934), algebra 0.63, physics 0.61, geometry 0.58, general science 0.53, biology 0.51, and English IV, 0.47.

## FOODS—HUMAN NUTRITION

**Foods and nutrition [at the Bureau of Home Economics]** (*U. S. Dept. Agr., Bur. Home Econ. Rpt., 1936, pp. 2-6.*)—This report (E. S. R., 74, p. 721) summarizes the work of the year in the three sections comprising the Division of Foods and Nutrition and a special study of consumer acceptance of dried skim milk.

A summary is given on the value of soybeans and the relative value of headed and nonheaded forms of cabbage and lettuce as mineral sources. Relative values, in addition to data previously noted from special reports, are also given for the ascorbic acid content of various citrus fruits, the vitamin A, B,

and G content of various nuts, and the vitamin B and G content of dried distillers' grains.

The report on food utilization includes data from studies on the influence of the fat and water content of beef on shrinkage during roasting, the cooking quality of 80 unnamed varieties of green vegetable soybeans, the waste in preparation for cooking of various common vegetables, and the effect of time and temperature of processing on the quality of canned meat, with recommendations for the home canning of various kinds of meat. Summaries are also given of studies on the relation of fertilizer composition to the blackening of potatoes on cooking, the relative heat requirements for cooking vegetables by gas and electricity, mineral losses in vegetables with different methods of cooking, consumer preferences for breads, the advantages of the Bureau method v. the jelmeter method for jelly making, and the use of sorghum sirup in food preparation.

[Studies in foods and nutrition from the Arkansas Station] (*Arkansas Sta. Bul.* 337 (1936), pp. 9-11, 46-49).—Progress reports (E. S. R., 74, p. 874) are given on studies by M. C. Kik, B. Sure, and K. S. Buchanan on the influence of vitamin B and G deficiencies on the concentration of blood and tissue enzymes; by Sure, Kik, and Buchanan on the influence of vitamin A deficiency on the concentration of blood and tissue enzymes; by Kik on the enzymatic digestion of lactalbumin v. casein in vitro; by Buchanan and Sure on the albumin-globulin ratio of the blood of the albino rat on a standardized dietary regime and on the influence of vitamin B deficiency on the albumin-globulin ratio of the blood of the albino rat; by Sure, Buchanan, and H. S. Thatcher on vitamin A and carcinogenesis; by M. E. Smith and W. L. Bleecker on the causes and prevention of spoilage of home canned vegetables; and by Smith on factors which affect the quality of canned tomatoes.

**Meats and meat food products** (*U. S. Dept. Agr., Bur. Anim. Indus. Rpt.*, 1936, p. 23).—This summarizes studies on the nutritive value of the proteins and the occurrence of the vitamin G complex in certain animal tissues.

**The effect of cooking upon the composition and serving value of beef**, J. A. CLINE and C. NESBITT (*Missouri Sta. Bul.* 370 (1936), pp. 61-63).—In this progress report tabulated data are given on the cooking time, cooking losses, and number of servings per pound of four cuts of beef—prime rib, chuck, top round, and heel-of-round—roasted to underdone, medium-done, and well-done stages, as determined by the meat thermometer. Data are also reported on the cost per serving of the different roasts calculated on the original cost of the meat, the cost of the gas consumed, and the number of servings obtainable per pound of uncooked meat, and on the range in percentages of protein, fat, moisture, and total ash in the uncooked and cooked cuts. Changes in the composition of the drippings, with increase in doneness, are noted.

**A study of seasonal variation in egg white performance**, E. A. BURKE and K. B. NILES (*U. S. Egg and Poultry Mag.*, 42 (1936), No. 9, pp. 542-547, 573, figs. 4).—Weekly scoring of a total of 202 angel food cakes made by the standard recipe from eggs obtained from the same flock on controlled feed is reported. Immediately upon removal from the refrigerator the eggs were separated and the whites were weighed and allowed to come to a temperature of 25° C. After baking, the cakes were inverted and allowed to hang in the pans overnight before being judged.

A seasonal variation in egg white performance was indicated. At the beginning of the experiment in August the cakes were fairly good in quality, gradually declining to a low level in November, with a slight rise in December and a sharp decline in January. A decided increase in quality was noticed in February and March and the quality continued to rise to the highest point in

July when the experiment was terminated. During the low periods the crusts of the cakes were gummy and difficult to cut, and the authors suggest the possibility of a correlation between this observation and humidity. During the "low" and "high" periods, the time required to beat the egg whites to the stiff stage varied. A temperature of 350° F. and a baking time of 45 min. gave the better product.

**The influence of raw and sterilized milk on growth and reproduction in rats,** H. A. and H. J. CHANNON (*Jour. Hyg. [London]*, 36 (1936), No. 2, pp. 173-181).—Two samples of commercial sterilized milk prepared by different processes were compared with the raw milk in a diet of white flour biscuit with the addition of supplements of iron, copper, and manganese salts. At the end of the experimental year the weights of the rats receiving sterilized milk were about 10 percent lower than those receiving raw milk. No difference was noted in the general health of the groups of rats. Litters could not be reared on either the raw or sterilized milk diet, but reproduction was slightly better in the animals receiving raw milk.

**The chemical composition and the nutritive value of ripe mango fruits,** A. P. C. BIJHOUWER and W. F. DONATH (*Landbouw [Buttensorg]*, 11 (1936), No. 9, pp. 370-397; *Eng. abs.*, pp. 396, 397).—Results of analyses of ripe fruits from the Alphonso tree and six mango varieties growing in Java are compared with analyses of similar fruits grown in other countries. The chemical composition of the fruit and the skin is tabulated. The literature on vitamin research in mangoes is reviewed.

**Home canning costs,** V. E. SATER (*Washington Sta. Bul.* 337 (1936), pp. 27, figs. 2).—Apples, peaches, tomatoes, corn, and green beans were canned by the open kettle and cold pack and hot pack water bath methods, as described in *Farmers' Bulletin* 1762 (E. S. R., 76, p. 419) and also following methods used at the Washington State College. In addition some peaches and tomatoes were cold packed and processed in the oven. Time and cost comparisons were made on various methods of canning and on different kinds of equipment. The fuel costs were calculated at average thermal efficiencies for ranges, using different kinds of fuel.

In general the open kettle method resulted in somewhat less time per unit quantity and lower financial cost than the other methods tested. The cold pack and hot pack methods ranked practically the same. Using the data obtained for apple canning and including the initial cost of special equipment and the average operating cost per container, it was calculated that the total cost per container was 6.36 ct. for the quart size and 5.65 ct. for the pint size glass containers and 5.63 ct. for the No. 2½ and 5.11 ct. for the No. 2 enamel-lined tin cans. Canning in tin required slightly less time and electrical energy than canning in glass. When identical processes were used gas, kerosene, and gasoline were the cheapest fuels.

**Nutritive value of diets of families of wage earners and clerical workers in North Atlantic cities, 1934-35,** H. K. STIEBELING (*U. S. Dept. Labor, Bur. Labor Statis., Mo. Labor Rev.*, 43 (1936), No. 1, pp. 14-23).—This contribution from the U. S. D. A. Bureau of Home Economics consists of an interim report on the content and nutritive value of winter diets of families living in eight North Atlantic cities, as determined from dietary records secured by the U. S. Bureau of Labor Statistics as part of the 1934-35 Works Progress Administration study of disbursements of families of wage earners and low salaried workers. From the 209 dietary records secured, 73 were selected for special analysis on the basis of the level of expense for food, including one group of 23 families spending from \$1.20 to \$1.80, 36 spending from \$2.38 to \$3, and 14 spending from \$3.57 to \$4.17 per food cost unit weekly. For 70 of these families

records were also available of the level of expenditures for all goods and services per consumption unit during the year covered by the study.

Although in general with increasing income families spent more for food, this was not true of all families, for the data showed a wide range of expenditure for food at any given economic level and a wide range in economic level of families spending similar amounts for food. Consequently some of the data are also classified by annual total expenditures per consumption unit of under \$300 (21 families), from \$300 to \$499 (32 families), and \$500 and over (17 families).

With increased expenditure for food there was some increase in the quantities purchased of each group of foods and particularly of eggs, milk, meats, fruits, and vegetables. Families spending the largest amounts for food paid about the same average prices for milk, eggs, potatoes, and dried legumes as those spending smaller amounts, but bought more expensive forms, as well as larger quantities, of foods in the other groups. The same trends, although less pronounced, were shown in the classification of the data by the level of expenditure for all goods and services.

When compared with the dietary allowances compiled by Stiebeling and Ward (E. S. R., 70, p. 416), the average food supply of the lowest expenditure groups was found to be below standard in several respects, that of the middle group to meet the allowance except possibly for calcium, and that of the highest expenditure group to include ample quantities of all nutrients. All of the diets in the highest expenditure group, over 80 percent of those in the middle group, and less than 25 percent of those in the lowest expenditure group met or exceeded the average minimum requirements. It is pointed out, however, that by applying present-day knowledge of foods and nutrition to food selection the low income groups could also raise the level of nutrition and health without necessarily increasing their food expense.

**Economy and adequacy of American diets** (U. S. Dept. Agr., Bur. Home Econ. Rpt., 1936, pp. 7, 8).—These pages include a brief description of the scope of the study of kinds and quantities of food purchased and the nutritive value of the diets of wage-earning families, a preliminary report on which is noted above, and a general summary of the analysis of the character of the diets of nonfarm families based on the available data from studies made in the United States during the past 20 yr. A more extensive presentation of the data is to be found in the paper noted below.

**Food consumption of urban and village families at different levels of food expenditure**, H. K. STIEBELING (*Jour. Home Econ.*, 29 (1937), No. 1, pp. 6-10).—All available quantitative data on the food consumption of urban and village families in the United States during 1914-33 have been used to arrive at an approximation of the levels of food consumption accompanying different levels of expenditure for food. The data include 1,020 records from individual families in six studies and two averages reported by the U. S. Bureau of Labor Statistics representing 12,000 families. The figures for food expenditures in the various studies were adjusted to the values for March to May 1935 by use of the U. S. Bureau of Labor Statistics retail food index and were classified by the principal foods or food groups in eight price groups according to yearly per capita expenditures for food, the lowest group from \$32 to \$65 and the highest from \$258 to \$290. In all cases figures refer to quantities purchased rather than actually eaten.

The trends in consumption with increased expenditures followed the same lines as noted above as to the diets of wage earners in industrial communities. There were marked increases in the total amounts of all food purchased, but more pronounced in eggs, meats, milk, butter, the succulent vegetables, and

fruits than in grain products, potatoes, dried legumes, and fats other than butter. There was a tendency to purchase more expensive forms as well as larger quantities of foods.

From dietary records secured in the spring of 1935 from families of employed wage earners whose expenditure for food was well above the median, data on the consumption of certain foods at \$2.50 to \$3.10 per person per week were tabulated for five regional groups. Less striking differences than were anticipated were found in the milk consumption in the different regions, marked regional differences in the consumption of butter and other fats, slight differences in flour and cereals, marked differences (affected by season) in the consumption of potatoes and sweetpotatoes, and also marked differences in the vegetables and fruits noted for their special nutritive values.

When the percentage distribution, according to the level of expenditure for food, of the 1,020 families studied in 1914-33 was compared with that of 2,746 families of wage earners and clerical workers studied in 1934-36, about 30 percent of the families in both studies were in the group spending from \$97 to \$129 per person per year for food. The diets of these families were thought to meet average minimum requirements, but with little margin for safety. The families in the higher groups were spending enough for food to obtain fully adequate diets with proper care in the selection and preparation of food, but only about half of the families spending as much as \$193 to \$226 per person per year had diets providing a generous margin of safety in all essentials. The frequency distribution of the families of the various groups in the two studies was very similar.

**A study of English diets by the individual method, I, II** (*Jour. Hyg. [London]*, 36 (1936), No. 3, pp. 269-309, figs. 2).—Two papers are presented.

**I. Men**, E. M. Widdowson (pp. 269-292).—The subjects were 63 healthy men of the English middle class. All food eaten was weighed and recorded for 1 week, and the amounts of calories, carbohydrate, fat, protein, calcium, phosphorus, and iron were calculated. The iron content of the diets is discussed separately (see page 722). The following values were obtained for the average daily intake: 3,067 calories, 13.1 percent derived from protein, 39.1 from fat, and 46.7 percent from carbohydrate; 97.5 g of protein, or 1.4 g per kilogram of body weight; 129 g of fat; 348 g of carbohydrate; 0.87 g of calcium; 1.61 g of total phosphorus; and 16.8 mg of total iron. The consumption of fresh milk varied from 0 to 1½ (imperial) pints daily.

From the 7-day record of the food intake of a lacto-vegetarian, the daily caloric intake was calculated to be 2,835. The total protein, fat, and carbohydrate values were similar in amounts to the average values for the 63 subjects. Due to the increased consumption of milk and cheese the calcium and phosphorus values were approximately doubled.

The food intakes of 6 unemployed men, all of whom were spending less than the British Medical Association (1933) minimum figure of 4s. 10d. per man value per week on food, showed an average daily caloric value of 2,850 and a protein value of 83 g. The consumption of fresh milk averaged 0.22 pint per day. These diets were not as a whole grossly deficient, a fact attributed to the wise spending of the housewives and, therefore, they are not deemed representative of the diets of less intelligent unemployed people.

**II. Women**, E. M. Widdowson and R. A. McCance (pp. 293-309).—Following the same procedure, the food intakes of 63 healthy women were studied and the following values were obtained for the average daily intake: 2,187 calories, 12.8 percent derived from protein, 42.7 percent from fat, and 43.6 percent from carbohydrate; 67 g of protein, or 1.1 g per kilogram of body weight; 100 g of fat; 233 g of carbohydrate; 0.63 g of calcium; 1.13 g of total phosphorus; and

11.4 mg of total iron. The average daily caloric intake was 71 percent of the average value found for the man subjects, so that the average "man value" of the women was 0.7 and not 0.8 as has been accepted. The average consumption of milk was less than  $\frac{1}{2}$  pint daily. The quantity of meat consumed averaged 60 percent of the amount eaten by the men.

One case study is reported of a woman cook who maintained apparent good health and strength, with physical energy well above the average, and remained 20 percent overweight on a diet consisting almost entirely of cakes, biscuits, puddings, and fruits.

The food intakes of the wives of the unemployed men were found to be lower in each of the dietary constituents except carbohydrate than the corresponding intakes of the middle class women. The calcium and phosphorus contents of their diets were undoubtedly nearer the minimum requirement for normal nutrition.

**Relationship of basal metabolism to dietary intake, J. A. JOHNSTON and J. W. MARONEY** (*Amer. Jour. Diseases Children*, 51 (1936), No. 5, pp. 1039-1051, figs. 6).—During a 3-yr. study undertaken to determine whether the level of basal metabolism is affected by the intake of protein or whether the total caloric intake alone is the deciding factor, 33 children, ages from 4 to 15 yr., were maintained on measured diets for periods averaging  $9\frac{1}{4}$  mo. each. The basal metabolism determinations were made by the gasometer method, and the results were compared with Boothby and Sandiford standards (*E. S. R.*, 45, p. 670). The composition of the diet was 15 percent protein, 35 fat, and 50 percent carbohydrate. The results show the expected fall in basal metabolism with a lowered food intake and the prompt return to normal with an increased intake. The subjects receiving a diet high in calories and in protein showed the maximum elevation of the basal metabolic rate. The data favor the view that the amount of protein oxidized may be an important factor in influencing the basal metabolism.

**Relation between basal metabolism and adolescent growth, C. A. LEWIS** (*Amer. Jour. Diseases Children*, 51 (1936), No. 5, pp. 1014-1038, figs. 2).—The purpose of this study was to investigate the relationship between rates of growth in normal persons, as shown by a physical trait, such as stature, and a basic measure of physiologic rate, basal metabolism. The method used was a comparison of the basal metabolism of 50 postpubertal girls, age 14-16 yr., living in an orphan asylum. More than 350 tests were made with the Benedict-Roth closed circuit system and inside soda lime container, modified to include the Benedict helmet.

The results of the study are expressed in total calories per 24 hr., calories per kilogram of body weight per 24 hr., calories per cubic centimeter per 24 hr., and calories per square meter of body surface per hour. It was noted that the oxygen consumption in total calories decreased regularly with age. When the values obtained were classified according to the number of years since the first menstruation, the age at the first menstruation, and the age of maximum increment of growth in stature, no consistent trend was shown. Compared with results of other workers on subjects of comparable age range, the girls in the orphanage had consistently lower basal metabolism rates. The literature was surveyed and evidence presented to show that the distribution of the results over a long series of determinations on subjects approaches a normal curve, therefore an average value obtained from a long series would be a more accurate expression of the basal metabolism than if the minimum value of that series were taken.

**A research in adolescence.—I, Pubescence and physical growth, H. S. DIMOCK** (*Child Devlpmt.*, 6 (1935), No. 3, pp. 177-195, figs. [18]).—This paper is

the first of a series of articles reporting findings of a research study on 200 adolescent boys. Data concerning physical measurements, personality, and social factors and their interrelationships are given. The standard test procedure, with some new technics, was employed.

The results indicate that the physical strength increases rapidly throughout the adolescent years, the most rapid development taking place during the year which follows the attainment of post-pubescence. The motor ability increases less rapidly during the adolescent years. An improvement in motor coordination was shown during the period of most rapid increase in height and weight. The cases studied did not exhibit loss of motor control, with subsequent awkwardness, when growth and height were increasing particularly rapidly.

**Basal energy metabolism and creatinine in the urine.**—I, **Observations on children**, N. B. TALBOT (*Amer. Jour. Diseases Children*, 52 (1936), No. 1, pp. 16-24, figs. 2).—The author presents a method of determining basal energy metabolism on the basis of creatinine excretion, determined by the Folin method, and indicates the accuracy of the values so obtained. The subjects were normal children. The metabolism tests were repeated until the results for two periods corresponded within 4 calories per hour. The calories per milligram of creatinine were referred to the variables age, height, weight, and surface area and to the total excretion of creatinine for 24 hr. A much closer relationship was exhibited when the basal energy per unit of protoplasmic mass was referred to the total of this mass rather than to the other variables of growth. The results indicate that the best correlation for heat production is its relation to the protoplasmic mass as measured by creatinine excretion.

**Studies on the nutrition of children** (*Michigan Sta. [Bien.] Rpt. 1935-36*, pp. 38, 39).—This progress report discusses variations found in the investigation noted previously (E. S. R., 73, p. 559), in the composition of identical diets collected at different times, and in the urinary constituents on a constant diet with the time required to reach an equilibrium.

**Growth of oriental children in San Francisco: A contrast**, M. I. PRESTON (*Amer. Jour. Diseases Children*, 51 (1936), No. 6, pp. 1324-1348, figs. 15).—Measurements were made of 740 Japanese and 391 Chinese children living in San Francisco. Questionnaires were sent to the homes for data regarding birth date and place and the home diet.

The data obtained indicate that social-economic effects in San Francisco play a part in the health, growth, and development of the Chinese children. The Chinese children were shorter in stature than the white children of San Francisco, the Japanese children of San Francisco and Los Angeles, the native children in Canton, and Cantonese children in Hawaii. The Chinese children weighed less than the Hawaiian Cantonese, and in both height and weight did not show the prepubertal vigor that was found in white and Japanese children. The statures and weights of the Japanese children in San Francisco were less than those of Japanese children in Los Angeles, but the former showed a superior bicristal diameter. The Japanese girls were superior to the boys in weight, pelvic width, stature, and amount of abdominal fat. In general the fat folds of the arm and abdomen were greater in Japanese than in Chinese children. Among the Japanese children there was a higher proportion of bone deformity, a high incidence of dental caries, and prevalence of infections of the upper respiratory tract and tonsils.

The study suggests the great possibility of error in using tables based on height and weight figures of white children as a means of predicting the weight of the oriental children.

**Voluntary food habits of normal children, C. SWEET** (*Jour. Amer. Med. Assoc.*, 107 (1936), No. 10, pp. 765-768).—The purpose of this paper is to show that healthy children will voluntarily choose an adequate diet from a well-supplied family table. The discussion is based on private practice with children living at home, and case studies are given. During a 3-week period the child is free to select his own foods, and during this period of observation his behavior is recorded by the mother and by the physician. The observer is thus able to acquire a knowledge of the food habits of the family and discover any behavior problems. Certain fundamental dietary rules are given, and an effort is made to re-educate the parents as well as train the child in proper eating habits.

**Stock diet for rats, W. THOMSON** (*Jour. Hyg. [London]*, 36 (1936), No. 1, pp. 24, 25).—The advantages are noted of the stock diet for rats being used at the Rowett Research Institute. The mixture is fed in the form of  $\frac{1}{2}$  in. cubes and consists of the following: Wheat offal (fine middlings No. 2) 19.2 percent, ground wheat 19.2, Sussex ground oats 19.2, ground barley 9.5, ground maize 9.5, meat and bone meal (45 percent protein) 9.5, dried skimmed milk 7, white fish meal (60 percent protein) 4.7, dried yeast (40 percent protein) 1.2, sodium chloride 0.5, and cod-liver oil 0.5 percent. The cubes are placed in a corner of the cage with approximately 5 g of green feed and 10 cc of separated milk per rat. By routine procedure the litters are reduced to 8 at birth and are weaned at from 21 to 23 days. At 23 days the average weight of the males is 43 g and of the females 41.5 g. The advantages of the cube method of feeding are simplicity, economy, and ease of cleaning cages, and the rats appear to enjoy holding the cubes in their "hands."

**Iron in human nutrition, E. M. WIDDOWSON and R. A. MCCANCE** (*Jour. Hyg., [London]*, 36 (1936), No. 1, pp. 13-23).—The authors give a quantitative evaluation of the total and available iron intakes of the 126 normal healthy men and women referred to on page 719, aged 18-90 yr., living on freely chosen diets, and engaged in sedentary or moderately active occupations.

The 63 women subjects showed an average daily iron intake of 11.4 mg as compared with 16.8 mg for the 63 men. Calculations show that 10.8 mg represented available iron in the men, whereas the comparative figure for the women was 7.9 mg. Some of the women substituted food such as milk and eggs, in which approximately 90 percent of the iron is in an available form, for meat which is high in total iron but relatively low in available iron.

Hemoglobin determinations were made on 42 of the men and 29 of the women subjects, using the Haldane carboxy-hemoglobinometer. The results did not show any correlation between the percentage of hemoglobin in the blood of the women and the amount of total or of available iron in the diet, but there was a slightly positive correlation between the available iron and the percentage of hemoglobin in the men subjects. It is apparent that other factors such as absorption, excretion, and menstrual loss must be considered in interpreting the findings with the women subjects. The lower percentage of hemoglobin in women's blood is either a result of low iron intake or is due to some physiological cause.

To determine whether the administration of additional iron might increase the hemoglobin percentage of normal women, 15 men and 16 women, aged 20-30 yr., were given 100 mg of iron daily in the form of ferrous sulfate or ferric ammonium citrate. Hemoglobin determinations were made weekly. The results indicate that it is difficult to raise the hemoglobin percentage of normal men even by an abnormally high iron intake. The women on the contrary showed an increased hemoglobin percentage in every case, the mean rise being over 10 percent.

**The distribution of iron in certain tissues of normal and anemic rats,** G. WAKEHAM and H. F. HALENZ (*Jour. Biol. Chem.*, 115 (1936), No. 2, pp. 429-434).—Nutritional anemia was induced in the experimental rats, the degree of anemia obtained being shown by determinations of the hemoglobin content of the blood and the erythrocyte count. The animals were divided into three groups—15 normal mature stock rats, ages from 200 to 300 days; 23 anemic rats; and 16 litter control rats, ages from 65 to 90 days. The blood samples were obtained from the blood draining into the body cavity when a lobe of the liver had been excised in the anesthetized animal. Iron determinations were made on various organs, and also on 4 kinds of washed tissue in 33 normal and 26 anemic rats.

The normal control animals showed the following iron values: Blood-free liver tissue 10.33 mg, heart muscle 6.49, kidney 5.61, and striated muscle 2.83 mg per 100 g of tissue. The comparable figures for the anemic rats were liver tissue 4.15 mg, heart muscle 4.79, kidney 3.02, and striated muscle 2.87 mg per 100 g of tissue. Wide variations in iron content of normal spleens were found, the average for both sexes being 40.4 mg per 100 g as compared with 9.42 mg in the anemic animals. The loss of hemoglobin in the blood of these two groups of animals was 77.2 percent. These results indicate that during the development of nutritional anemia the skeletal muscle loses very little iron, the heart muscle about one-fourth of its iron content, the kidney nearly half, and the liver somewhat more than half.

**Hemoglobin values in normal adults over a period of time,** W. INGERSOLL (*Jour. Lab. and Clin. Med.*, 21 (1936), No. 8, pp. 787-789, figs. 2).—Hemoglobin determinations were made weekly or oftener during a 4-mo. period on 30 young adults, following the method of Newcomer and using a Bausch and Lomb hemoglobinometer. Personal habits, age, weight, height, and the occurrence of illnesses and of menstruation were recorded for each subject.

The data indicate that normal individuals demonstrate a marked difference as to range, weekly variations, and general trend of hemoglobin values, the variations being greater in the women subjects. There does not appear to be a correlation between hemoglobin values and personal habits such as hours of sleep, slight illnesses such as colds, or menstruation. Based on the results of tests made with 6 subjects, a seasonal variation was noted. The results indicate the possibility of misinterpretation of hemoglobin values as judged from one determination.

**Further studies on the availability of copper from various sources as a supplement to iron in hemoglobin formation,** M. O. SCHULTZE, C. A. ELVEHJEM, and E. B. HAET (*Jour. Biol. Chem.*, 115 (1936), No. 2, pp. 453-457, fig. 1).—Previous studies at the Wisconsin Experiment Station (E. S. R., 73, p. 128) have been extended to include tests on the availability of copper from other animal and plant tissues and organic copper compounds carefully purified to prevent contamination with ionic copper. Milk and 0.5 mg of purified iron daily constituted the basal diet of the anemic rats to which such amounts of the various sources of copper were added to supply 0.01 mg of copper daily. Hemoglobin determinations were made weekly by the Newcomer method.

The results indicate that the copper of wheat germ, alfalfa, brewers' yeast, pork heart, pork liver, cysteine cuprous mercaptide, copper aspartate, copper citrate, copper nucleinate, and copper pyrophosphate is readily utilized by severely anemic rats to supplement iron for hemoglobin formation. In general the rate and extent of hemoglobin regeneration were about the same in all cases and corresponded closely with those obtained when 0.01 mg of copper was fed daily as copper sulfate. "Unavailability of dietary copper is apparently of little practical importance."

**A study on sulfur metabolism.—II, Comparative investigations of sulfur and protein metabolism in infants and children** [trans. title], A. BLAZZO (*Jour. Physiol. et Path. Gén.*, 34 (1936), No. 1, pp. 120–135).—This study was conducted on 9 infants aged from 3 to 5 days and 9 children aged from 3 to 14 yr. The results show that the proportion of total sulfur to the sulfur fractions of the serum is similar in children and infants. The quantity of inorganic sulfur in the serum is evaluated at from 8 to 10 mg percent, a relatively high proportion when compared with the results of studies on the sulfur content of serum in adult subjects. The sulfur found in the fecal protein represents about 10 to 12 percent of the total sulfur content.

**The effect of vitamin A deficiency on the rate of growth of the incisors of albino rats**, L. S. FRIDERICIA and S. V. GUDJÓNSSON (*K. Danske Vidensk. Selsk., Biol. Meddel.*, 13 (1936), No. 2, pp. 18, figs. 3).—Experiments were conducted on groups of adult and young rats receiving an adequate diet and of young rats receiving diets deficient in vitamin A, vitamins A and D, or the vitamin B complex. The adequate diet consisted of casein 18 percent, rice starch 54, dried autolyzed brewer's yeast 5, butterfat 15, agar 3, and McCollum salt mixture No. 185 5 percent. Oxidized lard was substituted for butterfat in the diets deficient in vitamin A and vitamins A and D. Vitamin D supplement in the form of 5 drops of irradiated ergosterol was fed to a portion of the group of young rats on the latter diet. The curative method of estimating vitamin A was followed with one group of young rats, 0.2 g of cod-liver oil being administered after 4 weeks on the vitamin A-deficient diet. Another group received varying suboptimal doses of cod-liver oil (containing about 1,500 international standard units per gram) at the levels of 0.25 mg, 0.5, and 1 mg. The adequate diet without yeast was given to the rats on the vitamin B complex-deficient test. The rate of growth of the "extrinsic" incisors was measured weekly by means of a specially constructed caliper gage.

The results indicated that the presence or absence of vitamin D in a vitamin A-free diet does not influence the rate of growth of the incisors. Almost 3 mo. of vitamin A feeding was required to bring the growth rate back to normal. The diet deficient in the vitamin B complex also depressed the rate of growth, but the effect appeared later than in vitamin A deficiency. The results suggest the possibility of using the measurement of the rate of growth of the incisors as a biological method for the quantitative estimation of vitamin A.

**Vitamin B<sub>1</sub> in human diets**, A. Z. BAKER and M. D. WRIGHT (*Roy. Soc. Med. [London]*, *Proc.*, 29 (1936), No. 9, pp. 1145–1154; *Fr., Ger. abs.*, p. 1146).—An evaluation was made of the vitamin B<sub>1</sub> content of some well-chosen adequate diets in common use, selected special diets, and sample diets associated with beriberi disease. The results of the survey showed that the vitamin B<sub>1</sub> values of the very low, moderately low, and borderline diets were 71, 90, and 264 international units, respectively. The British Medical Association diets for adults contained 212 and 440 units and over, for children of from 3 to 6 yr. of age 298 units, and from 6 to 8 yr. of age 264 units of vitamin B<sub>1</sub>. Sample high vitamin diets contained between 693 and 1,012 units of vitamin B<sub>1</sub>. Cases of beriberi were discovered in adults on diets containing 400 units or more, therefore the 200-unit level cannot be considered sufficient for adequate protection in all cases. From 200 to 300 international units may be taken as the protective level for an adult, depending on the body weight and the food consumption. During pregnancy and in digestive disorders the vitamin B<sub>1</sub> intake is particularly important. Children's diets should be relatively higher in vitamin B<sub>1</sub> than those of adults.

**Neuritis in pregnancy successfully treated with vitamin B<sub>1</sub>**, G. W. THEOBALD (*Lancet [London]*, 1936, I, No. 15, pp. 834–837).—Five pregnant patients

suffering from gestational neuritis, of which the symptoms were described as numbness, tingling, and pins and needles of the arms, hands, and legs and insomnia due to the pain, were successfully treated by dietetic measures, particularly by the administration of vitamin B<sub>1</sub> preparations. Amounts varying from 1,500 to 2,850 vitamin B<sub>1</sub> units were given daily. Two cases showed a deficiency of vitamin D in their diets, and in other cases vitamin A and calcium were given.

**The carotene content of some Indian vegetable food-stuffs, with a preliminary note on its variation due to storage, I, II, N. K. DE** (*Indian Jour. Med. Res.*, 23 (1936), No. 4, pp. 937-948).—This investigation, which is part of a survey of Indian foodstuffs, is concerned with the carotene content of about 80 green leafy vegetables, roots, fruits, legumes, and cereals.

In part 1 a modification of the spectrophotometric method of assay was employed on products purchased in the open market. The tabular figures, giving the carotene content in  $\gamma$  per gram or cubic centimeter of material, show that the green leafy vegetables are in general rich sources of carotene, as are the fruits tested in the green state. The cereals and legumes analyzed were not as rich in carotene. That photochemical activity plays a role in carotene synthesis in plants was demonstrated, leaves of cabbage being about 40 times as rich in carotene as the inner white portion. Carotene was present in much larger quantities in the skin of the orange or lime than in the juice or inside portion, the comparative figures reported being 25.7 $\gamma$  per gram of skin and 4.2 $\gamma$  per cubic centimeter of juice.

In part 2 some vegetable foodstuffs were kept in baskets or jars at various temperatures. The carotene content of some nonleafy vegetables did not change significantly during a reasonable storage period, but some of the pulses, roots, and fruits showed a steady increase of carotene content during mild or cold storage. The green leafy vegetable amaranth showed a definite lowering of carotene content after short storage.

**Factors affecting the carotene content of certain vegetable food-stuffs, N. K. DE** (*Indian Jour. Med. Res.*, 24 (1936), No. 1, pp. 201-212, figs. 3).—The author studied the variations of the carotene content in edible leafy vegetables during storage under various conditions and as a result of milling, parboiling, cooking, and sprouting.

Leafy vegetables lost carotene in storage under ordinary conditions at all temperatures, the rate of loss being greater at higher temperatures. It would appear that the rate of destruction gradually decreases as the materials become dried. Green vegetables sprinkled with water and wrapped in a wet cloth retained a high carotene content for several days. Highly milled rice was found to be completely devoid of carotene. Parboiling caused a slight loss of carotene. No loss occurred in vacuum-dried green leaves at 100° C., with comparatively rapid loss occurring when the fresh leaves were exposed to diffused sunlight. Carotene losses resulted when green leaves were preserved under water, especially when the fat solvent toluene was added to prevent mold or bacterial action. This loss could be largely prevented in the presence of carbon dioxide gas. Very slight loss of carotene occurred when formaldehyde was added to the water containing green vegetables.

Studies on the effect of cooking showed that the leafy vegetables and potatoes lost very little or no carotene on boiling, while appreciable amounts were lost from the legumes. After 45 min. of boiling rice lost 100 percent of its carotene content. A gradual loss of carotene occurred during the sprouting period.

**Absorption of carotene, W. HEYMANN** (*Amer. Jour. Diseases Children*, 51 (1936), No. 2, pp. 273-283, fig. 1).—The author studied the diminished absorption of carotene in the intestinal tracts of five children showing skin discoloration.

Using a 3-day period, he determined the carotene content of the blood serum and feces, and, assuming that carotene not recovered in the feces was absorbed, he concluded that an increased destruction of carotene within the body tissues accounted for the skin discoloration.

To study the absorption of carotene during infections, 24 healthy infants and 17 infants suffering from infections were observed. Healthy infants absorbed the carotene in oil to the extent of about 70 percent, while the infants suffering from infections showed a diminution in the rate of absorption to an average of 35 percent. As the lowered rate of absorption was observed during a 2-week period after the last day of fever, the fever alone was not the cause. In 6 healthy infants and 5 infants suffering from infections, it was found that infections did not interfere with the rate of absorption of total fat. That the carotene content of the serum rises more slowly in infants suffering from infections was demonstrated with 9 infants receiving daily doses of carotene in oil.

**The vitamin C content of Szechwan fruits and vegetables,** Y. T. CHANG and H. B. COLLIER (*Chin. Jour. Physiol.*, 10 (1936), No. 3, pp. 435-444).—The methods of Birch et al. (*E. S. R.*, 70, p. 741) and of Bessey and King (*E. S. R.*, 71, p. 137), with some modifications, were applied in the determination of the vitamin C content of about 50 samples of Szechwan fruits and vegetables. The citrus fruits gave results similar to those obtained by workers in other parts of the world, the orange, tangerine, lemon, and pomelo being of approximately equal potency. The authors report a "hairy pear" (*Actinidia chinensis*) containing an abundance of ascorbic acid (1 mg per gram). Cress, alfalfa, shepherds-purse, cauliflower, and coriander are good sources of ascorbic acid, the content ranging from 0.3 to 1.1 mg per gram of the samples.

**[Vitamin C potency of vegetables]** (*New York State Sta. Rpt.* 1936, p. 39).—This progress report (*E. S. R.*, 74, p. 887) summarizes studies on the occurrence and stability of an ascorbic acid oxidase in vegetables and on factors affecting the vitamin C content of the important commercial varieties of the common vegetables.

**Vitamin C content of vegetables.—I, Spinach,** D. K. TRESSLER, G. L. MACK, and C. G. KING (*Food Res.*, 1 (1936), No. 1, pp. 3-7).—The study reported in this contribution from the New York State Experiment Station was undertaken to obtain data on the relative importance of variety, freshness, maturity, and soil on the ascorbic acid content of spinach, as determined by the Bessey and King technic (*E. S. R.*, 71, p. 137). Biological assays were also made on two samples, the antiscorbutic values being determined by the curative type of testing. Since preliminary tests had shown that the stems are almost devoid of ascorbic acid, the experiments were made on the contents of the leaves.

The freshly cut leaves of the Prickly Winter variety had an ascorbic acid content of 0.72 mg per gram before maturity, 0.75 mg at nearly full growth, and 0.78 mg per gram after beginning to bolt. Similar values for the Hollandia variety were 0.78, 0.75, and 0.79 mg per gram, respectively. These values indicate that the ascorbic acid content of spring spinach leaves is nearly constant during the growth period. Leaves of the spinach cut as for market and kept at room temperature for 3 days lost approximately one-half of the ascorbic acid content, while duplicate samples kept at from 1° to 3° C. retained practically all of the ascorbic acid. This demonstrates the importance of refrigerating spinach soon after cutting.

The leaves of 12 varieties grown on upland soil averaged 50 percent higher in vitamin C content than those grown on muck soil and harvested the same day. The variety with the highest value on muck soil was Eskimo, 0.62 mg per gram, and on upland soil Broad Flanders, 0.89 mg per gram. Princess

Juliana gave the lowest value on both soils, 0.38 and 0.53 mg per gram on muck and upland soils, respectively.

**Biological determination of the proportion of antiscorbutic vitamin (vitamin C: ascorbic acid) in twelve of the chief varieties of apples cultivated in Sweden** [trans. title], G. F. GÜTHLIN (*K. Landtbr. Akad. Handl. och Tidskr.*, 74 (1935), No. 7, pp. 884-962, pls. 16, figs. 36; *Eng. abs.*, pp. 940-942).—Taking as the criterion of complete protection against scurvy the presence of a normal microscopic structure in the lamellae of the guinea pig's molar teeth, the author measured the vitamin C content of 12 varieties of apples by determining the lowest "micro" preventive dose against scurvy in the guinea pig. Employing the same method, the lowest micro preventive dose of pure ascorbic acid was set at  $1\frac{1}{2}$  mg resorbed ascorbic acid. The quantity of ascorbic acid resorbed in the alimentary canal per 100 g of peeled apple consumed was calculated, using this figure ( $1\frac{1}{2}$  mg). The results of the determinations, expressed in milligrams of resorbed ascorbic acid, are as follows: Bramley Seedling 22 mg, Yellow Richard 13, Belle de Boskoop 13, Ribston 8, Signe Tillisch 7, Melon apple 5, Cox Pomona 5, Grawensteiner 5, Grågylling 4, Oranie 3.5, Åkerö 3.5, and Säfstaholm 2 mg.

From these results the Bramley Seedling, Yellow Richard, and Belle de Boskoop would be suitable additions to the children's winter diet with a view to preventing a shortage of vitamin C. This study shows that Swedish apple growers can produce apples that contain at least 5 mg of ascorbic acid per 100 g of apple, and the author suggests that from the vitamin point of view the Grågylling Oranie, Åkerö, and Säfstaholm are hardly worth cultivating.

**The effect of diets and various substances on the vitamin C content of some organs of the rat**, J. L. SVIRBELY (*Amer. Jour. Physiol.*, 116 (1936), No. 2, pp. 446-455).—An investigation was made of the distribution of vitamin C in the organs of the rat to gain further information regarding the probable site of the synthesis of ascorbic acid and the nature of its precursors. Thirty-eight young albino rats of inbred strain were grouped and placed for definite time periods on test diets of varying composition: Vitamin B complex-deficient, vitamin B<sub>1</sub>-deficient, vitamin B<sub>2</sub>-deficient, and varying amounts of carbohydrate and casein. All diets were fed liberally to prevent inanition.

The results show that the rat is capable of synthesizing vitamin C regardless of the general composition of the diet. Normal vitamin C values were found in the organs of rats receiving adequate vitamin B factors in the diet. The ability of the body tissues to use ascorbic acid was increased when desiccated thyroid gland or  $\alpha$ -dinitrophenol was given. The vitamin C content of the organs was decreased when sodium fluoride was administered with the desiccated thyroid gland. The rats to which ether or cincofen was administered showed a decreased vitamin C content of the liver. Evidence is given of the role played by the small intestine in yielding primary precursors for the synthesis of vitamin C.

**Milk not potent for cevitic acid** (*Jour. Amer. Med. Assoc.*, 107 (1936), No. 10, pp. 792, 793).—This editorial shows that milk, fresh or pasteurized, cannot be considered a rich source of cevitic acid. On the basis of recent findings, if milk containing 25.9 mg cevitic acid per liter were the sole source of cevitic acid in the diet, the average adult man weighing 60 kg would need considerably more than 1 l of milk daily for optimum protection. The preschool child would require over 4 l daily and the nursing infant would need almost 2 l daily of milk for adequate protection against scurvy.

**The rôle of the thyroid in the calorogenic action of vitamin D**, H. DEUTSCH, C. I. REED, and H. C. STRUCK (*Amer. Jour. Physiol.*, 117 (1936), No. 1, pp. 1-5, fig. 1).—The basal metabolism rate was determined on two normal dogs before

thyroparathyroidectomies were performed. One dog showed a postoperative increase in the metabolic rate for 3 days, followed by a definite decline. The other dog demonstrated immediately a decrease in the metabolic rate approximately parallel with a decline in body weight. Large doses of vitamin D were administered to the two experimental animals and to two normal animals, but no marked augmentation in the metabolic rate of the experimental animals comparable to that produced in the normal animals receiving vitamin D was produced. The metabolic rate was restored approximately to the original level when the body weights of the experimental animals returned to normal. Since no explanation can be given for this effect of vitamin D, the authors are now investigating whether the thyretropic effect is due to direct action of vitamin D on the thyroid or to indirect action through the anterior lobe of the pituitary gland.

**Vitamin G concentrates as preventives against black-tongue, with parallel studies of the same concentrates in the diets of white rats, L. E. BOOHER and G. H. HANSMANN (*Amer. Jour. Physiol.*, 114 (1936), No. 2, pp. 429-435, figs. 2).**—The use of a vitamin G concentrate for the prevention of blacktongue in dogs and the growth-promoting properties of the concentrate when fed to white rats were investigated. The Goldberger diets Nos. 123 and 324, with slight modifications, were fed (*E. S. R.*, 63, p. 491). The vitamin G concentrate, which was obtained from low-lactose whey powder, contained both vitamin G (lactoflavine) and one or more factors of the vitamin B complex. This substance proved effective in the prevention or cure of blacktongue in the seven experimental dogs, 200 mg per kilogram of body weight per day being sufficient for protection. When the concentrate was fed to white rats receiving the same diets as those of the dogs, better growth was noted in the group being fed diet 324 (which has a higher protein content), supplemented by the concentrate. An inferior rate of growth was shown by those rats which were fed the diets without the addition of the concentrate.

**Reversion of cardiac enlargement in a four year old child following treatment for avitaminosis, L. RABINOWITZ and E. J. ROGERS (*New England Jour. Med.*, 215 (1936), No. 14, pp. 621-623, figs. 2).**—The authors present a case of a 4-year-old child with a cardiac enlargement who exhibited symptoms of scurvy, rickets, and possibly beriberi. After a 4-mo. period of proper feeding with adequate amounts of vitamins B, C, and D, all the symptoms of the cardiac enlargement and heart disease, as well as the avitaminosis, disappeared.

**Further studies of viosterol in the prophylaxis of rickets in premature infants, L. T. DAVIDSON, K. K. MERRITT, and S. S. CHIPMAN (*Amer. Jour. Diseases Children*, 51 (1936), No. 3, pp. 594-608, figs. 2).**—In this investigation, 27 premature infants under constant clinical supervision were given viosterol, 3,150 U. S. P. units daily from the eighth day of life, as the only source of the antirachitic substance. All infants except 2 were breast-fed and at weaning time were placed on nonirradiated evaporated milk. One infant was entirely breast-fed, and 2 received nonirradiated evaporated milk from birth throughout the experiment. The infants did not have sun baths. Roentgenograms of the forearm and wrist were made through the sixth month. The calcium and inorganic phosphorus contents of the serum were also determined monthly. Clinical data collected included observations for signs of rosary, Harrison's groove, enlarged epiphyses, changes in cranial bossae, and craniotabes.

Clinical evidences of rickets were absent in 10 infants. The remaining 17 showed considerable variation in the clinical manifestation of the mildest form of rickets. Craniotabes was found more generally in this group of infants than in any group previously reported on. Except in 2 infants, the values for calcium and inorganic phosphorus contents of the serum were at high normal

levels. This finding substantially verifies the previous claim of these authors that mild degrees of rickets may be observed clinically and by roentgenograms, although the calcium and inorganic phosphorus contents of the serum are normal. Roentgenogram examinations showed that 9 of the infants were not rachitic, but a very mild form of rickets was demonstrated in the other 18, appearing in the third month and being satisfactorily healed in the fifth to the sixth month.

**Vitamin deficiency in prescription diets of diabetics, A. SINDONI, JR.** (*Amer. Jour. Digest. Diseases and Nutr.*, 3 (1936), No. 10, pp. 759-765).—The author investigated the relationship of diet deficiency to symptomatology as observed in 85 diabetics aged from 11 to 77 yr. Approximately 48 percent of the patients were obese, and all suffered from symptoms other than diabetes. The food habits were studied during the period prior to the patients' knowledge of the onset of diabetes. Data were compiled on the foods prohibited and permitted by the family physician during the diabetic period, the duration of symptoms, insulin therapy, weight changes, blood chemistry, and complications.

During the "prediabetic" period 56 percent of the group did not drink milk, 23 excluded fruits, and 13 percent excluded vegetables from their diets. A few vegetables were eaten by 17 percent, 40 percent ate pastry, candy, or sugar, a proportionately large quantity of bread was eaten by 45 percent, 32 percent were overeaters, and all ate their meals irregularly. During the diabetic period none adhered to their prescribed diets, in which fruits, many vegetables, and cereals were prohibited and milk, eggs, meat, and fish were restricted. Special diabetic preparations such as gluten bread were prescribed for 31 percent of the patients. Insulin was administered in 42 percent of the cases.

Avitaminosis and hypovitaminosis were found in all patients. A marked correlation was noted between the vitamin-deficient diets and a rise in the incidence of diabetes, diabetic complications, or concurrent diseases. The incidence of diabetes or concurrent diseases was not related to overeating.

During a period varying from 10 days to 14 mo., any physical disturbances which might interfere with food metabolism were corrected and the patients were placed upon a diet composed of from 100 to 180 g of carbohydrate, from 60 to 80 g of protein, and from 80 to 120 g of fat. Natural, vitamin-rich foods, including vitamin D milk, were supplied, and hygienic measures such as exercise and proper body care were advocated. All the patients showed better adherence to the natural food diet, with a marked metabolic improvement and a reduction or alleviation of the symptoms other than diabetes. The obese patients returned to approximately their normal weights. Insulin administration was discontinued or reduced in 80 percent of the insulin group, and increased in the remaining 20 percent. In 1.6 percent of the group not receiving insulin previously, administrations were given to maintain blood sugar values optimum for their age. The majority of the patients showed less fluctuation in the blood sugar level. Other advantages of the dietary treatment were greater resistance to infection, more energy, and a better outlook upon life.

**Anaemia in pregnancy, J. A. BOYCOTT** (*Lancet [London]*, 1936, I, No. 21, pp. 1165, 1166-1171, 1172).—Of 222 unselected patients attending an antenatal clinic, 78 percent had greater than 80 percent hemoglobin, 22 percent less than 80 percent, and 11 percent less than 70 percent as determined with the Haldane hemoglobinometer. Detailed examination of 26 cases with hemoglobin less than 80 percent showed this group equally divided into those with normal and those with subnormal color indexes. Evidence indicated in some cases an

inconsistent increase in plasma volume causing, by the dilution of red cells and hemoglobin, an apparent anemia with normal color indexes. This condition might coexist with the true or with the hypochromic type, which is the common anemia of pregnancy and is due to an iron deficiency. The latter type responded well to adequate iron treatments except in cases with a complicating disease. Evidence further showed that factors which usually caused anemia also contributed to producing anemia in pregnancy. The data did not prove that social status, age, or parity affected the incidence of anemia.

A list of 53 references to the literature is given.

**The antianaemic principle of liver,** H. B. SREERANGACHAR and M. SREENIVASAYA (*Cur. Sci. [India]*, 4 (1936), No. 7, pp. 468-472).—This paper is a discussion of the etiology and treatment of pernicious anemia. A review is given of the work of preparing an active liver extract for treating anemia and on the studies made on the nature of the active principle in the extract. The merits of a satisfactory biochemical assay for determining the potency of liver preparations are stressed in view of the present slow method of assaying by treating human anemia.

**New outbreaks of botulism in western United States,** I. C. HALL (*Food Res.*, 1 (1936), No. 2, pp. 171-198, fig. 1).—From June 1932 to January 1936, 5 outbreaks were reported in Colorado, 4 in Montana, 3 in New Mexico, 1 in South Dakota, and 1 in Nebraska. The survey covers 13 families composed of 71 persons of whom 39 became ill and 32 died. The incidence of botulism was highest during those months when home-canned foods are most generally used. From the evidence presented only home-canned vegetables were involved, in 6 cases the toxin being present in canned cauliflower, chili, beet tops, and sweet corn. In 7 outbreaks neither toxin nor *Bacillus botulinus* could be demonstrated, but epidemiological data indicated that these cases were probably due to home-canned string beans, beets, and spinach. Two of the outbreaks were ascribed to "pressure-cooked" products. The author believes that no reliance can be placed on autoclave or pressure cookers which are not provided with separate pressure gauges and thermometers.

**The chemical composition of teeth.—I, The estimation of fluorine and the fluorine content of normal teeth,** J. H. BOWES and M. M. MURRAY (*Biochem. Jour.*, 29 (1935), No. 1, pp. 102-107).—An extensive review, with 41 references, is given of the methods used in recent years to determine small quantities of fluorine. Applying the zirconium-alizarin method to solutions of tooth material, the authors found that human enamel around London contained 0.02 percent fluorine and that the teeth of rats not on fluorine-free diets contained from 0.02 to 0.03 percent.

**Studies in the rat of susceptibility to dental caries: A review of four years of research,** T. ROSEBURY, M. KARSHAN, and G. FOLEY (*Jour. Amer. Dental Assoc.*, 22 (1935), No. 1, pp. 98-113).—In this group research, the first attempts to produce dental caries experimentally in rats were based on dietary deficiencies of calcium and vitamins D and C, on a diet high in carbohydrate, and on administration of cultures of oral human *Lactobacillus acidophilus*. This experimental procedure did not result in producing fissure lesions in rat molars identical with the caries of human beings, but such fissures were successfully produced by feeding coarsely ground brown rice or corn (in contrast to finely ground and cooked cereal), dextrin, and spinach. Fracture lesions previously identified with calcium-vitamin D deficiency were also noted in the teeth of these rats. Better calcification and improved tooth structure were obtained when the diet was corrected by adding calcium, phosphorus, and vitamin D, singly or in combination, but these food factors did not prevent tooth decay.

In explanation of the results, the writers suggest that the fissure lesions are produced by coarse particles of the cereal impacting on the molar cusps, and that poor tooth structure results from dietary deficiencies which may be factors in causing the tooth to be susceptible to decay.

## TEXTILES AND CLOTHING

**Textiles and clothing [at the Bureau of Home Economics] (*U. S. Dept. Agr., Bur. Home Econ. Rpt., 1936, pp. 9, 10*).—**This annual report of the Textiles and Clothing Division (*E. S. R., 74, p. 732*) includes summaries of a completed investigation in cooperation with the Bureau of Animal Industry on the deterioration during use of woolen blankets of known fiber and construction, and progress reports of studies on the suitability of various starches (particularly sweetpotato starch) for cotton fabric finishing.

**Strength produced in different fabrics by various starches and modified starches, M. S. FURRY (*Jour. Home Econ., 28 (1936), No. 10, pp. 687-690*).—**In studies at the U. S. D. A. Bureau of Home Economics, seven cotton fabrics of various weights and construction were sized with different starches, and the increase in their strength was measured by breaking strength determinations. To eliminate any variation due to the construction of the fabric, different concentrations of starch were used in samples of longcloth, and the results of the strength tests and elongation measurements were compared. The samples of fabrics, washed free of finishing material, were immersed in the starch pastes at 87° C. for 3 min., put through a wringer, and stretched on a wooden frame to dry.

The breaking strength determinations showed that potato, canna, and sweetpotato starches had the greatest strengthening effect, followed in order by corn, rice, dasheen, and wheat starches, and by 4 commercial cornstarches which had been partially hydrolyzed. On longcloth fabric sized with starch pastes of various concentrations the potato and canna starches gave the greatest strength, followed in order by corn, rice and dasheen, and wheat starches. Elongation measurements taken at the breaking load of the sized fabrics showed that fabrics sized with potato, corn, and canna starches stretched the least, followed in order by rice, dasheen, and wheat starches. These results demonstrate that various kinds of starches used in sizing cotton yarns or in finishing cotton fabrics produce differences in the properties of the yarns and fabrics.

**The effect of laundering upon the appearance and wearing quality of some blanket fabrics, C. JACKSON and K. CRANOR (*Amer. Dyestuff Rptr., 25 (1936), No. 16, pp. 443-449, figs. 10*).—**Samples of all wool 3-lb. single blankets were subjected to laundering tests under varying conditions. The effect of finishing was determined on a length of the unfinished blanket fabric. Before and after laundering the fibers were examined microscopically, and physical tests were made to determine tensile strength, elongation, width, weight, and thickness of the fabric, yarn count, yarn twist, length of staple, diameter of fiber, and number of fibers per yarn for warp and filling. Samples of the fabrics were washed in a vacuum type commercial washing machine, a launderometer, a hand suction dasher, a vacuum cup type, and two gyrator types of washing machines, rinsed, and dried at temperatures ranging from 85° to 120° F.

The best results in laundering an all wool blanket were obtained by washing for 3 min. in neutral soapsuds, using the hand suction dasher or the low speed vacuum cup washing machine, rinsing, and drying the fabric at room temperature. The greatest amount of shrinkage and destruction of the nap

resulted from excessive launderings in very hot water, with the application of friction. The durability and breaking strength of the blankets had been decreased in the process of napping to gain a high, thick, soft nap and to give the greatest heat-retaining property. The resulting fabric was not strong enough to withstand wear and laundering.

## HOME MANAGEMENT AND EQUIPMENT

**Household equipment** [at the Bureau of Home Economics] (*U. S. Dept. Agr., Bur. Home Econ. Rpt., 1936, pp. 11-13*).—This progress report of the Division of Household Equipment (E. S. R., 74, p. 732) includes data on fuel consumption and speed of cooking various foods both on the surface burners and in the oven of a well-insulated coal range of unusual construction, on oven temperatures and speed of heating in the oven and on a surface burner of a low-cost gas range, and on no-load performance tests of kerosene-operated and ice-cooled refrigerators of the newer types.

**Better buymanship.**—No. 20, Home heating, P. E. MOHN (*Chicago: Household Finance Corp., [1936], pp. 38, figs. 5*).—A large amount of practical information, much of it of a technical character, is presented on home heating. This relates to fuels, fuel selection, reducing fuel costs by proper construction, and the selection and installation of heating plants.

**Vacuum cleaning,** E. H. ROBERTS (*Washington Sta. Bul. 336 (1936), pp. 24, figs. 2*).—Four series of tests were made with nine electric vacuum cleaners on naturally soiled Axminster, Wilton, and velvet rugs, following practically the procedure described by Dilts (E. S. R., 72, p. 574). The cleaners were operated at a speed of approximately 1 ft. per second with the motor set at high speed. Weight determinations were made on the rugs, and the dirt collected in the bag was separated to determine the amount of nap removed.

The three types of rugs were found to be very similar in cleaning characteristics. The vacuum cleaners using suction with motor-driven brush showed an average dirt removal of approximately 84 percent during the 2-min. test period, as compared with approximately 58 percent for the cleaners using straight suction. Further tests on the effect of time in cleaning also demonstrated that the weight of dirt removed in 2 min. by the action of the former cleaner was equal to the amount removed by the latter cleaner in 4 min. The percentage of nap removal varied with the individual cleaners and type of rug. Unsatisfactory results were obtained when the tests were repeated in several homes and the performance of the test cleaners compared with those of the housewives' cleaners. The necessity of keeping the cleaner bag clean was not appreciated by most of the housewives.

The author concludes that the wearing action of a vacuum cleaner on a rug is minor when compared with the wear of normal use, and that the cleanliness of the inner surface of the bag is one of the most important factors for effective vacuum cleaning. Also the time needed for efficient cleaning appears to be a better buying criterion than the price of the vacuum cleaner.

## MISCELLANEOUS

**Report of the Secretary of Agriculture, 1936,** H. A. WALLACE (*U. S. Dept. Agr., Sec. Agr. Rpt., 1936, pp. IV+115*).—The principal findings in this report are noted elsewhere in this issue.

**Forty-eighth Annual Report [of Arkansas Station], 1936,** C. O. BRANNEN ET AL. (*Arkansas Sta. Bul. 337 (1936), pp. 73, figs. 2*).—The experimental work not previously abstracted is for the most part noted elsewhere in this issue.

**Forty-ninth Report of the Connecticut Agricultural Experiment Station, New Haven, for the year 1935**, W. L. SLATE ET AL. (*Connecticut [New Haven] Sta. Rpt. 1935*, pp. [903], pls. 8, figs. 180).—In addition to the usual administrative data, this report contains reprints of Bulletins 377–389, noted previously or elsewhere in this issue, and of the following circulars: Nos. 107, Windsor-A, a New Sweet Pepper, by L. C. Curtis (pp. 1–7); 108, Connecticut Laws Concerning Plant Pests, Diseases of Bees, and Mosquito Elimination, by W. E. Britton (pp. 9–16); 109, Control of the Mexican Bean Beetle in Connecticut, by N. Turner and R. B. Friend (pp. 17–24); 110, Requirements for Tree Workers in Connecticut (pp. 25–36); 111, Control of the White Apple Leafhopper, by P. Garman and J. F. Townsend (pp. 37–47); 112, Sweet Corn Inbreds, by W. R. Singleton and D. F. Jones (pp. 49–58); 113, Lawn Management, by M. F. Morgan, E. M. Stoddard, and R. B. Friend (pp. 61–70); 114, Insecticides to Control the European Corn Borer, by N. Turner (pp. 73–76); 115, Law and Regulations Concerning the Inspection and Shipment of Nursery Stock in Connecticut, by W. E. Britton (pp. 77–84); and 116, Regulations Concerning Transportation of Nursery Stock in the United States and Canada, compiled by W. E. Britton (pp. 85–110). A tribute to the late Dr. L. B. Mendel (*E. S. R.*, 74, p. 893) is also included.

**Annual report of the director [of the Delaware Station] for the fiscal year ending June 30, 1935**, C. A. McCUE ET AL. (*Delaware Sta. Bul. 203 (1936)*, pp. 42).—The experimental work not previously referred to is for the most part noted elsewhere in this issue.

**Report of the Michigan Agricultural Experiment Station for the two years ended June 30, 1936**, V. R. GARDNER (*Michigan Sta. [Bien.] Rpt. 1935–36*, pp. 61).—The experimental work not previously reported is for the most part noted elsewhere in this issue.

**Work of the [Missouri] Agricultural Experiment Station, [1935]**, F. B. MUMFORD, S. B. SHIRKY, ET AL. (*Missouri Sta. Bul. 370 (1936)*, pp. 100, fig. 1).—The experimental work not previously abstracted is for the most part noted elsewhere in this issue.

**Service to Montana's livestock industry: The Forty-second Annual Report of the Montana Agricultural Experiment Station, [1935]**, F. B. LINFIELD (*Montana Sta. Rpt. 1935*, pp. 60, figs. 22).—In addition to the usual administrative data and a meteorological report for 1935 (pp. 54, 55), this report is devoted mainly to a discussion of the station work relating to livestock. The experimental work not previously referred to is for the most part noted elsewhere in this issue.

**Fifty-fifth Annual Report of the New York State Agricultural Experiment Station, [1936]**, U. P. HEDRICK (*New York State Sta. Rpt. 1936*, pp. 114).—The experimental work not previously referred to is for the most part noted elsewhere in this issue. Meteorological records at the station, 1883 to 1935, inclusive, are appended (pp. 103–114).

## NOTES

---

**Arizona University and Station.**—Six greenhouse units, together with a head house, are being completed for the use of the various departments in the College of Agriculture.

A. A. Nichol, assistant professor of range ecology and acting head of the department, has been granted a year's leave of absence to accept a Rocky Mountain sheep fellowship provided by the National Association of Audubon Societies.

**Kansas Station.**—New appointments include the following assistants: J. C. Frazier in plant physiology to devote major attention to a study of the physiology of the bindweed plant, Dr. Ralph M. Conrad in chemistry to study the proteins of the egg in cooperation with the department of poultry husbandry, and Catherine Mitchell in animal husbandry to assist with the compilation of records.

**Louisiana University and Station.**—Dr. A. H. Groth, assistant professor of physiology and assistant pathologist with the Colorado College and Station, has been appointed assistant professor of animal pathology, effective February 1. For the present he will devote his entire time to research, but beginning July 1 it will be about equally divided between research and teaching.

**Minnesota University and Station.**—A State potato improvement association has been formed with an initial membership of 120 and headquarters at University Farm. Its purpose is to improve the potato crop through the spread of information to growers, selection and breeding for increased yield and better quality, aiding in the testing, introduction, and distribution of new varieties, and serving as a clearing house for ideas on problems affecting the industry.

Julius Romness, since 1925 instructor and assistant professor of agricultural physics and assistant in the station, died January 22. He had given special attention to problems in rural electrification.

**Missouri Station.**—A new greenhouse has been built as a Works Progress Administration project at a cost of \$14,000. About 3,000 sq. ft. of space will thereby become available for investigations in plant pathology, plant physiology, and general botany. A two-story storage unit has also been built at a cost of \$1,500, and will be used for the soils and crops departments.

The station has been designated to receive the assets of a foundation recently established by J. C. Penney, a native of Missouri. Under the provisions, the Foremost Guernsey Association, Incorporated, has been endowed with approximately \$300,000, in addition to 1,000 acres of land near Hopewell Junction, N. Y., 352 head of Guernseys, and buildings and equipment. The association is to engage in a long-range program of practical and scientific research intended to advance dairying practices and the development of Guernseys. Before or at the termination of a 60-year period, however, all assets will be turned over to the station.

**Nebraska University and Station.**—J. C. Russel resigned February 1 as professor of agronomy in charge of soil research in the station, but is con-

tinuing as assistant regional director for rural resettlement with the U. S. Resettlement Administration.

**North Dakota Station.**—Dorothy G. Berrigan, assistant in home economics, resigned April 1.

**Pennsylvania College and Station.**—The buildings of the Regional Laboratory for Pasture Research (E. S. R., 75, p. 3) are nearing completion. It is planned to dedicate the laboratory May 4, when representatives of the Department and of the experiment stations of the Northeastern States will be present to discuss the future program.

Research in the interest of the fruit growing industry has been given an impetus by an enlargement of the work of the Arendtsville Field Laboratory in Adams County. Harold J. Miller has been appointed plant pathologist; L. C. Marston, Jr., of the University of Tennessee, entomologist; and Charles O. Dunbar of the Connecticut College, horticulturist. S. W. Frost, entomologist of the laboratory since its inception in 1918, has been transferred to State College.

The first unit of a new greenhouse range to be used for research is under construction.

A research forest of several thousand acres, 15 miles from the college, has been made available through the cooperation of the U. S. Resettlement Administration. A similar area adjacent to it has been provided for the Allegheny Forest Experiment Station.

Dr. S. W. Fletcher has resigned as head of the department of horticulture to devote full time to his duties as director of research. Warren B. Mack, professor of vegetable gardening, has been appointed head of the department.

Dr. J. E. Hunter, associate professor of agricultural and biological chemistry, has resigned to accept a commercial position. Dr. R. H. Sudds, assistant professor of pomology, has resigned to become assistant professor of pomology in the West Virginia University.

Edward S. Erb, associate professor in charge of agricultural analyses and meteorologist, died February 19 at the age of 59 years. A native of Pennsylvania, he was graduated from the college in 1901, received the M. S. degree in 1908, and has been associated with the chemical work since 1909.

**Puerto Rico College Station.**—Director F. A. López Domínguez has been given leave of absence for a year to assist in the work of the Puerto Rico Rehabilitation Administration. Dr. Melville T. Cook, phytopathologist, has been appointed acting director from March 3 to June 30.

**Washington Station.**—Harley D. Jacquot, formerly assistant at the Adams Substation and more recently with the U. S. Resettlement Administration, has been appointed acting superintendent of the substation.

**Wisconsin University.**—The Alumni Research Foundation (E. S. R., 63, p. 106) has appropriated funds aggregating \$163,000 for the coming year to be used on both old and new research projects under the direction of faculty members. About 80 projects are now under way, selected and approved by the university research committee. The new allotment is an increase of \$20,500, and is subdivided into \$100,000 for grants-in-aid for equipment and maintenance for over 100 graduate research workers, \$17,000 for faculty summer vacation research, \$20,000 for special fellowships and scholarships, \$7,500 for continuation of several post-doctorate fellowships, \$10,500 as a printing fund under a university press to be established, and \$8,000 for the continuation of work now under way on game management and land waste problems.

**Necrology.**—Dr. Oliver L. Fassig, widely known for his contributions to American climatology, died December 6, 1936, at the age of 76 years. A native of Ohio, he was graduated from the Ohio State University in 1882, and in 1899 was the first to receive the Ph. D. degree in meteorology from the Johns

Hopkins University. He became associated with the Weather Bureau in 1883, working for many years in Puerto Rico, and had nearly completed an elaborate monograph on the climate of that island. At the time of his retirement in 1932, he was Chief of the Climatological Division of the Weather Bureau. He was a voluminous writer, one of his early contributions being an account of the 1896 convention of German experiment stations (E. S. R., 8, p. 447).

Harry N. Vinall, senior agronomist in the U. S. D. A. Bureau of Plant Industry, died February 22 at the age of 57 years. A native of Iowa, he was graduated from the Kansas College in 1903 and received the M. S. A. degree from Cornell University in 1912. He had been associated with the forage crops work of the Department since 1909, specializing in pasture grasses and sorghums.

George L. Bidwell, chemist in charge of the cereal section of the U. S. D. A. Food and Drug Administration, died February 22. Born in New Hampshire in 1880, he was graduated from Tufts College in 1905 and served as instructor in Rhode Island College in 1906-7. He had been associated with the Department since 1908. He was active for many years in the Association of Official Agricultural Chemists and a member of the executive committee of the Association of American Feed Control Officials, Incorporated.

*New Journals.*—*The Palestine Journal of Botany and Horticultural Science* is being published at approximately 4-mo. intervals at Rehovoth, with W. Junk, Scheveningsche Weg 74, 's Gravenhage (The Hague), as sole agent for foreign countries. The initial number contains the following original articles: In English, The Present State of Botanical, Horticultural, and Sylvicultural Research in Palestine, With a Bibliography of Palestinian Botany (pp. 8-21), and Critical Remarks on the Value of Lloyd's Alcohol Fixation Method for Measuring Stomatal Aperture (pp. 43-47), both by the editor, H. R. Oppenheimer; On the Influence of Various Liquid Fixatives on Stomatal Behaviour, by M. Nadel (pp. 22-42); *Cuscuta monogyna* Vahl, by E. Hareubeny (pp. 43-50); and The Application of Respiration Poisons in the Cure and Prophylactic Treatment of the Living Tree, by R. Falck (pp. 70-92); and, in German, Hugo de Vries as Plant Physiologist, by H. R. Oppenheimer (pp. 51-69).

*Annales Agricoles de l'Afrique Occidentale* is being published quarterly, with business offices at 11 Rue Victor-Cousin, Paris, and editorial headquarters at Bingerville, Ivory Coast, Africa. Its aim is to deal with questions pertaining to the agriculture, silviculture, animal husbandry, and economics of west Africa, which is said to be without a periodical "exclusively devoted to agricultural questions." In addition to brief notes and numerous abstracts, the initial number contains the following articles: The Principal Nematodes, Myriapods, and Insects Parasitic on Cultivated Coffee in French West Africa, by A. Mallamaire (pp. 1-45); The Fruit Problem in West Africa, by P. Mulheim (pp. 46-67); Volunteer Coffee in the "Eucoffaeae" Section, by R. Portères (pp. 68-91); The Rust of Coffee in Cameroun (Camerouns), by L. Roger (pp. 92-98); and The Spotting of Coffee Grains, by A. Fritz (pp. 99-109).

*Revista de Agricultura* is being published monthly by the Provincial Government of Habana, Cuba. The initial number consists largely of brief articles contributed by members of the staff of the University of Habana and others on various phases of Cuban agriculture.

*Revista Algodoeira* is being published monthly as the official organ of the Syndicate of Cotton Industries of Pernambuco, Brazil. The initial number contains several articles dealing with the history and development of cotton growing in Brazil and related topics.

# EXPERIMENT STATION RECORD

VOL. 76

JUNE 1937

No. 6

---

## SOME RECENT DEVELOPMENTS IN DOCUMENTATION

Documentation, according to the latest edition of Webster's New International Dictionary, is the "act of furnishing with documents." Of late the term has been applied with increasing frequency to the service of making available to would-be users copies of publications (or reproductions thereof) and other bibliographical material. In this latter sense, it has direct significance for research workers, educators, and extension workers in agriculture and home economics, and at least two recent developments in the field are of considerable general interest.

In this country the most important occurrence has been the organization of American Documentation Institute, Inc. This institute, set up as a Delaware corporation for educational, literary, and scientific purposes, resulted from a meeting in Washington, D. C., on March 13, 1937, attended by representatives of national councils, societies, libraries, and other groups. Among its aims, as set forth in the certificate of incorporation, are the following: "(a) To assemble, classify, reproduce, and distribute documents of all sorts in all fields of human activity; (b) to conduct, operate, and furnish services for the collection, preparation, distribution, and sale of information, articles, monographs, references, bibliography, compilations, illustrations, and reviews to individuals, to newspapers, periodicals, journals, magazines, to societies, libraries, educational institutions, archives, museums, research organizations, and to governments; (c) to copy and duplicate by photography, microphotography, lithography, blueprinting, printing, mimeographing, and other processes of reproduction and to reproduce, project, and transmit by electrical, photoelectric, radio, television, and other means books, journals, manuscripts, illustrations, and other materials in libraries, institutions, organizations, business offices, archives, museums, laboratories, research centers; \* \* \* (e) to sponsor instigate, and conduct developments of all phases of documentation and reproduction of research materials in the fields of the physical,

natural, social, economic, historical, and other sciences, the humanities, and the general sphere of libraries and information services; \* \* \* (g) to cooperate with journals, libraries, institutions, societies in the reproduction, publishing, preservation, and distribution of any documentary material, articles, manuscripts, and other written, illustrative, or photographic material."

The institute is thus very broadly chartered, but its immediate objective is "to develop and apply the new technic of microphotography to library, scholarly, scientific, and other material." The formation of an organization for this purpose has been in contemplation since the undertaking of documentation activities by a division of Science Service in 1935. Temporarily these activities have been implemented with grants from the Chemical Foundation and carried on with the cooperation of the U. S. Department of Agriculture Library, the Naval Medical School, the Bureau of the Census, the Works Progress Administration, the Library of Congress, and other agencies. The principal channel of operation has been through Bibliofilm Service, conducted by Science Service in cooperation with the Department of Agriculture Library, together with some auxiliary publication of material through microfilms in cooperation with leading scholarly and scientific journals.

Bibliofilm service was instituted on an experimental basis by the Department of Agriculture Library late in 1934. It was hoped to decrease interlibrary loans of publications by supplying directly to individuals film copies of scientific articles and also to extend the use of the library to isolated workers. In the beginning satisfactory projectors for reading the films were not available at a reasonable price, but nevertheless a favorable response was made to the new venture. In the fiscal year 1935 1,078 film copies were supplied, and in 1936 2,206 film copies.

On January 1, 1936, the business management of the service, the routine photography, and the experimentation in developing mechanism were taken over by Science Service under a cooperative agreement, the Library continuing to supply space, the publications to be filmed, and the bibliographical work connected with orders. Ultimately much success was obtained in devising microfilm viewers and other accessories. Both microfilm and photocopies for reading without optical aid were made available at nominal cost.

A second function attempted by Science Service—that of original issue, under what is termed auxiliary publication—was intended, according to its sponsors, "to break the log jam that now dams scientific publication in many fields, making it possible to put into the realm of accessible scientific literature material of all sorts that can not now be printed because of economic factors." Under its provisions, editors of participating journals or institutions deposit

typescripts of those papers or portions of papers they cannot publish promptly or completely. Microphotographs are then made, from which copies can be prepared as desired. Knowledge of the availability of the document is obtained chiefly by abstracts or other notices in scientific journals. This service has been found to have special possibilities in connection with theses and dissertations for which a limited circulation is reasonably adequate.

The documentation activities of Science Service are now to be transferred to the new institute. This is constituted as a distinct and independent entity, and its policies are still in the making. Presumably, however, the projects referred to will be maintained and developed, and additional ones of similar scope may be fostered as opportunity offers. If so, much useful service should be forthcoming. Among the advantages which should result from a permanent and centralized agency are a more standardized procedure and an increased inter-institutional cooperation.

Preparations are also being made for arousing interest and rendering assistance along much the same lines through a World Congress of Universal Documentation, projected "to promote the collective study and discussion of all questions relating to documentation." This Congress is to be held in Paris from August 16 to 21, 1937, under the auspices of an International Committee of Documentation. The American member of this committee is Mr. Watson Davis of Science Service.

A prospectus of the Congress calls attention to the fact, probably little known in this country, that an International Institute of Documentation has already been in existence for 40 years. Such agencies as the International Federation of Librarians Associations, the International Labour Office, the International Institute of Agriculture, and the International Office of Chemistry have also been giving it considerable attention. Nevertheless, as the prospectus states, "coordination, cooperation, joint and unified proceedings are still slow, whereas research workers demand the maximum efficiency in what is to be used by all as an intellectual tool." If the Congress is successful in bringing together representatives of the many interests which might benefit from an international organization of documentation—authors, societies, institutions, publishers, book sellers, libraries, and individual users—an interchange of views may result which can hardly fail to be stimulating as well as informative.

## RECENT WORK IN AGRICULTURAL SCIENCE

### AGRICULTURAL AND BIOLOGICAL CHEMISTRY

[Technological chemistry and bacteriology at the California Station] (*California Sta. [Bien.] Rpt. 1935-36, pp. 121-126*).—This report touches briefly upon the processing of fruit, fruit juices, grape varieties for high-quality wines, refrigeration of wine, wine spoilage, important factors in wine making, utilizing winery wastes, olive processing, freezing storage of vegetables, and beeswax.

[Chemical studies by the Hawaii Station] (*Hawaii Sta. Rpt. 1936, pp. 50-55, 57, 58, fig. 1*).—These are described under the headings the sterols of tropical oils, by L. N. Bilger; iodine content of Hawaiian soils and rocks, by E. M. Bilger; and taro processing, by G. J. Ley, J. H. Payne, and [G. H.] Akau.

Quantitative investigations of amino acids and peptides, I, II, M. S. DUNN and A. LOSHAKOFF (*Jour. Biol. Chem., 113 (1936), Nos. 2, pp. 359-369, fig. 1; 3, pp. 691-694*).—These contributions are from the University of California at Los Angeles.

I. *Quarantine formol titration*.—The precision attainable in the analysis of amino acids and peptides was found to be  $\pm 0.1$  percent. The method was found to have an inherent accuracy of  $\pm 0.1$  percent. The probable effects of different types of impurities on the accuracy of the method are discussed.

The gain in accuracy over that attainable by procedures hitherto available is indicated in the statement that, in what the authors found to be one of the most satisfactory of the indicator titration methods, "under optimum conditions of indicator color and acetone concentration the average experimental error was approximately 0.5 percent."

II. *Apparent acid dissociation constants in aqueous formaldehyde solution*.—The apparent acid dissociation constants of a series of amino acids and peptides were determined for the following amino acids in 9 percent formaldehyde: *dl*-alanine, glycine, *dl*-norleucine, *dl*-phenylalanine, *dl*-serine, and *dl*-valine. Like data for seven dipeptides and one tripeptide were also obtained.

The isolation of a fourth crystallizable jack bean globulin through the digestion of canavalin with trypsin, J. B. SUMNER and S. F. HOWELL (*Jour. Biol. Chem., 113 (1936), No. 3, pp. 607-610, figs. 2*).—Though they had been able to obtain three jackbean globulins (concanavalin A, concanavalin B, and an urease) in a crystalline condition, the authors of this contribution from Cornell University had not obtained unaltered canavalin in a crystalline form when crystals of a globulin previously unknown were found to have been deposited from a canavalin preparation contaminated by bacteria. They, discovered, however, that "if one adds 1 volume of 1 percent Fairchild's trypsin to 1 volume of 6 percent canavalin at pH 6.5 and maintains the solution at 37° [C.], crystals of the new globulin will begin to separate out after 1 or 2 hours. After incubation overnight the process will be finished. The yield of crystals is increased by cooling the warm solution. . . ."

"The material gives a strong test for unoxidized sulfur and for tyrosine but gives no Hopkins and Cole test, whereas the original canavalin contains 0.2 percent tryptophan. Carbohydrate is absent. The isoelectric point of the crystals in 0.1 N acetate buffer is at pH 4.8, as determined by cataphoresis. The globulin is denatured incompletely by boiling, or by contact with 0.1 N sodium hydroxide. It is resistant to 0.1 N hydrochloric acid. It is hardly affected by incubation overnight at 37° with either pepsin or trypsin.

"The most interesting property of the new globulin is its solubility in distilled water at pH 6.5 and its insolubility in 0.2 to 1 percent sodium chloride. If one dialyzes the globulin until it is salt free, the crystals slowly dissolve. The solution thus formed will give a crystalline precipitate if one adds a small amount of sodium chloride or calcium chloride solution. Upon adding an excess of 5 percent salt solution the crystals dissolve. The globulin behaves in a similar manner on the acid side of the isoelectric point but not at the isoelectric point itself.

"It is not yet possible to say whether the new globulin exists as such in the canavalin fraction or whether it is formed de novo by the proteolysis of canavalin. It would appear reasonable that the action of trypsin is to digest away some protein which prevents the new globulin from crystallizing."

**The influence of method of preparation and of cations on the isoelectric point of ovalbumin.** E. R. B. SMITH (*Jour. Biol. Chem.*, 113 (1936), No. 2, pp. 473-478, figs. 2).—According to the author, the nature of the crystallizing salt used in the preparation of egg albumin shows very little or no effect on the isoelectric point of the protein; the pH of the isoelectric point is linearly related to the ionic strength; the influence of each cation is roughly proportional to its valence, but each ion has a specific effect; and extrapolation to 0 ionic strength of the apparent values for the isoelectric point of ovalbumin, cataphoretically determined, in acetate buffers of a number of cations, gives an isoelectric point of  $pI\ 4.86 \pm 0.02$ .

**An immunological study of the reduction of disulfide groups in proteins.** D. BLUMENTHAL (*Jour. Biol. Chem.*, 113 (1936), No. 2, pp. 433-437).—The author investigated the immunological effect of reduction and regeneration of disulfide groups. Horse serum albumin was chosen for this purpose because of its high content of cystine, none of which exists in the sulfhydryl form, and because some of its immunological relations have been worked out on a quantitative basis. Similar experiments were carried out with crystallized egg albumin. "This protein, in contrast to serum albumin, gives practically no color on treatment with cyanide and nitroprusside, and therefore appears to be incapable of yielding normally functioning sulfhydryl groups."

The reduced serum albumin was obtained by treating a solution of crystalline serum albumin with thioglycolic acid at pH 8. Crystalline egg albumin was treated with a 300-fold excess of cysteine at pH 8 in the presence of a trace of ferric chloride. Reoxidation was effected in both cases by means of hydrogen peroxide.

In the case of the serum albumin "the effect upon the precipitin reaction of reduction and reoxidation reveals itself in two distinct ways. Firstly, the absolute amount of nitrogen precipitated is definitely less in the cross reaction than in the homologous precipitin determination. It may be pointed out that qualitative precipitin tests would scarcely have yielded this information. Secondly, the usual inhibition of precipitation by excess of test antigen is not found; on the contrary, there is a slight but steady increase of precipitate as the excess of antigen is increased." No notable differences in immunological behavior between the native, "reduced", and "reoxidized" forms of egg albumin could be detected. "With egg albumin, the failure of treatment with cysteine to

induce immunological differences correlates with the failure of the cyanide-nitroprusside test for sulfhydryl; on the other hand, the difference observed with heat-denatured egg preparations correlates with the appearance of sulfhydryl groups on coagulation by heat."

"These results indicate either that the S—S and —SH groups may be among the specific chemical groups involved in antigen-antibody combination, or that the reduction of the S—S linkage may split the antigen molecule into units which are too small to give the same immunological response as the original protein."

**Lactoflavin, a possible contaminant of vitamin-free diets**, G. C. SUPPLEE, G. E. FLANIGAN, Z. M. HANFORD, and S. ANSBACHER (*Jour. Biol. Chem.*, 113 (1936), No. 3, pp. 787-792, pl. 1).—The authors express the belief that lactoflavin "is a contaminant of crude or commercial caseins and even of certain 'purified' vitamin-free caseins." Extraction of dry commercial caseins with weak acetic acid and alcohol for extended periods fails to eliminate all of the contaminating lactoflavin. Its presence in the 'purified' product may be readily revealed by examination in 'black light' under proper conditions.

"A process of preparing vitamin-free casein, involving a six-step elution treatment with weak sodium chloride solution at the isoelectric point of the casein, results in a product entirely free from lactoflavin."

The relative lactoflavin contents of various caseins and water-soluble vitamin concentrates were correlated with their growth-promoting properties.

**The hydrolysis of starch by hydrogen peroxide and ferrous sulfate**, W. R. BROWN (*Jour. Biol. Chem.*, 113 (1936), No. 2, pp. 417-425).—It has been found that the action of hydrogen peroxide and ferrous sulfate upon starch is a hydrolysis, producing, in the course of the reaction dextrans, sugars of high molecular weight, and simple sugars. "The reaction is analogous to that produced by amylase, differing only in the fact that the simple sugars produced are further hydrolyzed and oxidized to acids and aldehydes. The reaction appears to be a true catalysis, the iron acting to transfer energy from the peroxide break-down to the starch molecule, thus raising the energy level of the starch and causing it to be reactive."

**Technical aspects of emulsions** (London: A. Harvey, 1935, pp. [5]+150, figs. [21]).—Several of the following chapters bear more or less directly upon phases of agricultural technology:

Foreword, by F. G. Donnan; On the Mechanism of Emulsification, by H. Freundlich; The Use of Highly Dispersed Emulsions in the Treatment of Toxaemic Conditions, by V. G. Walsh and A. C. Frazer; Emulsions in the Patent Literature, by W. Clayton; The Design of Emulsifying Machines, by R. I. Johnson; Effect of the Mode of Preparation on the Dispersion of Soap-Stabilised Emulsions, by R. Dorey; Problems Connected With the Preparation and Application of Emulsions Used in Agricultural Spraying, by R. M. Woodman; Some Observations on a Typical Food Emulsion, by J. W. Corran; Emulsions and Emulsification in the Wool Textile Industry, by J. B. Speakman and N. H. Chamberlain; The Stability of Emulsions in Thin Films, by L. A. Jordan; Emulsions in the Leather Industry, by W. R. Atkin and F. C. Thompson; Rubber Latex, by H. P. and W. H. Stevens; and Some Physical Properties of Dispersions of Asphaltic Bitumen, by L. G. Gabriel.

**The chemistry of the hormones**, B. HARROW and C. P. SHEERWIN (Baltimore: Williams & Wilkins Co., 1934, pp. VII+227).—The authors give it as their purpose to produce "a practical book—a book of use to the laboratory worker who wishes to prepare active hormone fractions, or to isolate a chemically pure hormone; and of use to the student who wants a connected account dealing with the chemical characteristics of the hormones, insofar as they

are known at present." The chapter headings are the thyroid hormone, the parathyroid hormone, insulin, the pituitary hormones, the adrenal hormones, the male hormone, the female hormones, secretin, and plant hormones. The book contains also an index of authors and a subject index.

**The preparation of a concentrate of vitamins B<sub>1</sub> and B<sub>2</sub> from brewers' yeast.** M. I. SMITH and A. SEIDELL (*Pub. Health Rpts. [U. S.], 51 (1936), No. 22, pp. 685-688*).—In continuation of attempts to concentrate and isolate antineuritic vitamin B<sub>1</sub> (E. S. R., 71, p. 298), a method has been developed for the further concentration of both vitamin B<sub>1</sub> and B<sub>2</sub> fractions in the extract derived by eluting the vitamins from the fuller's earth adsorbate. The new concentrates are considered of special value in nutritional investigations requiring rigorous control of the nitrogenous constituents of the synthetic diet, for they contain practically the same amount of nitrogen as in dried brewers' yeast with a vitamin B<sub>1</sub> potency of from 60 to 500 and a B<sub>2</sub> potency of from 70 to 175 times that of dried yeast.

In the method as described the active material was extracted from the fuller's earth adsorbate by suspending the adsorbate in water, adding sodium hydroxide to bring the solution to about 0.4 N, agitating, and acidifying to pH 4.5. The aqueous solution was concentrated by vacuum distillation, the brown precipitate formed containing most of the vitamin B<sub>2</sub> and much of the vitamin B<sub>1</sub>. This was further purified by extraction with alkaline methyl alcohol in which the greater part of the inert material was insoluble. In determining the activity of the concentrates for vitamins B<sub>1</sub> and B<sub>2</sub>, the tests for B<sub>1</sub> were based on determinations of the minimum amount of concentrate required to bring about a remission in polyneuritic rats. The B<sub>2</sub> activity was measured in terms of weight increment per day when fed for a period of 10 days to rats on a basal diet adequately supplemented with intravenous injections of the crystalline antineuritic vitamin.

The purified preparation contained from 2,000 to 2,500 international units of vitamin B<sub>1</sub> per gram and from 325 to 875 B<sub>2</sub> units per gram, as compared with 6 units of vitamin B<sub>1</sub> contained in 1 g of dried brewers' yeast. In a series of experiments, rats having dermatitis produced by existing on a diet devoid of the vitamin B complex and supplemented with crystalline vitamin B<sub>1</sub> were cured by administration of this preparation.

**Precipitation and color reaction for ascorbic acid: Specificity of acidified sodium selenite solution.** V. E. LEVINE (*Soc. Expt. Biol. and Med. Proc., 55 (1936), No. 2, pp. 231-235*).—Reducing tests are reported for certain compounds of selenium with ascorbic acid and other organic compounds of biological significance which have reducing properties.

Ascorbic acid was found to differ from all of the other substances tested by having the specific property of reducing an acidified sodium selenite reagent in the cold, with the formation of a brick-red color characteristic of free selenium. This color is also imparted in the cold to plant and animal tissues containing ascorbic acid when they are sprinkled with an acidified selenite reagent prepared by adding 1 part of concentrated hydrochloric acid to 5 parts of a 2-percent selenite solution.

**The constitution of calciferol (vitamin-D): A review and a suggestion.** O. ROSENHEIM and H. KING (*Jour. Soc. Chem. Indus., Chem. and Indus., 54 (1935), No. 30, pp. 699-701*).—The authors discuss the bases of probability of various proposed formulas, concluding that "the assumption of the presence in calciferol of a tricyclic ring system, embodying a combination of a 10-, 6-, and 5-membered ring, to which is joined a 9-membered side chain, offers such a unique and specific arrangement of carbon atoms that it would not be surprising to find it associated with the equally specific antirachitic activity of

calciferol. The formulas based on this ring system are in agreement with the results of unimolecular surface film measurements and fulfill the demands of X-ray crystallography, a point in their favor without necessarily proving their correctness."

**The molecular shape of calciferol and related substances**, J. D. BERNAL and D. CROWFOOT (*Jour. Soc. Chem. Indus., Chem. and Indus.*, 54 (1935), No. 30, pp. 701, 702).—The authors compare the formulas suggested in the preceding paper (above noted) from a crystallographic viewpoint. The new suggestions "do not conflict with the X-ray evidence", whereas certain previously proposed formulas do show such a discrepancy.

"The new suggestions plainly call for a much more thorough crystallographic examination of calciferol itself and its related compounds, particularly pyrocalciferol, isopyrocalciferol, and the two dihydrocalciferols. With such complicated compounds the X-ray method does not lead directly to a formula, but once there are definite formulas to choose from it may usefully serve to discriminate between them."

**On the mechanism of lysozyme action**, K. MEYER, J. W. PALMER, R. THOMPSON, and D. KHORAZO (*Jour. Biol. Chem.*, 113 (1936), No. 2, pp. 479-486).—From this study of the lytic action of lysozyme on susceptible bacteria the authors conclude that "lysis cannot be explained on a physical basis; e. g., lowering of surface tension. Lysozyme has no protease, kinase, amylase, lipase, or phosphatase activity. It liberates reducing sugar from mucoids or polysaccharides of the susceptible *Sarcinae* and from a mucoid fraction of egg white. The type of linkage attacked is not known."

**Retarding rancidity**, W. L. MORGAN (*Indus. and Engin. Chem.*, 27 (1935), No. 11, pp. 1287-1290, figs. 8).—"Blue and invisible ultraviolet light materially accelerates the development of rancidity in such materials as potato chips, crackers, cakes, butter, candies, nuts, and soaps, whereas other visible light such as red and yellow has little effect. Consequently rancidity-retarding wrappers may be of any visible color except blue. Highly protective yellow transparent cellulose films have been developed and utilized for food packaging."

**Second report on the corrosion of the tinplate container by food products**, T. N. MORRIS and J. M. BRYAN (*[Gt. Brit.] Dept. Sci. and Indus. Res., Food Invest., Spec. Rpt.*, 44 (1936), pp. VI+54, figs. 33).—Extending the findings of a report already noted (*E. S. R.*, 68, p. 296), the authors present their more recent results in five chapters dealing, respectively, with the corrosion of tin, the corrosion of mild steel, the tin-iron couple and tin plate, discoloration of canned fruits, and miscellaneous points of technic.

"It is suggested that in all probability the corrosion of cans by foodstuffs will eventually be overcome by improvements in lacquers and methods of lacquering. Failing such a development, relief must be sought through improvements in the tin coating, improvements in the steel base, the cool storage of canned goods, and the application of knowledge concerning the corrosion of tin plate."

Methods of effecting such improvements are discussed, and experiments that throw further light on the factors affecting the formation of hydrogen swells and perforations and the discoloration of canned fruits are described.

**Treating fruits and nuts in atmospheres containing ethylene**, E. M. CHACE and D. G. SORBER (*Food Indus.*, 8 (1936), No. 6, pp. 292-294, figs. 4).—On the basis both of experiments conducted by the U. S. D. A. Bureau of Chemistry and Soils and of their experience with the ethylene treatment, the authors find, with respect to temperature, that the best results have been obtained between 70° and 80° F., the process being slow below 60° and the

results the poorest when the temperature exceeds 90°. The humidity, at least in the case of the citrus fruit treatment, should apparently be about 90 percent. Ethylene concentrations of the order of 1 part to 2 parts per 10,000 have proved effective. Carbon dioxide concentrations of 1 percent have been found to retard the coloring process, and, in the case of oranges, 2 percent has proved harmful. In view of this fact, and the greatly increased respiration observed ("with citrus fruits . . . sometimes as much as 200 percent"), frequent and effective ventilation is thought advisable. A final section on the "nature of the reaction" notes that the reaction "is apparently closely connected with enzyme activity, but whether this is due merely to a change in the permeability of the cell wall or to some catalytic effect on the enzyme is not known. In some ways ethylene acts very much like a plant hormone or auxin. It is now well established that it is a natural constituent of the respiratory gases of fruits in storage and is given off by fruits and vegetables generally when they are injured." It is emphasized that "as far as we have been able to discover, the ethylene treatment brings about no changes which do not occur naturally in the fruits. It merely speeds up natural reactions.

"Whether the reactions taking place naturally are activated by the ethylene normally present in the fruits cannot be said at present. The fact that ethylene is present and apparently takes part in the normal functions of plants, and that no reactions not common to natural ripening have been found, should go a long way in answering criticisms on the use of this gas in coloring."

**Apple thinnings as source of pectin**, Z. I. KERTESZ (*Farm Res. [New York State Sta.]*, 3 (1937), No. 2, pp. 6, 11, 14).—"Approximately 1 lb. of concentrated pectin sirup can be obtained from 5 lb. of thinnings. Even when allowance is made for all the expense involved, the cost of the pectin extract from apple thinnings should not exceed one-fourth the cost of commercial pectin extracts on the market. The use of thinnings thus may result in considerable saving, especially where large quantities of jams and jellies are made."

Hot-water extraction and a method of extracting with cold 0.5 percent hydrochloric acid are both described, as is also the concentration of the extract.

**Manufacture of champagne and sparkling Burgundy**, F. M. CHAMPLIN, H. E. GORESLINE, and D. K. TRESSLER (*Indus. and Engin. Chem.*, 27 (1935), No. 11, pp. 1240-1243, figs. 6).—The authors discuss the essential features of the champagne-making process as carried out with American wines, in a joint contribution from the New York State Experiment Station, the U. S. D. A. Bureau of Chemistry and Soils, and a New York State commercial winery.

**Precipitation rate of cream of tartar from wine**, G. L. MARSH and M. A. JOSLYN (*Indus. and Engin. Chem.*, 27 (1935), No. 11, pp. 1252-1257, figs. 8).—Experiments reported from the California Experiment Station show that the precipitation of cream of tartar from new wines is hastened by cold storage, the rate of precipitation depending on the storage temperature and on the type of wine. The rate is more rapid during freezing storage than in cold storage. The actual amount of cream of tartar to be removed from wine for stabilization cannot be predicted from the data available since so many factors determine the actual solubility of cream of tartar in wine.

**Pasteurization of New York State wines**, C. S. PEDERSON, H. E. GORESLINE, and E. A. BEAVENS (*Indus. and Engin. Chem.*, 27 (1935), No. 11, pp. 1257-1265, figs. 8).—The New York State Experiment Station, cooperating with the U. S. D. A. Bureau of Chemistry and Soils, has shown that New York State dry and sweet wines of low alcohol content can be stabilized effectively by pasteurizing at 130° F. for 20 min. and that this pasteurization can be carried out, under suitable control, in bulk, in closed bottles, or in open bottles. "The micro-organisms which occasionally survive the pasteurization at this

temperature are not of the spoilage type and apparently have but little significance."

**Experimental malting: Design and operating of laboratory malting equipment,** J. A. SHELLENBERGER and C. H. BAILEY (*Brewers Tech. Rev.*, 11 (1936), No. 1, pp. 3-5, figs. 4).—The authors describe a relatively small and inexpensive set-up designed at the Minnesota Experiment Station for experimental and testing use in the laboratory. The equipment is electrically operated and provides for steeping, germinating, and drying. The malting procedure, adapted for use with apparatus of this size, is described.

**Chemistry of slash-pine (*Pinus caribaea*, Morelet).—II, Fats, waxes, and resins of the growing tips,** J. A. HALL and O. GISVOLD (*Jour. Biol. Chem.*, 113 (1936), No. 2, pp. 487-496).—Extending their earlier work (*E. S. R.*, 75, p. 4) on the components of the phloem of the same species, the authors report upon an investigation in which a light petroleum (boiling point from 60° to 70° C.) extract of the young growing tips of *P. caribaea* yielded the following substances: Paraffins of the C<sub>25</sub>-C<sub>30</sub> range, a trace of  $\alpha$ -pinene, melissic acid, melissyl alcohol, *n*-nonacosan-10-ol, a sitosterol and a sitosterolin, palmitic and behenic acids, oily acids apparently consisting of oleic and linoleic acids, and abietic acid.

**Lignin in Douglas fir,** A. J. BAILEY (*Indus. and Engin. Chem., Analyt. Ed.*, 8 (1936), No. 1, pp. 52-55, figs. 2).—The author of this contribution from the University of Washington notes that "the middle lamella has been subjected to extensive research, yet our knowledge of its structure and composition is far from complete." By means of a micromanipulator operated under a magnification of 100 diameters he was able to obtain samples of the isolated middle lamella sufficient for analysis by a micromethod. The lignin content of a single sample weighing 0.521 mg was found to be 71.38 percent. "Samples of wood rays, springwood, and summerwood weighing approximately 3 mg gave values of 41.09, 35.24, and 31.56 percent, respectively, all values being based upon the original oven-dry weight of the isolated material."

**An electrically heated melting point apparatus,** E. DOWZARD and M. J. RUSSO (*Indus. and Engin. Chem., Analyt. Ed.*, 8 (1936), No. 1, pp. 74, 75, figs. 2).—A Pyrex tube 80 by 180 mm is set concentrically through an asbestos cover into a battery jar and is heated by five turns of thin, narrow Nichrome ribbon serving as an electrical resistance unit. A Pyrex test tube concentrically set through the asbestos cover of the larger Pyrex tube carries the melting point thermometer, another thermometer is set midway between the test tube and the wall of the larger Pyrex tube, and the whole is placed upon a base containing an adjustable "radiostat" and an ammeter in series with the heating element. A drawing and a photograph illustrate the device, for which the necessary constructional directions are given.

The apparatus "is suitable for the determination of melting points up to about 310° C., with a reproducibility of within 0.5°."

**A precision pycnometer for liquids,** S. T. YUSTER and L. H. REYERSON (*Indus. and Engin. Chem., Analyt. Ed.*, 8 (1936), No. 1, pp. 61, 62, fig. 1).—In an investigation at the University of Minnesota, in which numerous determinations for the measurement of very slight differences in density were made, "several common types of laboratory pycnometers were tried, but the results were not very satisfactory. The chief faults found were difficulty of thermostating both the liquid and container, evaporation losses at ground-glass joints, loss of liquid during filling (very important in handling expensive liquids), and difficulty of determining the density at some definite temperature."

An apparatus obviating the difficulties named is described and illustrated by a drawing, and its manipulation is detailed.

**Self-sealing vessels for storage of solutions used in the Van Slyke gasometric methods**, F. E. HOLMES (*Jour. Biol. Chem.*, 113 (1936), No. 2, pp. 411-415, fig. 1).—The two types of vessels described were designed to eliminate the glass stopcock in the alkaline stream of the vessel used by Van Slyke, Page, and Kirk (*E. S. R.*, 71, p. 587) and the modified Hempel pipette of Van Slyke and at the same time automatically to provide a mercury seal for the tip of the delivery tube of the simple soda-lime tube of Van Slyke and of its modified forms. "They are especially convenient for those methods in which the solution is passed through a mercury seal in the cup of the Van Slyke pipette and its volume measured in the chamber, for example, for the storing and transferring of 0.5 N NaOH in the carbon combustion method of Van Slyke, Page, and Kirk."

The author describes and illustrates by means of drawings two forms of the apparatus which he has found to give excellent results and a third form which he describes as "a simpler but less satisfactory alternative form" of the first type.

As an illustration of the protection against contamination by carbon dioxide, it is noted that "a strongly alkaline phosphate solution has been stored for nearly 2 yr. without producing any change in the blank in the method in which it is used."

**A sensitive check valve**, E. L. GREEN (*Indus. and Engin. Chem., Analyt. Ed.*, 8 (1936), No. 1, p. 40, fig. 1).—The apparatus described was devised at the U. S. D. A. Bureau of Plant Industry to prevent solutions under treatment with hydrogen sulfide from being drawn back into the gas-purifying train when the gas stream is accidentally interrupted. Water through which the gas must pass is made to float a valve-closing part up against its valve seat, so that a slight but definitely positive gas pressure is necessary to keep the valve open and a zero or negative pressure closes it at once. The parts are two simply blown glass pieces with an outer jacket consisting of a test tube and two-hole stopper. A drawing shows the construction of the device.

**A differential refractometer**, D. RAU and W. E. ROSEVEARE (*Indus. and Engin. Chem., Analyt. Ed.*, 8 (1936), No. 1, pp. 72, 73, figs. 3).—The instrument described was designed at the University of Wisconsin "to be a rapid and reliable instrument for determining concentrations of solutions too dilute to permit the use of the Pulfrich or immersion refractometers. It makes use of the bending of a ray of light when passed through a rectangular cell containing a triangular compartment, the former being filled with pure solvent and the latter with solution." As compared with other instruments of somewhat similar optical principle, the new design "is much more practical because of the new method of observing and measuring the deflection and of determining the zero reading."

**Official and tentative methods of analysis of the Association of Official Agricultural Chemists**, compiled by E. M. BAILEY ET AL. (*Washington, D. C.: Assoc. Off. Agr. Chem.*, 1935, 4. ed., [rev.], pp. [XIX]+710, figs. 52).—This is a revised and somewhat enlarged edition of this standard work (*E. S. R.*, 55, p. 11). Important additions include, in the chapter on soils, a method for the determination of selenium and a method for evaluating fertilizers with respect to their acid-forming or nonacid-forming properties; in the chapter on insecticides and fungicides, a method for determining the phenol coefficient; in the chapter on plants, a method for estimating lignin; and, under the head of grain and stock feeds, a vitamin D assay by preventive biological test.

**Standard iodine solutions**, A. H. SCOTT (*Jour. Biol. Chem.*, 113 (1936), No. 2, pp. 511-513).—Using a standard arsenious acid which was repeatedly checked and did not change during the period of its use, the author found that when

0.1  $N$  iodine in 0.12  $M$  potassium iodide is diluted with distilled water and titrated immediately without further addition of potassium iodide there is a loss in equivalence.

A small quantity of iodine was dissolved in water without any potassium iodide. This solution was then used to titrate a dilute solution of arsenious acid (0.0001  $N$ ), with starch as the indicator. At the end point potassium iodide was added to make about a 5 percent concentration (0.3  $M$ ). The solution then became an intense blue. The additional amount of iodine made available for titration by the addition of the potassium iodide was determined in a second titration with 0.0001  $N$  arsenious acid. The results of such titrations of several dilutions of the original iodine solution showed clearly that a much closer approach to equivalence was secured by adding potassium iodide to the iodine solution in each case in a quantity sufficient to bring the concentration of the salt to 0.3  $M$ . "In addition there must be a final concentration in the titration of 0.3  $M$  KI." Iodine solutions containing potassium iodide in the concentration specified were stable throughout several months. Attention is called, however, to the facts that potassium iodide may contain some free iodine, and that in any case, its solutions liberate free iodine, especially when they are exposed to light. "It is essential, therefore, that the KI solution be made up just before use."

**A method of analysis for fluoride,** W. M. HOSKINS and C. A. FERRIS (*Indus. and Engin. Chem., Analyt. Ed.*, 8 (1936), No. 1, pp. 6-9).—In a contribution from the California Experiment Station the authors report a study of the estimation of fluoride by titration with standard thorium solution in the presence of sodium alizarin sulfonate as indicator. "The most favorable procedure includes the use of the indicator at a concentration of  $4 \times 10^{-5}$  percent, in a total volume of 50 cc, titration to match a blank in which the end point is taken at a very light-pink shade, and careful regulation of the pH in both blank and sample, the most favorable pH being 3.5. This latter condition is readily met by the use of the buffer system of sodium hydroxide and chloroacetic acid at a ratio of 0.5 and total concentration of 0.02  $M$ . The dissociation constant of chloroacetic acid in 50 percent commercial alcohol has been found to be  $2.8 \times 10^{-4}$ . Sodium alizarin sulfonate in this alcoholic solution acts as an indicator for H ion over the pH range 4.8 to 7.2 instead of 3.7 to 5.2 as in water. In a volume of 50 cc an average accuracy of 99 percent has been secured with known amounts of fluoride ranging from 57 $\gamma$  to 760 $\gamma$  of fluorine. With 50-cc volumes approximately the same accuracy is possible with 6 $\gamma$  to 90 $\gamma$  of fluorine."

Data indicating the concentrations at which several interfering ions have an effect are given. The most serious of these interferences were those caused by sulfate, arsenate, and phosphate, "which fortunately are left behind when the fluoride is distilled as hydrofluosilicic acid. Sulfuric acid is entirely suitable for the distillation, and a volume of 200 cc distilled at 140° C. accounts for all but a trace of the fluoride. In the ashing of fruit samples containing fluoride for distillation it is very important not to allow the temperature to reach above 800°, for loss is then excessive. Allowance must be made for the fluoride contained in the lime which is added to the sample before ashing. Recovery of fluoride added to apple pulp was 97.3 percent under the most favorable conditions."

**A source of loss of ammonia in Kjeldahl distillations,** H. S. MILLER (*Indus. and Engin. Chem., Analyt. Ed.*, 8 (1936), No. 1, pp. 50, 51).—The author finds that there is a loss of ammonia by the usual Kjeldahl distillation procedure due to the fact that some ammonia during the first few minutes of distillation is diluted with air to such an extent that part of it escapes absorp-

tion by the standard sulfuric acid through which it passes. The average loss of nitrogen resulting from 47 determinations with ammonium chloride solution was shown to be 1.26 percent, the average deviation being  $\pm 1.24$  percent.

"The usual Kjeldahl procedure has been improved by the use of a delivery tube containing holes, each 0.08 mm in diameter, which cause the air bubbles resulting during the first few minutes of distillation to be broken up to such an extent that the average loss of nitrogen resulting from 8 determinations is 0.06 percent, with an average deviation of  $\pm 0.12$  percent."

**Copper selenite as a catalyst in the Kjeldahl nitrogen determination,** E. J. SCHWÖGLER, B. J. BABLER, and L. C. HURD (*Jour. Biol. Chem.*, 113 (1936), No. 3, pp. 749-751).—As the result of an investigation at the University of Wisconsin, copper selenite dihydrate is proposed as a single catalyst in the Kjeldahl digestion of nitrogenous materials. The time required for clearing and for complete digestion was considerably less in the cases studied than that required when other conventional catalysts were used. As an illustration of the differences between the effects of copper selenite and of other catalysts, "duplicate samples of a homogenized corn meal were digested under uniform conditions with 25 ml of  $\text{H}_2\text{SO}_4$ , 12 g of  $\text{K}_2\text{SO}_4$ , and 0.3 g of  $\text{CuSeO}_4 \cdot 2\text{H}_2\text{O}$ . It was found that with 12 samples weighing between 0.2 and 2 g the average clearing was 13 min., as compared to 23 min. when the same series was digested with 25 ml of  $\text{H}_2\text{SO}_4$ , 10 g of  $\text{K}_2\text{SO}_4$ , 0.7 g of  $\text{HgO}$ , and 0.3 g of  $\text{CuSO}_4$  and 17 min. when 25 ml of  $\text{H}_2\text{SO}_4$ , 10 g of  $\text{K}_2\text{SO}_4$ , and 0.1 g of Se were used."

**An apparatus for sugar and other titrations,** E. S. WEST (*Indus. and Engin. Chem., Analyt. Ed.*, 8 (1936), No. 1, p. 62, fig. 1).—Essential features of this set-up are a vertically oscillating stirrer operated by a windshield wiper mechanism and the use of a stainless-steel hypodermic needle as a burette tip. The note is illustrated by a drawing, and the more important dimensions are specified.

**Gravimetric methods for the determination of total body protein and organ protein,** T. ADDIS, L. J. POO, W. LIW, and D. W. YUEN (*Jour. Biol. Chem.*, 113 (1936), No. 2, pp. 497-504).—This general procedure "is first to prevent autolysis and to render the proteins insoluble by immediate immersion of the carcass and excised organs in a boiling 0.5 M sodium acetate-acetic acid buffer solution kept at pH 5. The material is then reduced to a form in which it can be sampled by methods which vary with the physical character of each organ or part. Water-soluble substances are washed out with acetate buffer, fats, and acetate with hot alcohol, and finally water is removed by drying in vacuo. The remainder is weighed. Nonprotein material which cannot be removed, such as minerals derived from bone, and glycogen that cannot completely be washed out from the liver, are determined and subtracted. The material thus measured is regarded as giving the nearest approximation to the amount of the protein structure required for the manifestation of vital phenomena, the essential machinery stripped of storage material and accessories and separated from the medium within which it operates."

**An improvement on the Swift fat stability apparatus for approximating the end of induction period,** V. C. STEBNITZ and H. H. SOMMER (*Oil & Soap*, 12 (1935), No. 9, pp. 201, 202, fig. 1).—At the Wisconsin Experiment Station the authors substitute a test based upon the development of volatile acidity for the odor test as an indicator of the end of the induction period. The exhaust from the tubes in which the fat is aerated is passed into test tubes containing 1 cc each of 0.01 N sodium hydroxide diluted in water sufficient to cover the ends of the delivery tubes, and to this solution is added about 2 drops per tube of methyl red indicator solution. The change from yellow to pink is taken as the end point.

**Determination of reduced ascorbic acid in blood**, M. PIJUAN, S. R. TOWNSEND and A. WILSON (*Soc. Eapt. Biol. and Med. Proc.*, 35 (1936), No. 2, pp. 224-226, fig. 1).—Discrepancies in the results obtained in duplicate and triplicate readings on the same sample of plasma in the determination of the reduced ascorbic acid in the blood by the method of Farmer and Abt (*E. S. R.*, 75, p. 588) led to an investigation of the stability of the ascorbic acid in the blood plasma on standing. In this preliminary report data are given showing that the ascorbic acid value of the blood is materially affected by standing either in the ice box or at room temperature. It is stated that determinations should be carried out within  $\frac{1}{2}$  hr. after the collection of the blood.

**Determination of formic acid in pyroligneous liquors**, H. D. WEIHE and P. B. JACOBS (*Indus. and Engin. Chem., Analyt. Ed.*, 8 (1936), No. 1, pp. 44-47, figs. 3).—A method for the convenient determination of formic acid in pyroligneous acid, based upon the removal of certain volatile and nonvolatile interfering substances, followed by the oxidation of the formic acid to carbon dioxide in a closed system using mercuric acetate as oxidizing agent, is presented in a contribution from the U. S. D. A. Bureau of Chemistry and Soils.

### AGRICULTURAL METEOROLOGY

**Handbook of climatology, I (B-C)**, edited by W. KÖPPEN and R. GEIGER (*Handbuch der Klimatologie. Berlin: Borntraeger Bros.*, 1936, vol. 1, pt. B-C, pp. VIII+[2]+XII+B1-B556, figs. 96; pp. C1-C44, figs. 14; +pp. 12).—This part of a projected 5-volume handbook of climatology deals with Climatological Elements and Their Dependence on Terrestrial Influences, by V. Conrad; and the Geographic System of Climates, by Köppen; and gives title, preface, contents, and alphabetical index of volume 1. Parts of the handbook previously issued have been noted (*E. S. R.*, 65, p. 413; 67, pp. 211, 654; 68, pp. 156, 157; 72, p. 446).

**Relations between solar and terrestrial phenomena** (*Relations entre les phénomènes solaires et terrestres. Firenze (Florence): Cons. Internat. Unions Sci.*, 1936, pp. 159, figs. [17]; rev. in *Nature [London]*, 138 (1936), No. 3488, p. 397).—This is the fourth report of the Commission for the Study of Solar and Terrestrial Relationships, set up in 1924 by the International Council of Scientific Unions. In addition to an introductory chapter by G. Abetti giving a general survey of the subject for the past three years, brief articles are included on solar radiation and phenomena, magnetic conditions of the earth, polar auroras, propagation of radioelectric waves, absorption in the upper atmosphere of the earth, cosmic rays, light of the night sky, and meteorological and climatological variations on the earth.

**The influence of forests on climate and water supply in Kenya**, [I], II, III, J. W. NICHOLSON (*East African Agr. Jour.*, 2 (1936), Nos. 1, pp. 48-53; 2, pp. 164-170; 3, pp. 226-240).—Reviewing the available information regarding influence of forests on temperature, rainfall, run-off, stream flow, evaporation, and other factors, with special reference to Kenya, the author concludes that "some forests may be of very local climatic influence; the majority exercise a regional influence on climate." These latter must be recognized as a national asset, especially as regards equalization of rainfall, stream flow, run-off, and winds.

**Comparative measurement of temperature in the zone of plant climate** [trans. title], E. TAMM (*Landw. Jahrb.*, 83 (1936), No. 4, pp. 457-554, pl. 1, figs. [53]).—Observations on air and soil temperatures at 5 and 30 cm above and below the soil in winter rye, winter wheat, oats, summer barley, and potatoes, as compared with temperatures in the open, showed as distinct difference of temperature conditions in crops like cereals harvested in the first half of the

summer as in those of lower growth like potatoes harvested later. Temperatures of air and soil were higher in the cereals, reaching their maximum in July, than in potatoes, which grew throughout the season.

The set-up and procedure used in the observations and the interpretation of the data are explained in detail.

**Weather in cycles**, B. HIBBS (*Country Gent.*, 107 (1937), No. 2, pp. 7, 8, 79-82, figs. 3).—This is a popular exposition of C. G. Abbot's views regarding influence of variations in solar radiation and sunspot cycles on terrestrial weather.

**Climatic index of crop risks** [trans. title], KRISCHE (*Ernähr. Pflanze*, 32 (1936), No. 15-16, p. 268; abs. in *Ann. Agron. [Paris]*, n. ser., 6 (1936), No. 6, p. 896).—An index obtained by dividing the highest yields of various crops in different parts of Germany by the lowest yields during a period of 10 years is briefly explained and discussed.

**The influence of rainfall on the yield of a natural pasture**, H. C. TRUMBLE and E. A. CORNISH (*Jour. Council Sci. and Indus. Res. [Austral.]*, 9 (1936), No. 1, pp. 19-28, figs. 3; abs. in *Ann. Agron. [Paris]*, n. ser., 6 (1936), No. 6, p. 894).—In a study of the influence of amount and distribution of rainfall on natural pasture, consisting predominantly of *Danthonia*, with smaller quantities of exotic annuals such as *Festuca myuros*, *Trifolium arvense*, *T. procumbens*, *Erodium botrys*, and *Echium plantagineum*, top-dressed with superphosphate and grazed by sheep, "high significant positive correlations were obtained between the yield of each pasture and the rainfall for January-December, January-June, the trimonthly and bimonthly periods between February and July, and the single month of April. The correlation was strongest in the period April to June, inclusive, which coincides with the early stages of seasonal growth. High significant negative correlations were found between the yield of each pasture and November rainfall. There was, however, a significant negative relationship, for the 10 years in question, between April-June rainfall and November rainfall. Elimination of this effect by partial correlation reduced the association between November rainfall and yield to insignificance. The effectiveness of autumnal and early winter rainfall and the relative ineffectiveness of late winter and spring rainfall in determining yield appear to be associated with the type of pasture investigated, which is composed of species with a restricted growing period and a limited capacity for production. The replacement of these species by cultivated herbage plants with a perennial deep-rooted habit and a capacity for growth over all or most of the year enables the rainfall to be used more effectively, and constitutes an important application of the results in practice."

**Smudging for frost protection** [trans. title], A. HOVD (*Meld. Norske Myrselskaps Forsøkssta. Maeresmyra*, 24-25 (1931-32), pp. 36-46, figs. 4; abs. in *Bioklim. Beibl. Met. Ztschr.*, 3 (1936), No. 3, p. 141; *Ann. Agron. [Paris]*, n. ser., 6 (1936), No. 6, p. 891).—This article reports successful use of smudges produced by pine woods litter, sphagnum moss, and peat briquettes as protection against frost, and advises application of fertilizers, especially potash, to hasten maturity.

## SOILS—FERTILIZERS

**Soils: Their origin, constitution, and classification**, G. W. ROBINSON (*New York: D. Van Nostrand Co.*, 1936, 2. ed., rev., pp. XVII+442, pls. 5, figs. 17).—This is a revised edition of a work (E. S. R., 68, p. 733) the basic outline of which has been altered only in the omission of an appendix on soil analysis. "I have only included such new work as has modified my earlier views and have by no means attempted to record everything that has been written on soils in the intervening years. . . . The facts which have come to my

notice have fallen into a certain perspective and have produced my picture of the soil. Another pedologist might arrange the same facts in a different perspective and produce another picture."

**The study of the soil in the field, G. R. CLARKE** (*Oxford: Univ. Oxford, Imp. Forestry Inst., 1936, pp. 142, figs. 7*).—This book is mainly a discussion of various soil surveying systems in present use, the treatment being that of a guide for the field worker. Following a preface by C. G. T. Morison, the book contains chapters on soil site characteristics, the soil-profile pit, soil-sample collection (monolith collection), mapping of soils, and notes on various soil-survey systems, including those of Bayern (Bavaria), Hungary, Russia (landscape), Macaulay Institute for Soil Research, America (series), English soil series survey, and English regional survey. A condensed index concludes the volume.

**[Soil investigations of the California Station]** (*California Sta. [Bien.] Rpt. 1935-36, pp. 11-15, 20*).—The topics upon which brief reports are here made include permeability of soils, effect of puddling on permeability, effect of irrigation and cropping on soil temperatures, soil temperatures at various depths, soil colloids, basaltic lava soils, potassium in California soils, and soil deficiencies (zinc).

**[Soil work, Hawaii Station], O. C. MAGISTAD ET AL.** (*Hawaii Sta. Rpt. 1936, pp. 42-44*).—This work has included correlation of results of field experiments with laboratory and greenhouse tests, moisture surface force curves, and oxidation-reduction potential.

**A handbook on Hawaiian soils, W. W. G. MOIR ET AL.** (*Honolulu: Assoc. Hawaii. Sugar Technol., 1935, pp. VI+266, figs. [44]*).—"For some time there has been a need for a reference book on the various phases of soil science and their relation to Hawaiian soils in particular. . . . The information has been available, but scattered through so many publications that it has been next to impossible for those interested in the agricultural industries of these islands to be able to refer to these publications. . . . As a mutual aid to each other in their respective fields of work and as an aid to those seeking the basic information, a committee of those responsible for much of the soil research in Hawaii has rather hurriedly compiled a series of lectures on these subjects. . . . It has been the desire of the committee to keep the subject matter somewhat elementary so as to meet the desires of many men in the industries who have not been as fortunate as others in securing an education along these lines. There is, however, sufficient data and enough advanced discussion presented to make them of value to anyone."

The contents are as follows: Soil making processes, by H. S. Palmer; chemical aspects, by W. W. G. Moir et al.; physical aspects, by H. A. Wadsworth; microbiological aspects, by O. N. Allen; soil management, by N. King et al.; and soil survey methods of classification and study, by L. R. Smith.

**Nevada soils: An outline of proposed investigations, V. E. SPENCER** (*Nevada Sta. Bul. 144 (1936), pp. 17, figs. 4*).—The author points out the relative increase in the importance of agriculture as one of the major industries of the State, calls attention to an already evident depletion of the native fertility of the soils long in use, and emphasizes the importance of the completion of the State soil survey, the necessity for establishing field experiments, and the value of laboratory and greenhouse investigations, soil testing, a State fertilizer law, and laboratory fertilizer control work.

**[Soil researches of the Cornell Station]** (*[New York] Cornell Sta. Rpt. 1936, pp. 74, 76*).—The report contains brief notes on the influence of fertilizers on the loss of microscopic organisms from soils, by J. K. Wilson; and nitrogen balance in soil under different cropping systems, by T. L. Lyon and J. A. Bizzell.

**Some animal relations to soils**, W. P. TAYLOR (*Ecology*, 16 (1935), No. 2, pp. 127-136).—This contribution from the U. S. D. A. Bureau of Biological Survey discusses the following among other ways in which animals influence the development and stability of soils: Accumulating animal bodies or parts; accumulating materials for houses, shelters and nests, and storage of food material; soils packing; dam building and flooding; digging of burrows and associated soils working; promoting erosion; and preventing erosion.

**Neutralization curves of the colloids of soils representative of the great soil groups**, M. S. ANDERSON and H. G. BYERS (*U. S. Dept. Agr., Tech. Bul. 542* (1936), pp. 39, figs. 13).—From a study of the chemical composition of extracted colloids of the profiles of various major soil groups, their exchangeable bases, their titration curves, and the titration curves of such sparingly soluble substances as tungstic acid, mucic acid, ferric hydroxide, aluminum hydroxide, and silicic acid, the authors have obtained data upon which they base the following, among other conclusions:

"The pH values of electrodialyzed colloids vary with the chemical composition of the colloids. Those with high silica: sesquioxide ratios tend to have lower pH values (2.5 to 3.0), while the pH range of colloids of low ratio is usually from 3.5 to 4.5. The character of neutralization curves made with sodium hydroxide varies widely for colloids of the different soil groups. The colloids of Pedocal soils show the strongest acid character. About 0.55 milliequivalent of sodium hydroxide per gram of colloid is required to produce a pH value of 7. There is considerable evidence of a break in the curve for these colloids between pH 6 and 8. . . . The colloids of the lateritic soils have much weaker acid qualities than those of the Chernozem soils, and their titration curves are of such markedly different form that the two groups are readily differentiated by this means. The Prairie group and the Gray-Brown Podzolic group have titration curves intermediate in character between those of the Pedocal and the lateritic soils. The curves for the colloids of true Podzols are widely different for adjacent horizons of a particular profile, and corresponding horizons of different profiles show wide variation in acidic qualities as well as in chemical composition.

"The acid character of the colloidal organic matter is in most cases so pronounced that when such organic matter is present in considerable quantity it tends to obscure the behavior of the inorganic portion. The acid qualities of the bentonite colloids are distinctly stronger than those of the inorganic soil colloids but weaker than humic acid extracted from the soil. The acid character, brought out by titration data, is related in a general way to the fertility of a soil."

**Lysimeter experiments**.—IV, Records for tanks 17 to 20 during the years 1922 to 1933, and for tanks 13 to 16 during the years 1913 to 1928, T. L. LYON and J. A. BIZZELL ([*New York*] *Cornell Sta. Mem. 194* (1936), pp. 59).—The conclusions recorded in the present memoir, which extends a series earlier noted (*E. S. R.*, 64, p. 520), were drawn from experiments on 4-ft. depths of Petoskey gritty sandy loam, placed in the lysimeter tanks in 1921; on Volusia silt loam tanks under experimental treatment since 1910; and from a comparison of the results with those of the experiments on Dunkirk silty clay loam, set forth in Memoir 12 (*E. S. R.*, 39, p. 517).

"With every soil, the nitrogen contained in the drainage water was practically all in the form of nitrates, there being only traces of organic, nitrous, or ammoniac nitrogen present. In all three soils there was a marked decrease of nitrogen in the drainage water from the planted soil as compared with the

soil on which no plants were grown. . . . The amount of nitrogen in the crops and in the drainage water combined was greater from the limed than from the unlimed Volusia soil, but this was not the case with the other two soils. . . .

"Calcium was the cation removed in largest amount in the drainage water from each of the three soils. The Dunkirk soil lost the largest amount of calcium, the Volusia lost less, and the Petoskey lost the least. The removal of calcium was larger in every case from the unplanted than from the planted soil. . . . There was a conservation of calcium effected by cropping, even when the entire above-ground parts of the plants were removed. . . . Only on the Volusia soil [on which plant growth responded most favorably to liming] did liming increase the amount of calcium removed in the drainage water. This effect was considerable. . . .

"In no soil did the magnesium removed in the drainage water approach in amount the calcium so removed. In all three soils, the percentage of magnesium was higher than that of calcium, except in the fourth foot of the Dunkirk. Like calcium, magnesium was present in greater amount in the drainage water from the unplanted soil than in crops and drainage water combined on the soils that were planted. The effect of liming on the loss of magnesium in the drainage water was not perceptible in the case of the Petoskey soil. The limed Dunkirk yielded somewhat more magnesium in the drainage water than did the unlimed, but the Volusia released 33 percent more magnesium in the drainage from the limed than from the unlimed soil.

"All the soils lost more potassium than magnesium in the drainage water, but less potassium than calcium. As between the three soils there was no great difference in the amount of potassium removed, especially as between the Dunkirk and the Petoskey, but the removal from the Volusia was somewhat less. The crops grown on the Dunkirk soil contained more potassium than did the drainage water from the same tanks. The reverse was true of the other two soils. This may possibly be accounted for by the better growth of plants on the Dunkirk soil. Potassium was not conserved by the growth of plants on the soil, as were calcium and magnesium. Potassium appears to be less influenced by the nitrate ion. In general, the results from liming did not indicate that the solubility of potassium was increased thereby.

"The amounts of sulfur in the drainage water from the Petoskey and the Dunkirk soils were about equal for the corresponding soil treatments. The Volusia soil yielded somewhat less sulfur in the percolate. The amount of sulfur in the crops was least for the Petoskey soil, was somewhat greater for the Volusia, and was greatest for the Dunkirk soil. In all cases there was much more sulfur in the drainage water than in the crops. When the sulfur in the crops was added to that in the drainage water, the removal from the planted and from the unplanted soil was not greatly different, especially in the Dunkirk and Petoskey soils. The large surplus of sulfur in the drainage water probably accounts for the failure of plant growth to respond to applications of sulfur to these soils. While there was slightly more sulfur in the drainage water from the limed than from the unlimed soil in all three of the soil types, the differences were so small that they are of doubtful significance. Differences in the amounts of sulfur in the crops were also slight and were not uniform. . . .

"Only traces of phosphorus were found in the drainage water from any of the three soils. The only data on phosphorus removal are therefore confined to the phosphorus contained in the plants. As the yields of crops were larger on the Dunkirk soil than on the other two types, the total quantity contained in the crop was larger. The percentage of phosphorus in the crops

from the Dunkirk and from the Volusia soil was about the same. That in the Potoskey soil was somewhat higher. With all three soils, the percentage of phosphorus was slightly greater in the crops grown on the limed tanks than in those on the unlimed tanks."

Appendix A outlines the methods of analysis used, and appendix B contains 12 additional tables of data concerning flow of drainage water and related matters.

**Base exchange in soil separates and soil fractions (sand and silt),** A. T. PERKINS and H. H. KING (*Soil Sci.*, 42 (1936), No. 5, pp. 323-326).—In an investigation carried out at the Kansas Experiment Station, the authors treated Wabash, Summitt, Derby, and Cherokee soils with hydrogen peroxide to destroy all organic matter and fractionated the mineral components of the soils by a sedimentation method into separates having sedimentation periods of (1) 6½ min., to deposit from 2 ft. of water, (2) between 6½ and 40 min., (3) between 40 min. and 4 hr., (4) between 4 and 24 hr., (5) between 24 hr. and 6 days, and (6) material remaining in suspension for more than 6 days. The first four separates were further fractionated, by means of mixtures of carbon tetrachloride and bromoform, into fractions having the specific gravities 2, 2.4, and 2.6. No satisfactory means for fractionating the two finest sedimentation separates into specific gravity fractions was available.

Measurements of the base-exchange capacity of these separates and their fractions on the two bases of milliequivalents per 100 g and of milliequivalents per  $10^{-5}$  cm<sup>2</sup> of estimated particular surface showed that "as particle size in soil separates decreases, base-exchange capacity increases per unit weight but decreases per [unit of] surface area. As particle size in soil fractions decreases, base-exchange capacity of the 2-2.4 fraction remains constant but that of the 2.4-2.6 and 2.6+ fractions increases per unit weight. All soil fractions as they become finer exhibit smaller base-exchange capacity per unit surface area."

**Peat land as a conserver of rainfall and water supplies,** A. P. DACHNOWSKI-STOKES (*Ecology*, 16 (1935), No. 2, pp. 173-177).—The author points out, in a contribution from the U. S. D. A. Bureau of Chemistry and Soils, that "in considering the direct value of peat land to water supplies and the need of conserving precipitation, American peat deposits may be placed into three major zonal groups and further subdivided into minor groups representing more or less definite combinations of physical features, land relief, drainage, and vegetation. . . . The three major zonal groups are (1) the northern group of peat land with an abundance of moisture, (2) the central continental group with a fluctuating and unstable moisture supply, and (3) the group of southern and western peat land with insufficient moisture or a periodic water supply. The problem of water conservation in each of these major groups is naturally different. In a general program of utilizing peat areas as water resources and obviating harmful effects, the plan should include a general reconnaissance of watershed provinces and the correlated factors that limit the use of peat areas in a constructive scheme of water economy or for other national objectives. Retiring large tracts of submarginal peat land offers an opportunity for conserving safeguards against drought, floods, erosion, and lowered ground waters and for restoring the activity of natural vegetation as a constructive factor in the nation's land and water problems."

**How to build up and maintain the virgin fertility of our soils,** G. W. CARVER (*Alabama Tuskegee Sta. Bul.* 42 (1936), pp. 10).—This is a popular discussion of elementary principles of tillage and fertilizer practice.

**The decomposition of organic matter in relation to soil fertility in arid and semi-arid regions, P. C. J. OBERHOLZER (*Soil Sci.*, 42 (1936), No. 5, pp. 359-379, figs. 9).**—Experiments carried out at the University of Arizona indicated that the decomposition of added organic matter was without appreciable effect upon the pH value of calcareous soils.

The solubility of the soil phosphates was practically unaffected by decomposing organic matter, and the effect upon the content of nitrates and other soluble salts appeared to depend mainly upon the chemical nature, and especially the carbon:nitrogen ratio, of the added material. "Percolation studies led to the conclusion that during the first few weeks active decomposition results in large increases of soluble salts, especially calcium bicarbonate. After 6 weeks had elapsed, however, the difference between treated and untreated soils was negligible.

"Alfalfa, hegarl, and manure decompose in the order mentioned when CO<sub>2</sub> production from soils is taken as an index to rates of decomposition. Larger amounts of CO<sub>2</sub> are produced than are reported for humid regions, and maximum production always occurs during the first or second day. Glucose, lignin, cellulose, and starch undergo decomposition in the order mentioned when incorporated with a soil and when rates of decomposition are estimated by CO<sub>2</sub> evolution. . . .

"The rate at which organic matter decomposes increases with increasing moisture up to almost complete saturation. However, considerable losses occur even below the wilting coefficient. . . .

"Decomposition of organic matter increases with temperature, the maximum being around 45° C. as found by CO<sub>2</sub> production from soils. Although microorganisms are sensitive to low temperatures, adaptations are possible, allowing them to function over a relatively wide range of temperature conditions. . . . It appears that temperature is a more important factor than moisture in the decomposition of organic matter, but obviously a combination of the two is the actual criterion. . . .

"Neubauer investigations showed that actively decomposing organic matter is injurious to the growth of seedlings. It further appears that organic matter affects the availability of phosphates only to the extent of its own content of phosphate, but markedly increases the availability of potassium from the soil."

**The influence of organic matter on nitrate accumulation and the base exchange capacity of Dickinson fine sandy loam, H. C. MILLAR, F. B. SMITH, and P. E. BROWN (*Jour. Amer. Soc. Agron.*, 28 (1936), No. 10, pp. 856-866, figs. 7).**—The authors report from the Iowa Experiment Station an investigation involving experiments designed to show the effect of decomposing wheat straw, oat straw, Sudan grass, sorgo, flax, cornstalks, millet, hemp, soybeans, sweet-clover, red clover, and alfalfa on the accumulation of nitrates in the soil, the base-exchange capacity of the soil, and the carbon and humus contents of the soil.

"The accumulation of nitrates in the soil was significantly correlated with the nitrogen content of the material added. The materials having a relatively wide carbon:nitrogen ratio depressed nitrate accumulation in the soil to a greater extent than the materials having a relatively narrow carbon:nitrogen ratio.

"The exchange capacity of Dickinson fine sandy loam was increased materially by the decomposing plant materials in one experiment, and there was no consistent difference in the exchange capacity of the soils treated with the different plant materials as decomposition proceeded in another experiment. The first experiment was carried out under laboratory conditions and at about

25° C., whereas the second experiment was carried out under greenhouse conditions, beginning in July. The air temperature in the greenhouse was frequently above 110° F. The high temperature and the resultant increased decomposition of the materials undoubtedly explain the differences in the effect of the materials on the exchange capacity of the soil. In general, the leguminous materials increased the exchange capacity of the soil more than the nonleguminous materials."

**The value of summer cover crops, R. M. BARNETTE** (*Citrus Indus.*, 17 (1936), No. 7, pp. 5, 20).—A popular discussion from the Florida Experiment Station points out the generally accepted values of cover crops and the reasons for giving preference, when and where it is practicable to do so, to a leguminous cover crop.

**Problems in soil microbiology, D. W. CUTLER and L. M. CRUMP** (*London and New York: Longmans, Green & Co., 1935. pp. VII+104, pl. 1, figs. 18*).—This book condenses the substance of a series of lectures, and "the theme throughout is to show that from the biologist's viewpoint the soil is an eminently suitable home for living organisms and that, through the long ages of evolution, a population has been selected which is on the whole so unspecialized that almost any substance which finds its way into the soil, either naturally or in the course of modern agricultural practice, will eventually become incorporated into the general soil economy. The activities of each micro-organism depend upon those of its fellows, and the threads of all their lives together form a skein which is still inextricably tangled. The whole problem can only be attacked by tracing the threads one by one, and the results of some of these attempts at disentangling the threads are given in this book."

The contents are: The suitability of the soil for micro-organisms, the bacterial population under field conditions, the relation of bacteria to nitrite, carbon dioxide production by soil, the growth of protozoa in pure culture, the behavior of protozoa in soil, the interactions between the soil organisms, a list of literature cited, an index, and a map showing protozoan distribution.

**Adsorption of bacteria by soils, T. C. PEELE** ([*New York*] *Cornell Sta. Mem.* 197 (1936), pp. 18, pls. 2, figs. 3).—The data here presented show that when two widely differing New York soils—Volusia silt loam and Ontario loam—are placed in contact with a suspension of negatively charged bacteria, the bacterial cells are to a large extent removed from suspension and become attached to the soil particles. The attraction of soil for bacteria was found to be markedly influenced by the base predominating in the soil-exchange complex, and it appeared probable that this is the factor which determines whether or not a given soil will absorb a given species of bacteria. The soils saturated with ferric or aluminum ions adsorbed *Azotobacter chroococcum* the most strongly, and the soils saturated with  $\text{Li}^+$ ,  $\text{Na}^+$ ,  $\text{K}^+$ , or  $\text{NH}_4^+$  adsorbed these bacteria the least strongly. Soils leached first with lithium-, sodium-, potassium-, or ammonium-chloride solutions and then with distilled water showed much larger numbers of bacteria passing out in the leachate than did soils leached with water alone. Soils leached with iron- and aluminum-trichloride solutions showed fewer organisms passing through in the leachate than did soils leached with water alone.

Experiments on adsorption of electronegative and electropositive dyes by soils showed a close analogy between the adsorption of electronegative dyes and negatively charged bacteria; that is, the soils which adsorbed the electronegative dyes the most strongly and the electropositive dyes the least strongly were the ones which adsorbed the negatively charged bacteria the most strongly.

Carbon dioxide determinations indicate that adsorption of bacteria very markedly decreases their biochemical activity as measured by the effect on  $\text{CO}_2$ .

evolution. There was a close correlation between the percentage adsorption of the bacteria and the extent to which the soil retarded the evolution of CO<sub>2</sub>.

*Bacillus mycoides* and *Rhizobium meliloti*, as well as *A. chroococcum*, were found to be strongly adsorbed by Volusia silt loam.

"The evidence presented indicates that the adsorption of bacteria by soils is due to the attraction of unlike electrical charges. This offers an explanation also of the strong adsorptive power of iron and aluminum hydrogels toward negatively charged bacteria, the iron and the aluminum being electropositive in acid solution."

**Physiological studies on *Rhizobium* species, D. G. CLARK** ([*New York*] *Cornell Sta. Mem.* 196 (1936), pp. 30).—"In attempting to demonstrate the nitrogen-fixing ability of the root-nodule organism, mass cultures of several *Rhizobium* species containing approximately one billion bacteria per cubic centimeter from young transfers were maintained in modified Ashby's solution under a variety of environmental conditions. Sugar concentration, pressure of atmospheric nitrogen, light intensity, presence of a growth accessory, and association of rhizobia with other organisms (including *Bacillus subtilis*, *Chlorella* sp., and *Azotobacter chroococcum*), were among the variables introduced. Analysis of the cultures showed no significant increases in nitrogen content over that of the controls.

"Results of another experiment, which involved a delicate biological test for fixation, showed that *Chlorella* was unable to grow in a solution free of combined nitrogen inoculated with *Rhizobium*, whereas *Azotobacter* under similar conditions produced excellent growth of the alga.

"It appears that *Rhizobium* is unable to fix atmospheric nitrogen apart from the host, at least under the experimental conditions provided."

The substance responsible for growth acceleration of *R. trifolii* is shown to be soluble in chloroform, carbon tetrachloride, and alcohol and slightly soluble in acetone; insoluble in ethyl ether and petroleum ether; present in brown sugar and "calcium saccharate" and detectable in peptone; absent from cornstarch; destroyed by ashing and wet combustion; dialyzable to about the same degree as are the soluble nitrogen and the ash present in carrot extract; a nonelectrolyte; strongly adsorbed by charcoal; soluble in the presence of lead acetate; and nonvitaminlike in character, not readily oxidized, and nonvolatile.

"By reason of the foregoing facts it may be asserted that the substance in question is an organic complex of relatively low molecular weight, and is probably not one of the specific substances called 'rhizopin', 'auxin', or 'inositol', the active substance from *Rhizopus* having different solubility characteristics, the auxins being easily oxidized and inosite being precipitated by basic lead acetate."

**Influence of rotation and manure on the nitrogen, phosphorus, and carbon of the soil, J. E. GRAVES and C. T. HIRST** (*Utah Sta. Bul.* 274 (1936), pp. 15).—The authors report the effects of an experiment with the rotation oats, beets, beets, oats, and 3 years' alfalfa on the nitrogen, phosphorus, and organic material of an irrigated silt loam. It was found that oats remove more nitrogen than do sugar beets when the crowns are returned to the soil, but when the crowns are also removed the two crops deplete the soil of its nitrogen to the same extent. Properly inoculated alfalfa feeds first on the combined nitrogen of the soil and only when this is insufficient does it draw on the nitrogen of the air. "Hence, rotations in which the alfalfa is removed from the soil do not maintain the nitrogen of this soil. However, there are two practical methods of maintaining the nitrogen of the soil: (1) Planning systems of crop rotations with legumes, the legume being plowed under and allowed to

decay, thus furnishing nitrogen to the succeeding crop; and (2) practicing a combined system of crop rotation and livestock farming, the legume being fed and the manure returned to the soil.

"The rotation investigated in this work showed a loss of 63 lb. of nitrogen from each acre to a depth of 3 ft. Thirty-nine lb. of this was removed by the beets and oats. The balance was either removed by the alfalfa or leached below the third-foot level by the water. Alfalfa removes twice as much phosphorus from the soil as do either oats or sugar beets. During the life of this experiment (18 yr.) analysis showed a loss of 720 lb. of phosphorus from each acre of soil, only 491 of which was removed by the crops; the balance being held in the undecomposed plant residues carried below the third-foot level by irrigation water. The rotation under consideration increased the carbon of the soil and widened the carbon:nitrogen ratio, thus rendering the soil more productive."

**Oxygen and carbon dioxide content of culture solutions in relation to cation and anion nitrogen absorption by tomato plants, L. B. ABBINGTON and J. W. SHIVE** (*Soil Sci.*, 42 (1936), No. 5, pp. 341-357, pl. 1).—The authors report from the New Jersey Experiment Stations an investigation in which oxygen and carbon dioxide were determined in aerated and nonaerated culture solutions, and the cation and anion absorption ratios were determined after the roots of the plants had been immersed in the solutions during 6-hr. test intervals.

"The aerated culture solutions invariably showed a higher oxygen tension than did the corresponding nonaerated solutions at both pH levels. H-ion concentration, as such, had no apparent influence upon the oxygen tension of the solutions. Aeration produced a marked increase in the rates of absorption of cation, anion, and total nitrogen from the culture solutions over the corresponding rates from the nonaerated solutions at both pH levels. The rates of absorption of cation nitrogen from the solutions at pH 7.0 were higher than the corresponding rates at pH 4.0. Conversely, the rates of absorption of anion nitrogen from the solutions at pH 7.0 were lower than the corresponding rates at pH 4.0. Yields produced by the aerated cultures were approximately double the yields produced by the corresponding nonaerated cultures. Rates of total nitrogen absorption (cation plus anion nitrogen) were slightly but consistently higher from solutions at pH 7.0 than from the corresponding solutions at pH 4.0. Growth yields produced by the cultures at pH 7.0 were invariably higher than those produced by the corresponding cultures at pH 4.0, and these paralleled the absorption rates of total nitrogen. Yields of plant material produced by the aerated cultures were approximately double the yields produced by the corresponding nonaerated cultures. Accumulation of carbon dioxide occurred in all solutions in contact with plant roots. Accumulation at pH 7.0 greatly exceeded that at pH 4.0. As the result of the sweeping action of the aerating process, accumulation in the nonaerated solutions invariably exceeded that in the corresponding aerated cultures.

"Carbon dioxide accumulation in the culture solutions appeared to be without effect upon growth, nitrogen absorption rates, or oxygen content of the solutions."

**Summer citrus fertilization, R. W. RUPRECHT** (*Citrus Indus.*, 17 (1936), No. 7, p. 10).—Recommendations specifically adapted to the conditions of the current season are given in a brief note from the Florida Experiment Station.

**A study of the basicity of dolomite, rock phosphate, and other materials in preparing non-acid-forming fertilizers, H. L. COOK and S. D. CONNER** (*Jour. Amer. Soc. Agron.*, 28 (1936), No. 10, pp. 843-855, figs. 9).—In the

experiments here reported from the Indiana Experiment Station, it was thought that by using a procedure similar to that of the Neubauer test effects could be obtained more rapidly than by ordinary pot cultures. "A thickly planted crop was grown, then removed, and the soil thoroughly leached to imitate the effect of rainfall which might occur during several months in the field. New fertilizer was added, another crop grown, removed, and the soil leached. After five such treatments, one crop was grown without additional fertilization to get the residual effect. Then the soil was removed and mixed. . . . The following analyses were then made on soils from each treatment: The Jones acidity, Hopkins acidity, percentage saturation, and the pH in water and normal potassium chloride. Aliquots of the five leachings were taken, mixed, and analyzed for phosphorus, calcium, and magnesium." The soils used were a Miami and a Norfolk sandy loam. With the single exception of the Hopkins acidity value as determined for the Miami soil, "there is a significant similarity in the trend of results between various treatments on both soils." In the order of decreasing effectiveness for neutralizing acidity, the materials used were calcium silicate, fine dolomite, calcium carbonate, and tricalcium phosphate.

"There was in all cases better nitrification with the fine dolomite, the calcium carbonate, the tricalcium phosphate, and the calcium silicates than with the fertilizer alone or fertilizer neutralized with raw phosphate."

**Acidulated fertilizers for alkaline soils.** W. T. McGEORGE (*Calif. Citrogr.*, 21 (1936), No. 10, pp. 368, 384).—A note from the Arizona Experiment Station points out that such long-lived crops as fruit trees may be irremediably injured by the time they show any evidence of the harmful effects of an alkaline condition of the soil, and that "it appears logical to assume that if a fertilizer fortified with an acidulated organic base or 50 to 200 lb. sulfur per ton of fertilizer is used continuously for alkaline or calcareous soils, beginning at the time of planting, fruit trees should be able to obtain a normally balanced nutrient absorption from the soil at all times and not be continuously subjected to the stress of high soil pH." The author considers that the residual acidity of ordinary fertilizers is not likely to be sufficient to meet the needs of alkaline or calcareous soils. The advantages of residually acid fertilizers for such soils "would probably be more strongly manifested on fruit trees where the stress of alkalinity is continuous than in grains, truck crops, and other annual crops where the period of stress is short and nonaccumulative. Acidulated tankage or other acidulated organic material and sulfur are suggested as the most suitable acid fillers for acidified fertilizers. Where crops are subject to chlorosis such a fertilizer should be profitable, and it has the additional advantage that small amounts of zinc or iron salt, which are often deficient in such soils, could be added and as organic salts would be very available to the crop."

**The effect of sulfur and sulfuric acid upon the development of soil acidity at different depths.** G. S. FRAPS and J. F. FUDGE (*Jour. Amer. Soc. Agron.*, 28 (1936), No. 12, pp. 1012-1016).—At the Texas Experiment Station various quantities of sulfuric acid and sulfur were added to the surface 5 in. of a Lufkin fine sandy loam in 18-in. tiles, and the pH values of samples of the soils from different depths were determined at intervals over a 5-yr. period.

"Maximum acidity of the surface soil developed within 10 weeks, and that of the next 2 or 3 in. within 4 mo. after treatment. Acidity of all treated soils then slowly decreased. Penetration of acidity in excess of 2 or 3 in. occurred only in series in which the surface soil became so acid that no plant growth

could occur. The presence of free sulfuric acid and soluble salts in the soil solution was evident from the pH values secured. Increases in exchangeable hydrogen at the end of 5 yr. were equivalent to an average of about 60 percent of the acid added. The remainder of the acid must have reacted with non-exchange compounds in the soil, including bases made available by weathering. Single applications of acid to the surface soil is not a practical method for acidifying the subsoil for the control of plant diseases."

**Response of plants to boron, copper, and manganese, R. J. MUCKENHIEB** (*Jour. Amer. Soc. Agron.*, 28 (1936), No. 10, pp. 824-842, figs. 3).—Some of the results of an investigation reported from the Wisconsin Experiment Station are thus stated:

"In quartz sand cultures, lettuce was unable to continue normal growth or produce a second growth of leaves unless boron was added. Plants showing the typical boron-deficiency symptoms produced new leaves and resumed normal growth after boron was supplied. Milorganite (activated sludge containing some boron) made possible nearly normal growth and increased the boron content of the lettuce. Boric acid prevented the appearance of all deficiency symptoms and doubled the boron content of the plants. Pyrex glass was also a good source of boron. The application of kaolin to quartz sand cultures stimulated the growth of buckwheat and increased its content of manganese, but it inhibited seed production. Extraction of the sand and kaolin with dilute acid indicated that the manganese was obtained from the sand and not from the kaolin. The kaolin probably stimulated the feeding power of the buckwheat. The addition of manganese to the sand increased the yields appreciably.

"Applications of copper and manganese to peat soils in pot cultures increased the growth of onions and sweetclover and the manganese content of the leaves. Some evidence was obtained that copper and manganese affected the relative growth of bulbs and tops and the maturation of the plants as well as the rate of growth. Applications of copper, manganese, and zinc increased the yield of potatoes grown on peat soils in the field. The tubers of potatoes and the bulbs of onions grown on peat treated with copper appeared to be considerably better in quality than those not so treated. Extraction of the soils with dilute acid showed that the peats studied had not more than one-third as much readily soluble manganese per acre as mineral soils. On peat, on which applications of manganese gave no increase in yield, contained more manganese than other peats from the same tract on which onions and potatoes responded to manganese.

"These results suggest that manganese-deficient soils may be identified by means of chemical soil analysis."

**Manganese in New Jersey soils, A. W. BLAIR and A. L. PRINCE** (*Soil Sci.*, 42 (1936), No. 5, pp. 327-333).—The authors report from the New Jersey Experiment Stations an investigation of which the results show, in part, that "in general, the percentage of manganese is higher in soils from the northern part of the State than in those from the southern part, that is, those south of the line connecting New Brunswick and Trenton. . . .

"Long-time manure, fertilizer, and lime treatments do not appear to have influenced the manganese content of the soil. In soils from certain of the experimental plots a rather distinct difference was found between the manganese content of the surface soil, that is the A<sub>p</sub> horizon, and the A<sub>2</sub> and B horizons, the amount generally decreasing from A<sub>p</sub> to the B<sub>1</sub> horizon. . . .

"With slight exception, the manganese content of the crop decreased with increase in the amount of lime applied. In explanation of this, it is sug-

gested that with heavy liming the manganese is rendered less available. . . . The lowered intake of manganese by the plant does not appear to have a deleterious effect with reference to yield."

**Farm manure: Its value and conservation**, R. C. COLLISON and H. J. CONN (*Farm Res. [New York State Sta.]*, 3 (1937), No. 2, pp. 10, 13).—The unique value of farmyard manure in building up soil fertility and tilth is briefly discussed, and practical suggestions for handling such material in a way to avoid the loss of its most available constituents are made.

**Granulated fertilizers have distinct merit**, C. B. SAYRE (*Farm Res. [New York State Sta.]*, 3 (1937), No. 2, pp. 1, 5, 12).—The author points out various advantages of the granulated fertilizer over the pulverized form, such, for example, as less rapid loss or fixation in the soil of the more readily soluble components and the more even distribution by drilling machinery, etc. Trials with tomato plants as the test crop showed a very definite increase in the gain in crop weight from a given weight of fertilizer in the granular form.

**Profit from fertilizers**, H. V. GARNER ET AL. (London: Crosby Lockwood & Son, 1936, pp. 176, figs. 20).—"The object of this book is not so much to give a detailed account of fertilizers as to indicate that the use of fertilizers is profitable to the farmer." The book consists of a series of discussions, preceded by a foreword by Viscount Bledisloe and an introduction by H. C. Long. The topics and authors are as follows: The elements of plant nutrition—introduction, and compound and concentrated fertilizers and their use, both by H. C. Long; the nutritional requirement of crops—the classes of fertilizers, the distribution of fertilizers, note on the evaluation of manures, and composition, etc., of fertilizers, all by H. V. Garner; the manuring of permanent and temporary grass and hill pastures, both by R. G. Stapledon; the manuring of arable crops, by F. Rayns; the manuring of fruit crops, by T. Wallace; market garden and flower crops, by A. H. Hoare; and boron and plant disease.

**Inspection of fertilizers**, W. L. ADAMS and T. WRIGHT, JR. (*Rhode Island Sta. Ann. Fert. Circ.*, 1936, pp. 16).—In addition to the usual annual report of fertilizer analysis data, showing for the year 1936 an increased use of fertilizer containing 20 percent or more of plant food, the present circular records also the magnesium content, as the oxide, of such fertilizers as carried a guaranty for this element and a statement with respect to every fertilizer of which the analysis is reported showing it to be acid-forming or nonacid-forming.

Concerning the last-named information, the authors note that "It is not intended to condemn acid-forming fertilizers nor to place undue stress on this characteristic. Crop and soil conditions determine the need for the two types of mixtures, and both have a place. Where the acid-forming quality is not desired, however, dolomite or magnesian limestone can replace the relatively inert materials that are usually present as fillers, thus furnishing acid-neutralizing power and magnesium at a very low cost. In a region of acid soils such as are found in Rhode Island, the quantities of liming material so supplied will not be sufficient to take the place of the usual liming program, but should reduce materially the amounts of lime needed over a long period of time."

**[Work with fertilizers, West Virginia Station]** (*West Virginia Sta. Bul.* 278 (1936), pp. 22-24).—Data are reported under the headings lime and fertilizer for field and forage crops, alfalfa's response to degrees of liming (including the slow downward movement of lime in soil), and dolomitic limestone as filler.

**Inspection of agricultural lime products for the season of 1936**, H. D. HASKINS (*Massachusetts Sta. Control Ser. Bul.* 87 (1936), pp. 9).—This is the

twenty-fifth report on the inspection of agricultural lime products in Massachusetts. It gives the composition of the various products which have been sold in the State during the year. The mechanical analysis of the ground limestone products is also recorded.

## AGRICULTURAL BOTANY

**Illustrated polyglottic dictionary of plant names in Latin, Arabic, Armenian, English, French, German, Italian, and Turkish languages, including economic, medicinal, poisonous, and ornamental plants and common weeds.** A. K. BEDEVIAN (*Cairo: Argus & Papazian Presses, 1936, pp. XV+644+456+[12], pl. 1, figs. 1711*).—Part 1 comprises the dictionary proper, with scientific names alphabetically arranged and each followed by the plant family and the various common names, and appendixes relating to the Arabic transliteration system, Armenian and Turkish alphabets with keys to their pronunciation, the pronunciation of Latin words, a bibliography, and addenda and errata. In part 2, indexes of common names of plants are given for each of the eight languages included, and, for convenience in locating, the index for each language is on paper of a different color.

A preface by W. L. Balls is included.

**Methods in plant physiology.** W. E. LOOMIS and C. A. SHULL (*New York and London: McGraw-Hill Book Co., 1937, pp. XVIII+472, figs. 94*).—"This volume is an attempt to bring together material which will be useful alike to the instructor in biology or plant physiology, to the student in plant physiology, and to the research worker in plant physiology, farm crops, forestry, genetics, and horticulture."

In part 1, laboratory exercises, the subject matter is discussed under chapter headings of the water relations of plants, transpiration, plant nutrients, the role of diffusion in plants, colloidal phenomena in plants, photosynthesis, plant pigments, plant foods, respiration, plant enzymes, growth and movement, and growth-differentiation balance and growth correlation. Part 2, general methods, deals with general laboratory procedures, the chemical analysis of plant materials, the estimation of sugars, polysaccharides, nitrogen, and plant lipids, plant ash, physical measurements, and measurement and control of plant environment. A chapter on statistical methods, by G. W. Snedecor (pp. 383-416), is included.

An appendix contains 33 tables giving various quantitative data, formulas, etc. An index is provided.

**An introduction to the principles of plant physiology.** W. STILES (*London: Methuen & Co., 1936, pp. VIII+615, pls. 5, figs. 55*).—This text is addressed more particularly to university students. In it the purely biochemical details are introduced only insofar as reference to them has appeared essential to an understanding of the physiology of the plant. The subject matter is arranged under the general physiology of the cell, metabolism, the physiology of development, and irritability and movement. The literature references cover over 39 pages, and an index completes the work.

**Plant physiology: Experiments and observations on higher and lower plants, including bacteriology and hydrobiology (with plankton).** R. KOLKOWITZ (*Pflanzenphysiologie: Versuche und Beobachtungen an höheren und niederen Pflanzen einschliesslich Bakteriologie und Hydrobiologie mit Planktonkunde. Jena: Gustav Fischer, 1935, 3. ed., rev., pp. VI+310, pls. 14, figs. 175*).—Under part 1, phanerogams, the text discusses the essential elements and nutrient salts; chlorophyll and its function; diffusion, osmosis, and turgor; sugar, starch, reserve cellulose, and fatty oils; protein; water and air; respi-

ration; growth, movement, and irritability; and reproduction and inheritance. Part 2, cryptogams, treats of the plant groups from Myxomycetes and Schizomycetes through to the Pteridophyta and includes the ecology of bodies of water.

**Morphology of vascular plants: Lower groups (Psilophytales to Filicales),** A. J. EAMES (*New York and London: McGraw-Hill Book Co., 1936, pp. XVIII+433, figs. [216]*).—This textbook is intended to "make more readily available the important facts and theories in this field as known and interpreted today. . . . The viewpoint is that of broad comparative study, with the development of a natural classification and phylogenetic relationships as the goal." The order of arrangement follows that found by experience to be most satisfactory, though in general the more primitive forms are discussed first. A final general chapter takes up the plant body, alternation of generations, and the classification of vascular plants. Bibliographies are given at the ends of individual chapters, and a general bibliography and index complete the work.

**Practical photo-micrography,** J. E. BARNARD and F. V. WELCH (*New York: Longmans, Green & Co.; London: Edward Arnold & Co., 1936, 3. ed., pp. XII+352, pls. 23, figs. 121*).—A thorough discussion of the optical principles involved, types of instruments and illuminants available, and technical methods employed in photomicrography is brought up to date in this edition.

**An electrically heated needle for paraffin embedding,** A. C. FABERGÉ and L. LA COUR (*Science, 84 (1936), No. 2171, p. 142, fig. 1*).—A sewing needle in handle is heated by nichrome wire at low voltage.

[**Botanical studies by the Cornell Station**] ([*New York*] *Cornell Sta. Rpt. 1936, pp. 91, 92, 93, 96, 97*).—Progress reports are included on the following studies: Investigations on delayed photosynthesis in chlorophyll-bearing embryos of orchids, and other studies on orchid seed, by L. Knudson; influence of X-rays on the growth and metabolic processes in ferns, and effect of light and other factors on reproduction in certain fern prothallia, both by Knudson and H. T. Scofield; relation of manganese to plant growth, by E. F. Hopkins; the translocation of solutes in plants, by O. F. Curtis, I. H. Stuckey, E. M. Palmquist, and C. A. Moose; the production of tetraploid strains of teosinte, in cooperation with the U. S. Department of Agriculture, by L. F. Randolph; the oxygen supply and requirements of bacteria, by O. Rahn and C. P. Hegarty; and mitogenetic radiation, by Rahn and A. J. Ferguson.

**The plant cell: Lectures on normal and pathological cytomorphology and cytogenesis,** E. KÜSTER (*Die Pflanzenzelle: Vorlesungen über normale und pathologische Zytomorphologie und Zytogenese. Jena: Gustav Fischer, 1935, pp. XII+672, figs. 323*).—The text of this monograph is presented under the main headings of protoplasm, the cell nucleus, plastids, vacuoles, starch grains, crystals and other cell inclusions, the cell membrane, and the development of the cell (including sizes, forms and growth of cells, cell division, fusion of cells, regeneration, symbiosis, and cell age and death). Author and subject indexes complete the work.

**Investigations on the formation of the cell wall** [trans. title], K. HESS, C. TROGUS, and W. WERGIN (*Planta, Arch. Wiss. Bot., 25 (1936), No. 3, pp. 419-437, figs. 15*).—A study of the cytology and chemistry of cell wall development in cotton root hairs, oat coleoptiles, and young beech shoots is reported, using X-ray and polarization methods.

**The results of some attempts at the in vitro culture of isolated plant cells** [trans. title], L. MAROTTA (*Atti R. Accad. Naz. Lincei, 6. ser., Rend. Cl. Sci. Fis., Mat., e Nat., 21 (1935), No. 3, pp. 211-215*).—In numerous experiments car-

ried out on plants of widely separated groups, isolated cells in pure culture under sterile conditions have undergone survival, organization, and increase in size but never the phenomenon of cell division, since in no case have mitotic figures been observed.

**The concentration of solutes in sap and tissue, and the estimation of bound water.** T. G. MASON and E. PHILLIS (*Mem. Cotton Res. Sta., Trinidad, Ser. B, Physiol., No. 8 (1936), pp. 437-454*).—As there was no indication of the presence of bound water in the expressed sap, using the cryoscopic method, it is suggested that the discrepancy in the sap and tissue estimates of the concentration of solutes (sugar and chlorine) was due to the presence of bound water in the tissue. Studies of the estimation of bound water and its application to the estimation of sap-soluble materials are discussed. No evidence of the adsorption of sucrose or chlorine was obtained.

**The communication of the pneumatic systems of trees with the atmosphere.** D. T. MACDOUGAL (*Amer. Phil. Soc. Proc., 76 (1936), No. 6, pp. 823-845, fig. 1*).—The results of studies with an apparatus developed to measure the rate of streaming of atmospheric gases into the interior of living sections of woody stems established the presence of passages from the pneumatic system of trees across the cambium which were too small to allow streaming movements of watery solutions. The amount of suction necessary to initiate and maintain a flow of gases through these ducts varied from 5 to 30 mm of mercury in various trees. In some cases (e. g., *Salix*) sap-filled layers of wood were taken to affect the rate of streaming.

Variations in barometric pressure, in tensions of the meshwork of sap conduits, and in liberation of  $\text{CO}_2$  from living cells and woody walls are factors which may set up differences in pressure and initiate streaming movements. Movements of gases outwardly or inwardly through the cambium tend to equalize the pressure and composition of the pneumatic system and the outside air, thus constituting a means of ventilation.

The measurements of the rates of flow were made on young stems, while determinations of the composition of the gases of pneumatic systems were made on samples extracted from large or old trunks. The determination of rates of flow in the latter case would require different methods from those described.

**A study of certain factors influencing the movement of liquids in wood.** S. J. BUCKMAN, H. SCHMITZ, and R. A. GORTNER (In *Colloid Symposium Monograph*, VI, edited by H. B. WISER. Baltimore: Williams & Wilkins Co., 1935, pp. 103-120, figs. 7).—This is a contribution by the Minnesota Experiment Station, noted from another source (E. S. R., 75, p. 601).

**Some effects of light on the growth, flowering, rooting, and budding of various plants** [trans. title], P. CHOUARD (*Compt. Rend. Acad. Sci. [Paris], 202 (1936), No. 17, pp. 1454-1457*).—Experiments are briefly described on the effects of light intensity, duration, and quality on radish, spinach, bean, hybrid *Calceolaria*, peas, and *Brimeura* (ex *Hyacinthus*) *amethystina*. The advantages of supplementary illumination by an appropriate light, at optimum temperature, are stressed both in relation to precocity of flowering and to the processes of vegetative propagation.

**The study of the effect of blue-violet rays on photosynthesis.** R. H. DASTUR and R. J. MEHTA (*Ann. Bot. [London], 49 (1935), No. 196, pp. 809-821*).—The rate of photosynthesis was studied in the light of an incandescent oil lamp, a 1,500-w. gas-filled lamp, a "daylight" lamp, and a carbon arc lamp. The intensity of the blue-violet region in these four lamps increases in the order given, and the results of the study indicated that the photosynthetic rate also

increases in the same order. Thus the importance of the blue-violet region of the visible spectrum is demonstrated.

The photosynthetic activity of sunlight was highest in white light, intermediate in red light, and very feeble in blue-violet light. Both the red and the blue-violet regions are deemed necessary to normal photosynthetic activity, and even with white light the assimilation depends not only on the total energy content but also on the distribution of radiations of different wavelength.

**Effect of atmospheric humidity on rate of carbon fixation by plants,** J. W. MITCHELL (*Bot. Gaz.*, 98 (1936), No. 1, pp. 87-104, figs. 4).—The rates of carbon fixation by leaves of squash, wax bean, cabbage, *Pelargonium*, *Primula*, and tomato were not affected by a rapid decrease in the humidity of the ambient air or by prolonged exposure (from 15 to 20 hr.) to low humidity. Attached leaves of such plants remained turgid at moderate temperatures, even at extremely low humidities, but *Cineraria* leaves in some cases wilted and the loss of turgidity was always accompanied by a decreased rate of carbon fixation. Air temperatures above 30° C. retarded the rate of carbon fixation by *Pelargonium* leaves in both moist and dry air.

Under the test conditions, the maximum size of stomatal openings on tomato and *Pelargonium* generally occurred at relative humidities above 60 percent. Their size decreased with a lowering of air humidity, and the stomata usually appeared closed below 30 percent.

Carbon fixation was not greatly affected by wide variations in the size of stomatal openings. Leaves of tomato and *Pelargonium* absorbed CO<sub>2</sub> and accumulated carbohydrates in appreciable amounts even when the stomata appeared closed. That CO<sub>2</sub> was absorbed under these conditions was shown, since the amount fixed by leaves with apparently closed stomata was approximately equal to that fixed by the same leaves with open stomata, by the iodine test starch was found to accumulate in leaves exposed to relatively dry air with their stomata apparently closed, and the acid-hydrolyzable carbohydrates in *Pelargonium* leaves grown in relatively dry air increased approximately 41 percent in 6 hr., although their stomata appeared to be closed.

A bibliography of 20 titles is included.

**Control of atmospheric humidity in culture studies,** H. HOPP (*Bot. Gaz.*, 98 (1936), No. 1, pp. 25-44, figs. 11).—The quantitative method (easily set up and inexpensive) is recommended for small, closed chambers, and the qualitative method (simple and requiring little equipment and care) for both closed and fresh-air chambers. The physical control method by continuous vaporization is useful for a saturated atmosphere, but the additional apparatus required to secure relative humidities between 0 and 100 percent usually renders it inapplicable to culture studies. Intermittent vaporization proved most useful for large chambers, control being effected by a hygrostat and a humidifier, as described. Humidity control by physical methods was effective between 15° and 40° C.

**Activity of the vascular cambium in relation to wounding in the balsam poplar, *Populus balsamifera* L.,** A. B. BROWN (*Canad. Jour. Res.*, 15 (1937), No. 1, Sect. C, pp. 7-31, pl. 1, figs. 9).—In disbudded units, the greater the amount of living bark distal to the wound the greater was the development of local cambial activity in relation to the wound. Local wound cambial activity was further promoted by the presence of developing buds and leaves distal to the wound. Cambial activity in relation to wounding responded to gravity like normal cambium. In horizontally placed leader shoots, cambial activity was greater in relation to a wound on the upper side of the shoot than to a similar wound opposite on the lower side. It is suggested that a hormone in the living

bark and also produced by developing buds and leaves is involved in local wound cambial activity. Probably this hormone is identical with that promoting normal cambial activity.

It is also suggested that a wound substance capable of promoting itself only by cell division is involved in local wound cambial activity, and the amount produced is apparently proportional to the extent of dying of cells of the bark after wounding. From the lower edge of a complete ring a very feeble basipetal gradient of cambial activity arises in which differentiation to form vessels and fibers fails to occur, though a few tracheids may be found. This is believed to be the first report of such behavior, and it is interpreted to result from stimulation of the cambial layers by the wound substance alone. Local cambial activity above a complete ring and in relation to bridged wounds involves differentiation of more or less typical vessels and fibers, interpreted to result from interaction between the wound substance and the cambial hormone traveling basipetally in the living bark cells. The absence or feebleness of development of cambial activity at certain points in relation to bridged wounds, in contrast to greater development at other points where the concentration of cambial hormone is presumed to be less, is interpreted to result from a lack or low concentration of wound substance acting as a limiting factor.

**Germination behavior of some California plants, N. T. MIROV** (*Ecology*, 17 (1936), No. 4, pp. 667-672).—In this contribution by the California Experiment Station, the germination experiments (covering over 300 species of 64 families) are considered to justify the following conclusions: There is no consistent relation between systematic position and germination behavior, but certain tendencies within families are clearly indicated. There is a definite correlation between germination behavior of species and altitudinal distribution, failure to germinate owing to seed coat conditions being found mostly at low elevations. The need for prolonged low temperature before germination, supplemented by abundant moisture, was most common in seeds grown at high elevations, though such conditions were in many cases necessary for seeds of plants of medium and low elevations.

In annuals, when delayed germination occurred it was due to seed coat conditions alone. In herbaceous perennials it was due either to the need for afterripening at low temperatures or to seed coat conditions. Woody perennials were the most complex group, delayed germination being due to seed coat conditions, need for afterripening at low temperatures, or to a combination of both.

**Comparative anatomy of the seeds of cottons and other malvaceous plants, I, II, R. G. REEVES** (*Amer. Jour. Bot.*, 23 (1936), Nos. 4, pp. 291-296, figs. 18; 6, pp. 394-405, figs. 52).—This is a contribution by the Texas Experiment Station, part 1 dealing with the Melveae and Ureneae, and part 2 with various species of *Gossypium* and related species.

**Further studies on transport in the cotton plant, V, VI, T. G. MASON and E. PHILLIS** (*Mem. Cotton Res. Sta., Trinidad, Ser. B, Physiol.*, Nos. 8 (1936), pp. 455-499, figs. 20; 9 (1936), pp. 679-697, figs. 6).—Two papers are included:

**V. Oxygen supply and the activation of diffusion.**—As a result of this study "it is suggested that the mechanism activating diffusion consists in some special organization in the cytoplasm, maintained by metabolic energy, whereby the resistance to solute movement is so reduced that materials diffuse in the sieve tube at rates comparable with those in a gas."

**VI. Interchange between the tissues of the corolla.**—"The reversal of the direction of transport in the corolla is explained as follows: Solutes move between the phloem and the parenchyma between the veins to maintain the

distribution determined by the relative solvent capacities of the two tissues. Continued movement from the phloem into the parenchyma is ensured during development by the maintenance of low concentrations as a result of utilization and of the intake of growth water. After anthesis the cessation of utilization would lead to a cessation of import. With the onset of protoplasmic decomposition and the drying out of the tissues, the concentration in the parenchyma rises and solutes move back into the phloem. If the solvent capacity of the parenchyma declines with age, another factor promoting export from the parenchyma would be introduced."

**Seasonal changes in the carbohydrates of the wheat plant, H. R. BARNELL** (*New Phytol.*, 35 (1936), No. 3, pp. 229-266, figs. 9).—The percentage amounts of various carbohydrates in the Rivets and Wilhelmina wheat varieties collected at sunrise through two seasons indicated well-defined developmental drifts. During winter and early spring the drifts of some of the carbohydrates (particularly sugars) were somewhat obscured by environmentally induced effects, but it was possible to obtain a clear picture of the drifts throughout the season and to note the nature of the complications caused by weather factors. These are discussed in detail.

The sugars occurred in the following order of percentage amounts: Sucrose, glucose, and fructose. Both varieties responded to low temperatures by increases in sugar concentration (particularly sucrose). Starch was absent from stems and leaves at all times, but glucose- and pentose-yielding polysaccharides were present. Starch was definitely formed only in the ears. There was practically no significant difference in the carbohydrate contents of the two varieties. Wilhelmina was more sensitive in its sucrose reaction to low temperatures than Rivets. The ears of Wilhelmina started to ripen more rapidly than those of Rivets, but the latter, after a lag period, ripened more rapidly and tended to catch up.

**The chemotropism of the plant root, I, II** [trans. title] (*Biochem. Ztschr.*, 286 (1936), No. 1-2, pp. 110-127, figs. 2).—The following parts are included:

I. *The chemotropic stimulation of roots by mineral salts*, B. Niklewski and J. Duda (pp. 110-119).—In the tests reported the excitant was incorporated in a small agar block placed beside the root tips of *Sinapis alba*. After from 4 to 5 hr. of action the direction of growth of the root, overcoming the geotropic stimulus, became altered. The curvatures were almost exclusively positive, and the few cases of negative bending could be attributed to pathological causes. The phosphate ion had a strongly positive action and the  $\text{NO}_3$  ion a weaker effect. In addition to potassium, the cations acting most strongly were  $\text{Hg}^{++}$ ,  $\text{Al}^{+++}$ ,  $\text{Fe}^{+++}$ , and  $\text{UO}_2^{++}$ . Not only the electrolytes but various organic substances (e. g., eosin and methyl violet) exhibited a strong chemotropic action on the root tip.

II. *The chemotropic stimulation of roots by colloidal substances*, B. Niklewski, H. Brodowska, M. Dydo, and M. Kahl (pp. 120-127).—The results given indicate that not only molecular but also colloidal solutions may induce chemotropic stimulation. A quartz suspension with a maximum particle size of 0.002 mm induced no chemotropic reaction, but colloidal solutions of gold, silver, ferrous hydroxide, copper, and sulfide of arsenic, with size of particles below 100  $\text{m}\mu$ , called forth very distinct chemotropic curvatures. Solutions of mastic and of gamboge reacted similarly, and strong chemotropic stimulations were induced by the humus colloids contained in stable manure. As soon as the solutions coagulated (determined for gold and silver solutions) they lost this power. On the contrary, the hydrosols of agar, albumin, and edestin, the particles of which are invisible even submicroscopically, called forth no chemotropic reac-

tions. Although crude egg white causes these reactions, their origin is explained on the basis of various substances other than the albumin contained therein.

The basis of this type of stimulation by colloidal substances is believed to lie in the impact of the particles on the root cells rather than in the penetration of the cells, as is assumed for the ions of molecular solutions. However, only particles of a certain size act as chemotropic stimuli.

**Investigations on the action of the natural growth-promoting substances and of  $\beta$ -indolylacetic acid on the metabolism of plants** [trans. title], G. FRIEDRICH (*Planta, Arch. Wiss. Bot.*, 25 (1936), No. 4, pp. 607-647, fig. 1).—The experiments were performed on *Helianthus*.

**The conduction of growth-promoting substances in plants, I, II** [trans. title], F. LAIBACH and O. FISCHNICH (*Planta, Arch. Wiss. Bot.*, 25 (1936), No. 4, pp. 648-659, figs. 11; 26 (1936), No. 1, pp. 81-89, figs. 5).—The first paper describes tests carried out with red coleus and cucumber. The second describes a method for determining the rate of transmission of  $\beta$ -indolylacetic acid (heteroauxin) in intact plants (*Cucumis sativus*).

**Auxin and correlative inhibition**, B. LE FANU (*New Phytol.*, 35 (1936), No. 3, pp. 205-220, figs. 2).—Axillary buds of pea (*Pisum sativum*) on single-node stem cuttings and the growth of young stems were inhibited when the ends were placed in heteroauxin solution. Growth of young internodes was also inhibited by lanolin containing heteroauxin placed on the stem in a position morphologically below them, although their growth was accelerated by the same treatment applied above. Leaves protected a stem against heteroauxin inhibition. Buds of cuttings were inhibited by heteroauxin in gelatin applied to the cut ends of the stems above or below them, but more strongly when applied above. Little or no auxin was present in an inhibited shoot. A completely inhibited shoot transported auxin only feebly, if at all, in either direction.

It is concluded that inhibition of lateral buds and shoots is probably a secondary process originating from some positive primary process promoted by auxin in the inhibiting shoot.

**Leaf movements under the influence of artificially applied growth substances** [trans. title], F. LAIBACH and O. FISCHNICH (*Biol. Zentbl.*, 56 (1936), Nos. 1-2, pp. 62-68, figs. 3).—These tests were carried out in the greenhouse with coleus and tomato plants subjected to the action of  $\beta$ -indolylacetic acid used as a paste and with lanolin alone applied in the controls.

**Vitamin B<sub>1</sub> and the growth of excised tomato roots**, W. J. ROBBINS and M. A. BARTLEY (*Science*, 85 (1937), No. 2201, pp. 246, 247).—Work at the University of Missouri showed that excised tomato roots will grow indefinitely in White's solution (E. S. R., 72, p. 185) where the yeast is replaced by natural crystalline vitamin B<sub>1</sub> Merck or by synthetic B<sub>1</sub> Merck, the first-mentioned vitamin being effective at the great dilution of  $1 \times 10^{-4} \gamma$  in 50 cc. It is suggested that normally the tomato root depends on the top part of the plant not only for carbohydrate but also for vitamin B<sub>1</sub>.

**Can the Klebs theory relative to the dependence of blossom formation on the chemical composition of the plant be maintained?** [trans. title] H. KNODEL (*Ztschr. Bot.*, 29 (1936), No. 10-11, pp. 499-501, figs. 12).—This is a theoretical and analytical study and review, with a literature list of 54 titles. The experiments conducted with oats, spinach, lettuce, rudbeckia, and chrysanthemum failed to indicate any influence of the nitrogen: sugar ratio or of the phosphorus picture on blossom formation. The relationship of organic to inorganic substances depended on the intake of light during development, but no

characteristic relationship to the time of formation of the blossom anlage was found.

**The mineral absorption of higher plants as function of a correlation between inner and outer factors** [trans. title], O. SCHMIDT (*Ztschr. Bot.*, 30 (1936), No. 7-8, pp. 289-334, figs. 14).—The experiments were performed on *Sanchezia nobilis*, *Helianthus annuus*, *Impatiens* spp., *Tropacolum aduncum*, *Zea mays*, *Sicyos angulata*, *Cyclanthera* spp., and *Cucumis sativus*. A bibliography of 24 references is included.

**Comparative content in sulfur and phosphorus of plants grown on the same soil** [trans. title], G. BEERTRAND and L. SILBERSTEIN (*Bul. Soc. Chim. France, Mém.*, 5. ser., 3 (1936), No. 4, pp. 625-628).—This paper gives data essentially the same as previously noted (E. S. R., 75, p. 317).

**Semisolid media for cultivation and identification of the sporulating anaerobes**, R. S. SPRAY (*Jour. Bact.*, 32 (1936), No. 2, pp. 135-155).—This is a contribution by West Virginia University.

**The indol tolerance of certain strains of the colon-aerogenes group**, R. L. FRANCE (*Jour. Bact.*, 32 (1936), No. 2, pp. 211-214).—This is a contribution by the Massachusetts Experiment Station.

**Essential growth factors for propionic acid bacteria, I, II** (*Jour. Bact.*, 32 (1936), No. 2, pp. 157-174, figs. 4).—These two papers from the University of Wisconsin are entitled, respectively, Sources and Fractionation, by E. L. Tatum, W. H. Peterson, and E. B. Fred (pp. 157-166), and Nature of the Neuberger Precipitate Fraction of Potato: Replacement by Ammonium Sulphate or by Certain Amino Acids, by E. L. Tatum, H. G. Wood, and W. H. Peterson (pp. 167-174).

**Root nodule bacteria of some tropical leguminous plants.—I, Cross-inoculation studies with *Vigna sinensis* L., O. N. and E. K. ALLEN** (*Soil Sci.*, 42 (1936), No. 1, pp. 61-74, pls. 2).—This report by the Hawaiian Pineapple Producers' Experiment Station presents the results of observations on nodule formation on various leguminous plants and cross-inoculation tests with these plant species. The versatility of the now so-called cowpea group is further emphasized by the addition of various distantly related leguminous plants as a result of rigidly controlled plant inoculation tests (34 species of the Mimosoideae, 3 of the Caesalpinioideae, and 54 of the Papilionoideae). The present state of the cowpea group is briefly discussed.

**The abnormal structure induced in nodules on lucerne (*Medicago sativa* L.) by the supply of sodium nitrate to the host plant**, H. G. THORNTON and J. E. RUDORF (*Roy. Soc. [London], Proc., Ser. B*, 120 (1936), No. 817, pp. 240-252, pls. 3, figs. 3).—"Microtome sections of the nodules revealed the following abnormalities which were associated with the supply of nitrate to the host plant: (1) The cell walls of the distal cap were very much thickened, the cell wall material often projecting into the cells in the form of concretione-like lumps. These thickened walls and the lumps gave the same microchemical reactions as did the thin cell walls of the normal tissue. The cell contents were usually reduced and the nuclei greatly shrunken. (2) The endodermis that surrounds the central tissue of the nodule and also that which ensheathes the vascular strands were abnormally thickened by a deposition throughout the cell walls of material giving the suberin reaction with scharlach R. (3) There was an increased tendency towards necrotic decay of the central bacterial tissue, and where this did not occur the cell contents were usually much reduced. (4) In the younger portions of the bacterial tissue, the bacteria occur principally in the coccus stage of their life cycle, a stage usually associated with food deficiency."

## GENETICS

The principles of heredity, L. H. SNYDER (*Boston and London: D. C. Heath & Co., [1935], pp. XIII+385, [pls. 3], figs. [150]*).—A textbook presenting the principles of genetics, with special reference to animals and man.

A cytogenetic study of a chromosome fragment in maize, M. M. RHOADES (*Genetics, 21 (1936), No. 5, pp. 491-502, figs. 5*).—A corn plant intermediate in appearance between the trisomic and disomic individuals appeared in the progeny of a plant trisomic for chromosome V in cooperative studies by the Iowa Experiment Station and the U. S. Department of Agriculture, and carried a fragment of chromosome V besides the normal complement of 20 chromosomes. The fragment consisted of the entire short arm of chromosome V with a terminal spindle fiber insertion region.

The fragment chromosome was associated with the two normal chromosomes in about one-half the cells. Segregation of the three members of the trivalent groups was not random, but in such a manner that the fragment chromosome usually accompanied a normal when it passed to a pole. The spindle fiber insertion region of the fragment chromosome was observed to be split or double in cells where it was lying free in the nucleus as a univalent. The equational split into two chromatids was clearly evident. The  $V_3$ ,  $Y_3$ ,  $Pr$ ,  $V_{12}$ ,  $V_8$ , and  $Bt_1$  loci were located in the long arm of chromosome V, while the  $Bm_1$  and  $A_1$  loci were located in the short arm of the chromosome. Pollen hyperploid for the fragment chromosome occasionally functioned in competition with haploid pollen. Crossing over in certain regions seemed more frequent in fragment plants than in diploids.

The histological background for dwarfism in *Zea mays*, L. B. ABBE (*Amer. Phil. Soc. Proc., 76 (1936), No. 5, pp. 743-747, pls. 2, figs. 4*).—Measurements made on 18 cultures segregating for dwarf or dwarflike types of corn, including 9 dwarf types grown at Cornell University, and on other dwarf types and their normal sibs provided from other sources, included length of tassel and of internodes; diameters (at right angles) of the upper, middle, and lower part of each third internode; lengths of leaf sheaths and blades; and leaf blade widths at various points. Normal and dwarf plants are compared graphically and discussed. Although generalizations are not attempted, it is pointed out that a suggestive relation between cell and gross internode diameters was apparent in some cases.

Cytological studies on the peanut, *Arachis*.—II, Chromosome number, morphology, and behavior, and their application to the problem of the origin of the cultivated forms, L. HUSTED (*Cytologia, 7 (1936), No. 3, pp. 396-423, figs. 56*).—Further studies are reported (*E. S. R., 71, p. 758*).

Consideration of the basic chromosome numbers present in the legume family indicate that *A. hypogaea* is a polyploid species. The chromosome number of 115 plants representing 33 species, varieties, lines, and  $F_1$ ,  $F_2$ , and  $F_3$  varietal hybrids is reported as 20 ( $n$ ) or 40 ( $2n$ ). An exceptional plant contained 41 somatic chromosomes and a small fragment. The 116 plants examined showed the presence of 2 chromosomes morphologically distinguishable from the others because of their smaller size. One strain of Spanish, 1 of runner, and 9  $F_3$  plants of a Spanish  $\times$  runner cross showed the presence of chromosome pair "A" and a second pair, "B", the chromosomes of which possess a subterminal attachment constriction and a conspicuous secondary constriction.

In the cultivated peanut (*A. hypogaea*), chromosome association during meiosis in varieties and varietal hybrids is usually seen as 20 normal bivalents. Other configurations such as trivalents, quadrivalents, quinquevalents,

sexivalents, and an association of 10 chromosomes are occasionally formed. It appears to be a species in which deviations from the 40 somatic number seldom occur. The origin of bunch and runner type forms of the commercial peanut is discussed in the light of the cytological results. In that their chromosome number, morphology, and behavior are essentially similar, and the chromosomes of these two peanut types are seen to be homologous each to each notwithstanding possible minor changes, it is concluded that they, as well as *A. nambyquarae* and *A. rasteiro*, have been derived from a common origin.

**Studies on the inheritance of carotene in carrots,** S. L. EMSWELLER, P. C. BURRELL, and H. A. BORTHWICK (*Amer. Soc. Hort. Sci. Proc.*, 32 (1935), pp. 508-511, fig. 1).—Among interesting findings in this study, conducted by the California Experiment Station at Davis, were that there is much more carotene in the phloem than in the xylem of the roots and the amount of carotene is greater in both the xylem and phloem at the top than at the base of the root. Apparently carotene accumulates rapidly at the top until a limit is reached, after which accumulation progresses downward. A high correlation was noted between the color of the tissue and its carotene content. Colorimeter readings on the total extracted pigments before the separation of carotene and xanthophyll was effected were correlated very consistently with carotene content. In comparing the carotene content of a commercial Danvers stock with a strain inbred for four generations, it was found that the inbred line was much less variable. Notable differences were found in the carotene content of different inbred lines.

**The inheritance of a green flowered variation in *Cucumis sativus*,** A. E. HUTCHINS (*Amer. Soc. Hort. Sci. Proc.*, 32 (1935), p. 513).—Attempts to self-fertilize a green flowered variant characterized by hypertrophied stamens in the male flowers and larger ovaries and stigmas in the female flowers led to no fruits with seed. No success was secured in crosses in which the green variant was used as the ovule parent, but there was good success when the green variant was used as the pollen parent and other inbred lines as the ovule parent. The results indicate that the green flower is inherited as a recessive character whose expression is due to a one-factor difference.

**The interaction of the blue and green color factors in Hubbard squash,** A. E. HUTCHINS (*Amer. Soc. Hort. Sci. Proc.*, 32 (1935), p. 514).—Crosses made at the Minnesota Experiment Station in 1932 between self-fertilized lines of Green and Blue Hubbard squash yielded F<sub>1</sub> progeny of light green color intermediate between the two parents. In the F<sub>2</sub> and backcross populations, the size and shape of fruits ranged between those of the two parents. Green color was apparently partially dominant to blue.

**The uniform fruit color gene in the tomato,** A. F. YEAGER (*Amer. Soc. Hort. Sci. Proc.*, 32 (1935), p. 512).—Stating that the factor of uniform fruit color is a simple recessive not possessed by any important tomato variety, the author discusses results of crosses at the North Dakota Experiment Station of the Bison tomato with an unnamed variety possessing the uniform fruit color gene. Certain seedlings were obtained which were characterized by great earliness, small determinate vines, red flesh, good size, uniform fruit color, and apparently unusual resistance to heat and drought.

**Apple breeding: An example of parental prepotency in two progenies of the Delicious apple,** H. L. LANTZ (*Amer. Soc. Hort. Sci. Proc.*, 32 (1935), pp. 10-12).—Observations by the Iowa Experiment Station on the progenies of two apple crosses—Antonovka × Delicious and Black Annette × Delicious—produced in the same year and grown under comparable conditions, showed

striking contrasts. In the young trees, the 134 trees of the first cross included 84.4 percent of very good and good grades, whereas the 94 trees of the second cross contained only 17 percent of good and no very good trees. Other progenies of Antonovka crossed with King David, Ashton, Grimes Golden, and Jonathan also showed marked vigor, indicating that Antonovka carries a group of dominant growth genes and approaches a homozygous condition for factors producing vigorous growth. Black Annette  $\times$  Anisim produced poor trees indicating that Black Annette represents a genetic complex lacking in a capacity to produce strong growth factors in the progeny.

**Hybridization of animals.** A. S. SEREBROVSKIĬ (*Gibridizatsiia zhivotnykh. Moskva: Gosud. Izdatel., 1935, pp. 290, pls. 4, figs. 99*).—Results are presented in this Russian publication of species crosses produced in animals, the comparative fertility of hybrids, and the use of methods of artificial insemination in bringing about crosses.

**The genetics of cattle.**—I, A survey of the literature upon the inheritance of milking capacity, A. D. BUCHANAN SMITH and O. J. ROBISON (In *Bibliographia Genetica. 's Gravenhage (The Hague): Martinus Nijhoff, 1933, vol. 10, pp. 1-104*).—A review is presented of research dealing with the inheritance of milk production, persistency and milk composition in dairy cattle as related to conformation, color, progeny testing, inbreeding, relative importance of the two parents, and the number of genetic factors involved. On account of the differences expressed by numerous investigators as to the mode of inheritance of production, it was impossible to come to a single conclusion. Mention is also made of the influence of many environmental and nutritional factors.

**Contingent relations between blood groups and milk production in cattle** [trans. title], C. KRONACHER and F. HOGREVE (*Ztschr. Zücht., Reihe B, Tierzücht. u. Züchtungsbiol., 35 (1936), No. 1, pp. 89-93*).—Study of the milk and fat production records of 111 cows in 3 herds with reference to the 9 blood types showed that the production of those in the Oo group was below the average in all three herds. There was some tendency in two of the herds for cows having different serum agglutinating properties to show relatively high production in comparison with the rest of the herd.

**Horn inheritance in Galloway-Holstein cattle crosses,** W. T. WHITE and H. L. IBSEN (*Jour. Genet., 32 (1936), No. 1, pp. 33-49*).—In reciprocal crosses of Galloway and Holstein cattle at the Alaska Experiment Station, there were produced in the F<sub>1</sub> generation 12 polled females, 8 polled males, and 5 males with scurs. None of the 29 F<sub>2</sub> animals and only 1 F<sub>2</sub> had scurs. To account for these results and those obtained by other workers, a hypothesis is presented from the Kansas Experiment Station explaining the inheritance of horns and scurs.

"All cattle are assumed to be homozygous for the horned gene, *H*. Polled animals carry a dominant gene, *P*, which is completely dominant to *p* (absence of polled) and also completely epistatic in both sexes to *H*. Two other factors are postulated, *Ha* ("African" horns) and *Sc* (scurred). The latter is sex-limited to the extent that in both the heterozygous and the homozygous condition it is epistatic to *P* in males, while it is epistatic only in those females that are homozygous for the gene. A similar relationship applies to *Ha*, except that it has not yet been determined whether or not homozygous *Ha* females carrying *P* are horned. In nonpolled (*pp*) animals *H* is epistatic to *Sc* in both sexes and apparently is epistatic to *Ha*, although it is quite conceivable that *H* and *Ha* each has a modifying effect on the other, making the epistasy incomplete."

The operation of these factors in matings is discussed in connection with the results of other investigators and the appearance of genes *Ha* and *Sc* in Hereford cattle and mutations of these and the other genes. Evidently the gene *P* is not linked with the black or self-color genes.

The silver gray color in Indian cattle, A. O. RHOD (Jour. Heredity, 27 (1936), No. 3, pp. 113-118, figs. 4).—Study of the Guzarat and Nellore breeds of Indian cattle in Brazil showed that the hair of these cattle is characterized by a nonpigmented tip, producing a silver gray effect in the coat pattern. Based on crosses of Guzarats with Holsteins, it appears that the self-pattern of the Guzarat is dominant to Holstein spotting, but the total pigmented hair (*Tp*) of the Holstein was dominant to the tipped or bicolored condition. The width of the tip is assumed to be controlled by plus and minus modifiers. The tipped condition of the hair is characteristic of the Guzarat, Nellore, Scindl, Jersey, and Brown Swiss cattle, while the Angus, Holstein, Red Polled, and Shorthorn are characterized by the unicolored type of hair.

A case of extreme sex-modification in an adult bovine free-martin, A. BUYSE (Anat. Rec., 66 (1936), No. 1, pp. 43-58, figs. 3).—Modification in the sexual organs of a 30-month-old free-martin, born with 2 males in a set of triplets, are described. A penislike structure 26 cm long was in a highly contorted condition ventral to the vestibule and urinogenital sinus and terminated in a large glans penis. Germ cells were absent in the gonads, which contained seminiferous tubules, undifferentiated medullary cords, and rete. The vasa deferentia emptied into the urogenital sinus. There were well-developed seminal vesicles but no trace of a uterus or a vagina. The males are considered as the reason for the extreme sex reversal in the female.

The experiments of T. H. RICHES concerning the production of monsters in cattle, R. C. PUNNETT (Jour. Genet., 32 (1936), No. 1, pp. 65-72).—To ascertain if the lethal monsters occurring in Dexter and Telemark cattle are due to the same or different genes, a Telemark bull, carrying the recessive lethal of the breed, was mated to Dexter cows. There were produced 24 calves and 1 mummy, but none were of the monster type. It is concluded from these results that the monsters in the two breeds are due to different genetic factors. Confirming this, among 11  $F_1$  progeny there were produced 3 Dexter-type and 1 Telemark-type monsters.

The data on the structure of the testes of hybrids of yak and cattle, A. I. ZUITIN and V. V. IVANOVA (Compt. Rend. (Dok.) Acad. Sci. U. R. S. S., n. ser., 4 (1936), No. 2, pp. 75-77).—Hybrid males between yaks and cattle exhibited similar disturbances in germ cell formation in those that were produced in the first cross and by backcrossing  $F_1$  females to bulls. Spermatogenesis reached a more advanced stage in a backcross produced by mating an  $F_1$  female to a full-blooded yak. Mature sperm appeared in small amounts, but mobility and fertility was not determined.

On the chromosomes of the yak (*Poephogus grunniens* L.), A. I. ZUITIN (Compt. Rend. (Dok.) Acad. Sci. U. R. S. S., n. ser., 4 (1935), No. 1-2, pp. 81-83, fig. 1).—The diploid number of chromosomes in the yak was found to be 64, with the Y chromosome presumably the smallest. The fact that cattle have 60 chromosomes is suggested as the reason why males of yak-cattle crosses are sterile.

The inheritance of swine colors in race crosses [trans. title], J. SCHMIDT (Forschungsdienst, 1 (1936), No. 3, pp. 205-217).—A summary of color inheritance in breed crosses.

Contribution to inheritance in swine in the first cross [trans. title], D. DSCHAPARIDSE (Ztschr. Zücht., Reihe B, Tierzücht. u. Züchtungsbiol., 34

(1936), No. 3, pp. 335-347, figs. 8).—Comparison of the characters of Hannover-Braunschweigisches Landschwein and White German Edelschwein and the crosses between them showed that the sow was solely responsible for the duration of the gestation period and the size of the litter, and the boar had no influence on them. However, the weight of the pigs was intermediate between the weights of the purebreds. Mortality to 28 days was less in cross-breds than in purebreds although size and growth rate were intermediate. The white color was generally, although not completely, dominant.

**How far is an increased lard production through crossing possible?** [trans. title], C. KRONACHER and J. KLIESCH (*Ztschr. Zücht., Reihe B, Tierzücht. u. Züchtungsbiol.*, 34 (1936), No. 3, pp. 327-333).—Dressing percentages and fat yields of cross-bred and purebred swine are presented. The cross-breds grew faster, but the fat percentages at the same weights were higher in purebreds.

**A study of the fossil horse remains from the upper Pliocene of Idaho,** C. L. GAZIN (*U. S. Natl. Mus. Proc.*, 83 (1936), No. 2985, pp. 281-320, pls. 11, figs. 4).—Detailed descriptions are given of the bones from the fossil horse remains found in southern Idaho.

**An hereditary lethal for localized motor and preganglionic neurones with a resulting paralysis in the dog,** C. R. STOCKARD (*Amer. Jour. Anat.*, 59 (1936), No. 1, pp. 1-53, pls. 10, figs. 3).—A study is reported of a condition in several breeds of large dogs, involving a more or less pronounced weakness in the posterior extremities resulting in faulty gait or even in inability to stand. The condition develops after a few months of age and, in many cases, the dog compensates for it by the use of other muscles. From nine cross matings of normal Great Danes and St. Bernards, 57 puppies were raised to 3 mo. of age and all but 3 or 4 exhibited the condition. Among the 66 F<sub>2</sub> progeny raised to 3 mo. of age, only about 20 showed symptoms of the hind leg paralysis. However, the birth to 3 mo. of age mortality was 68 percent in this group. It is suggested that the paralysis is due to a complex of three dominant genes, two of which were contributed by one of the parent breeds and one by the other.

Crosses of bloodhounds with Great Danes produced F<sub>1</sub>s with somewhat hyperextended straight legs. A high percentage of paralysis occurred among the F<sub>2</sub>s that survived to 3 mo. of age. No other dogs derived from many crosses have shown the same type of paralysis. Pathological aspects of the condition involving death of certain motor and preganglionic, sympathetic neurones in the lateral and anterior horns of the lumbar region of the spinal cord are discussed.

**On the genetics of the spotted pattern of the guinea pig,** S. WRIGHT and H. B. CHASE (*Genetics*, 21 (1936), No. 6, pp. 759-787, figs. 2).—An analysis of white spotting in the guinea pig is reported based on crosses of inbred strains. Twenty-three grades of spotting were set up, ranging from complete self to complete white. The inbred strains showed a high degree of variability as regards the spotting expressed, and the F<sub>1</sub> and F<sub>2</sub> progenies exhibiting similar distributions suggested the operation of at least four or five pairs of segregating factors to explain the differences between the inbred strains. There were postulated a major pair of alleles *S* and *s* in which there was incomplete dominance, with *s* tending toward white. By the action of modifying factors, *SS* animals may show traces of white. *Ss* animals range from self-colored up to 95 percent white, and *ss* range from self-white to only a trace of white or are perhaps self-colored. An enormous amount of nongenetic variability was found to exist. Within strains correlations between parents and offspring and litters were very low. Only 42 percent of the variance in spotting was genetic

in a stock in which no matings as close as second cousins were made. Sex differences accounted for 2 to 3 percent of the variance in the random-bred and isogenic strains, respectively. Females had more white than males. A discussion is given of the interpretations of other authors regarding spotting in the guinea pig.

**The association between color and size in mice**, C. V. GREEN (*Amer. Nat.*, 69 (1935), No. 725, pp. 635-638).—In discussing the results presented by Feldman (*E. S. R.*, 73, p. 767) on body weights of heterozygous black and homozygous brown mice, it is suggested that linkage of the *b* gene with genes for growth offers an explanation better than that based on a direct influence of the *b* gene on growth.

**Multiple lethal genes in the mouse**, C. V. GREEN (*Jour. Heredity*, 27 (1936), No. 5, pp. 181, 182, fig. 1).—An account is given of the production of a mouse heterozygous for the four dominant mutations, yellow, brachyuric, white spotting, and naked. In crossing the yellow brachyuric females with a dominant spotted naked male, there were produced 22 progeny, representing 14 of the 16 expected classes. It is evident that these lethals in the mouse are not cumulative in action, although any one in the homozygous condition is lethal. The four doses of different mutations did not cause the death of the zygote.

**Grey-lethal, a new mutation in the house mouse**, H. GRÜNEBERG (*Jour. Heredity*, 27 (1936), No. 3, pp. 105-109, figs. 6).—The operation of a new lethal gene in the house mouse is described. Homozygous animals have a pure gray fur without a trace of yellow. At birth, gray-lethals are slightly underweight. The rate of growth slows during the second week and the animal dies. There is no eruption of teeth, and bone formation is abnormal. Death is not due to starvation because of inability to eat solid food, as the gray-lethals die under 42 days of age even when receiving liquid food. Histological study of the bones showed that the spongiosa, once formed, persists permanently, whereas normally the initial spicules are later destroyed.

**Some linkage tests with wavy mice**, H. GRÜNEBERG (*Jour. Genet.*, 32 (1936), No. 1, pp. 1-3).—Linkage tests conducted at the University College, London, showed independent segregation of the waved gene (*wr*<sub>1</sub>) in mice and the factors for pinkeye dilution (*p*<sub>1</sub>), nonagouti (*a*), brown (*b*), and blue dilution (*d*).

**Linkage studies of waved coat in the house mouse**, S. O. BURHOE (*Jour. Heredity*, 27 (1936), No. 3, pp. 119, 120).—Linkage tests showed waved<sub>1</sub> to be inherited independently of the genes for agouti, albinism, short ear, leaden, rodless, piebald, anemia, waltzing, dominant spotting, dwarf, and naked. It is concluded that *w*<sub>1</sub> may be considered as the marker of another chromosome.

**A geneticist studies leukemia**, E. C. MACDOWELL (*Sci. Mo.*, 42 (1936), No. 2, pp. 99-110, figs. 8).—A discussion of leukemia in mice, with special reference to the relative influence of genetic and extrinsic factors in its inheritance.

**Satin, a new hair mutation of the rabbit**, W. E. CASTLE and L. W. LAW (*Jour. Heredity*, 27 (1936), No. 6, pp. 235-240, figs. 3).—After presenting a chromosome map of the rabbit showing the location of 15 genes on 10 of the 22 chromosomes, a mutation, designated as satin, is described. The coat is smoother and glossier than normal, and the hairs are more slender and have a thinner cuticulum. A detailed description is given of the hair structure. The satin mutation is due to a single gene recessive to the normal. It appears to be independent of the genes for albinism and brown, angora and English, extension, furless, rex, rex, agouti, and the blood group gene H<sub>i</sub>.

**A tame-wild rabbit cross**, W. K. WILSON (*Jour. Heredity*, 27 (1936), No. 3, pp. 127-131).—In an attempt to produce a homozygous strain of agouti rabbits

of a sturdy type with dense fur, two wild bucks were crossed with three Sitka (Black Beverin) does. Considerable difficulty was experienced in making the original cross, and the mortality was heavy and litter size small in the  $F_1$ ,  $F_2$ , and  $F_3$  generations. The contrasting characteristics of size and temperament in the parents were essentially intermediate in the progeny. The wild characteristic was evident in  $F_3$ s, and no truly docile animals appeared. A wide banding condition on the agouti hair resulting in a pale color was observed in the  $F_2$  population. This seemed to behave as a Mendelian recessive to normal agouti banding.

Some observations upon the mitotic and meiotic divisions in the Wistar rat, I, II, W. BRYDEN (*Cytologia*, 6 (1935), No. 2-3, pp. 300-307, figs. 8; 7 (1936), No. 3, pp. 389-395, figs. 6).—Two papers are presented.

I. *The effect of changes in temperature.*—The frequencies of chiasma and bivalent types observed on microscopic examination of testes removed from rats subjected to temperatures gradually dropped from 17° to 3° C. during a period of 4 hr., indicated that the mechanism of chromosome movement, chiasma formation, terminalization, etc., were affected by the treatment. However, no degeneration was noted, although the treatments were continued as long as 10 hr.

II. *Changes in temperature over localised areas.*—Temperature changes in the scrotum of rats were brought about by the application of ether and ethyl chloride or by heat, and after 8 hours' treatment the testicles were fixed and studied. Chiasma formation in the testicles subjected to higher, lower, or alternating temperatures and the controls did not show significant differences. Differences in the coefficients of terminalization and the frequency of the stages of meiosis are discussed.

The frillback pigeon, H. WEXELSLN (*Jour. Heredity*, 27 (1936), No. 4, pp. 161-163, figs. 3).—In a study of the inheritance of the frillback character in pigeons, in which the feathers on the shield are curled and twisted, it was found that the character was probably dependent upon two factors, with perhaps minor modifiers influencing the degree of curling. The  $F_1$  hybrids were intermediate although somewhat variable in the degree of twisting of the feathers. Backcross progeny to the frillbacks and the normal smooth pigeons were also variable. An intermediate form designated as ruffled also appeared.

[Studies of the physiology of reproduction in animals] ([New York] Cornell Sta. Rpt. 1936, pp. 89, 90, 133, 134).—Brief results are given as to the use of hormones in combating sterility in dairy cattle, by S. A. Asdell, S. E. Smith, and M. G. Fincher; the use of pituitrin for hastening birth and lowering the percentage of still-born pigs, by Asdell and J. P. Willman; selection for lowered mortality in White Leghorn fowls, by F. B. Hutt, G. O. Hall, and E. L. Brunett; studies of the influence of progynon B, parathormone, and the thyrotropic hormone and combinations of hormones on the blood calcium of pullets, and the glycine content of chondrodystrophy and normal fowl embryos, both by Hutt and A. R. Patton; and progress on studies of the inheritance and linkage relations of various characters in the fowl, by Hutt.

Participation of ovarian factors other than "estrin" in the estrus phenomenon, S. C. FREED, T. GARVIN, and S. SOSKIN (*Soc. Expt. Biol. and Med. Proc.*, 35 (1936), No. 3, pp. 409-414).—The daily administration of 25 international units of dihydroxyestrin benzoate to normal and castrated adult female rats for 4, 20, 30, and 60 days before sacrificing them showed, from careful examination, that the uteri of the castrated females showed a typical oestrous reaction whereas the normals were in various stages of dioestrus.

After 20 days the ovaries of the normal animals had undergone considerable hypertrophy, and after 30 and 60 days the uteri were hypertrophied. As three principal differences were noted in the response of normal and castrated animals to oestrin administration, it is considered that the ovaries elaborate a factor concerned in the inhibition of the uterine response, rhythmic activity of the endometrium, and augmentation of the uterine response to oestrin. Evidently oestrin alone cannot completely replace the ovary in inducing the uterine response.

**Experiments in the physiology of mammary development and lactation,** S. A. ASDELL, H. J. BROOKS, G. W. SALISBURY, and H. R. SEIDENSTEIN ([*New York*] *Cornell Sta. Mem.* 198 (1936), pp. 32, figs. 5).—Results are reported of the effects of the administration of acid and alkaline extracts of fresh and dried sheep pituitaries and the presence of corpora lutea on mammary gland growth and milk secretion in normal and ovariectomized rabbits. Evidently the growth and secretion effects were due to different hormones. Alkaline extracts of the anterior pituitaries caused growth in the mammary gland and milk secretion. Acid extracts had no effect on mammary growth but caused lactation in the dry developed gland within four days. Mammary gland development was associated with the presence of corpora lutea in the ovary, and could be produced by sterile matings, injections of anterior pituitary extract, or human pregnancy urine. As the mammary gland and uterine development could be induced in ovariectomized and hypophysectomized rabbits injected with oestrin and progestin, it is considered that the ovarian hormones act directly and not through the hypophysis. Phyone, the gonad-stimulating hormones, and pituitrin were without effect on the mammary glands. Theelin injected during pseudopregnancy carried mammary gland development no further than usual.

Studies of milk secretion in a few goats showed that injections of prolactin caused milk secretion and when injected late in lactation caused increased milk yield. From the experiments with goats, it is concluded that the mammary development is under the influence of the ovary and that normal decline in lactation is due to the senility of the mammary gland, but that rapid decline is due to the production of insufficient prolactin by the animal and could be rectified experimentally with good results.

**Sex-modification in the chick embryo resulting from injections of male and female hormones,** B. H. WILLIER, T. F. GALLAGHER, and F. C. KOCH (*Natl. Acad. Sci. Proc.*, 21 (1935), No. 11, pp. 625–631, figs. 4).—The effect of the male and female sex hormones on the development of the gonads and other sex organs in the chick during incubation were studied. The hormones were administered in doses of 0.1 cc into the egg albumen after 24 hr. incubation.

Theelin and theelol in the zygotically determined males produced a smaller testis than normal with the flattened form of the left ovary. The gonad thus contained both ovarian and testicular tissues. In females small doses affected the oviducts slightly, whereas large doses caused them to become much swollen. Injections of bull testis hormone produced no observable effects upon the form, size, and histology of the gonads of either sex. Human male urine injections resulted in the formation of a variable amount of cortex on the left testis and the gonad assumed a flattened form. The right testis, or ovary, was unaffected. The asymmetrical differences in the response indicated that the sex hormones do not originate a morphological component but merely activate one already normally present. The degree of intersexuality produced in males appeared roughly proportional to the quantity of female hormone injected. Evidently the male and female hormones stimulate, respectively, Wolfian and Müllerian sex ducts and are, therefore, sex specific. The differences in the

response from bull testis hormone and human male urine extracts were not fully understood.

**Testicular hormones and Sebright plumage**, C. H. DANFORTH (*Soc. Expt. Biol. and Med. Proc.*, 32 (1935), No. 9, pp. 1474-1476).—In a study of hen feathering in the Sebright bantam, three 5½-month-old cockerels were selected. One testicle was removed from one and later part of the other testicle, and both testicles were removed from another. The partially castrated bird finally became cock-feathered, while the capon showed capon feathering. This suggested that the type of feathering of Sebrights is controlled by the amount of testicular tissue present. Grafting bits of Sebright testes on the breast of a Sebright capon caused the development of cock feathering but later injections of beef testes and rat gonadotropic hormone produced hen-feathered plumage. Evidently the extracts from the bull testes and the rat augmented the action of the hormones of the cock-feathered male.

**The concentration of gonad-stimulating hormone in blood serum and of oestrin in the urine throughout pregnancy in the mare**, H. H. COLE and F. J. SAUNDERS (*Endocrinology*, 19 (1935), No. 2, pp. 199-208, figs. 2).—Studies were made at the California Experiment Station of the gonad-stimulating hormone in the blood and the oestrin present in the urine of four pregnant mares. When the gonad-stimulating hormone was first recognized in the blood as 390 rat units per liter at about 45 days, the amount increased very rapidly to about 50,000 rat units at 55 to 57 days and remained high for a period of nearly 50 days, after which it dropped rapidly.

A method of assay of the gonad-stimulating hormone interpreted directly from the weights of the ovaries of eight rats which receive a single subcutaneous dose on the twenty-fifth day of age with autopsy 120 hrs. later is suggested. However, the dose of the hormone must be less than 16 rat units.

Oestrin appeared in the mare's urine at about the one hundredth day of pregnancy and increased to the two hundredth and two hundred seventy-fifth day. Subsequently the concentration gradually dropped until the end of the gestation period. After parturition, oestrin could no longer be detected in the urine.

**Two gonadotropic substances in mare serum**, F. J. SAUNDERS and H. H. COLE (*Soc. Expt. Biol. and Med. Proc.*, 32 (1935), No. 9, pp. 1476-1478).—Several experiments at the California Experiment Station showed that pregnant mare serum contains two gonadotropic substances. One was destroyed by incubation after treatment with  $H_2S$  and the other was salted out with  $Na_2SO_4$ . The first was a luteinizing hormone similar to that occurring in the pituitary, but the other, while giving some follicle-stimulating response, did not give a clear response.

**Quantitative studies on the response of the capon's comb to androsterone**, A. W. GREENWOOD, J. S. S. BLYTH, and R. K. CALLOW (*Biochem. Jour.*, 29 (1935), No. 6, pp. 1400-1413, figs. 6).—Study was made of the influence of different conditions on comb growth in capons in response to the administration of five daily doses of androsterone. The comb response, measured as length-plus-height increase, was directly proportioned to the logarithm of the dose between the limits of 0.5 and 8 mg. Age and method of administration (subcutaneously or intramuscularly) were not important factors in causing variable results.

**Growth and maintenance of the fowl's comb by administration of androsterone**, R. K. CALLOW and A. S. PARKES (*Biochem. Jour.*, 29 (1935), No. 6, pp. 1414-1423, pl. 1, figs. 6).—The administration of doses of 0.5 to 5 mg of androsterone per day to capons was found to induce comb growth above normal, and crowing and treading occurred. The normal comb condition

could be maintained by doses of 1 mg per day, but the hormone was not able to maintain the vas deferens as adequately. Comparative comb response showed capons to be more sensitive to androsterone than hens, and Leghorns were more sensitive than Plymouth Rocks.

**Effect of androsterone and of male hormone concentrates on the accessory reproductive organs of castrated rats, mice, and guinea-pigs, R. K. CALLOW and R. DEANESLY** (*Biochem. Jour.*, 29 (1935), No. 6, pp. 1424-1445, figs. 9).—In a study of the effectiveness of androsterone in maintaining normal size in prostate and seminal vesicles of rodents, it was found that 1 mg daily maintained the normal growth and structure in the prostate of 15 castrated rats, but 2 mg were required to maintain normal seminal vesicles. In mice, these doses were not so effective. Comparable results were obtained with guinea pigs. Androsterone alone or in a combination with oestrone was not as effective in restoring atrophied prostates and seminal vesicles in castrated animals as was the commercial urine concentrate of the male hormone. From these results, it is concluded that certain urine concentrates of the male hormone may contain a male hormone other than androsterone.

### FIELD CROPS

**[Agronomic research in California]** (*California Sta. [Bien.] Rpt. 1935-36*, pp. 15-20 27-34, 61-65, 104, 105).—Outstanding findings and developments and their application to agricultural problems in the State are described from the results of breeding work with barley, wheat, corn, beans, alfalfa, sourclover (*Melilotus indica*), and sugar beets; experiments with flax in the Imperial Valley; sugar beet experiments dealing with irrigation, seedbed preparation, ridge v. flat planting, rotations, fertilizers, and nutritional studies on peat soils; forage work, including range management, effects of burning the range, chemical characteristics of range plants, tests of oats and vetch mixtures for hay, and cowpeas for summer forage; and improvement of soils with soil-building or cover crops as vetch, cowpeas, hyacinth-bean, guar, sourclover, and fenugreek. Weed control research considered methods of studying chemical weed killers, effects of soil texture on arsenic toxicity, factors affecting toxicity of chlorates and borax, the merits of carbon disulfide, sulfuric acid, and other chemicals, and control of Klamath weed (*St. Johnswort*) with chemicals. Certain lines of research were in cooperation with the U. S. Department of Agriculture.

**[Field crops work in Hawaii]**, C. P. WILSIE, [E. K.] AKAMINE, L. D. WHITNEY, M. TAKAHASHI, F. A. I. BOWERS, J. C. RIPPERTON, and D. W. EDWARDS (*Hawaii Sta. Rpt. 1936*, pp. 8, 11, 18-25, 40-42, figs. 2).—Progress results are reported on briefly from breeding work and fertility and cytological studies with sweetpotatoes; variety trials with cassava, edible canna, potatoes, and soybeans for seed and forage; taro varietal and classification studies and a survey of taro-producing areas; seed storage experiments; fertilizer experiments with potatoes; adaptation studies with forage grasses and legumes; and cutting tests with alfalfa and Napier grass.

**[Field crops and plant breeding research in New York]**, J. K. WILSON, T. L. LYON, E. W. LELAND, J. A. BIZZELL, R. A. EMERSON, A. C. FRASER, B. MCCLINTOCK, H. H. LOVE, E. DORSEY, F. P. BUSSELL, W. T. CRAIG, R. G. WIGGANS, J. R. LIVERMORE, O. SMITH, and E. V. HARDENBURG ([*New York*] *Cornell Sta. Rpt. 1936*, pp. 74, 75, 76, 113-115, 141, 142, 144).—Brief progress reports (E. S. R., 74, p. 771) are given from breeding work with silage corn, wheat, oats, barley, potatoes, and soybeans; cytogenetic studies with corn; genetic studies with cereals; potato experiments, including fertilizer, soil reaction, cultural, and storage

studies; a rate of planting test with field beans; a comparison of several nitrogenous fertilizers for the production of timothy hay; and experiments concerned with the longevity and growth of alfalfa as affected by frequency of cutting, soluble carbohydrates of legumes in relation to silage production, and cross-inoculation of legumes. Certain projects were in cooperation with the U. S. Department of Agriculture.

[**Field crops work in West Virginia, 1935-36**] (*West Virginia Sta. Bul.* 278 (1936), pp. 13, 17-22, fig. 1).—Progress reports are made on agronomic experiments (E. S. R., 72, p. 606) carried on at the station and substations during the biennium ended June 30, 1936, in some cases in cooperation with the U. S. Department of Agriculture, and including breeding work with winter wheat and corn, and sweetclover for tolerance to acid soil and low coumarin content; studies of inheritance of resistance to root rot in tobacco and to wilt in water-melons; cultural experiments with potatoes and barley; fertilizer and liming tests with potatoes and a number of other field crops; reduction of erosion by including cover crops in the rotations (E. S. R., 76, p. 179); and pasture investigations, comprising a survey of the State's pastures, fertilizer and liming tests, relation of soil properties to botanical composition, and a grazing experiment.

**Proceedings of the Pasture and Hayland Conference, held at New York, N. Y., September 24, 1936** ([*Washington, D. C.*]: *Natl. Fert. Assoc.*, 1936, pp. 95).—The conference held September 24, 1936, under the auspices of the American Agricultural Editors' Association and the National Fertilizer Association emphasized not only proper management and fertilization of pastures and hayland, but also the relation of grass farming to the economical production of meat and milk, as well as to the broader program of soil conservation. The following papers by workers of State experiment stations, extension services, and other agencies are included in the proceedings: Purpose of the Conference, by C. J. Brand (pp. 7-10); Roughage in an Efficient Dairy Program, by A. J. Glover (pp. 11-16); Pasture Fertilization—The Changing Viewpoint of Twenty Years, by S. B. Haskell (pp. 17-23); Hay and Pasture Problems in the Northeastern States, by J. B. Abbott (pp. 24-37); Grass Silage and Its Possibilities, by C. B. Bender (pp. 38-40) (N. J.); Servicing the Farmer, by C. L. White (pp. 41-47); Grass Farming in the South—For Profit and Soil Conservation, by H. P. Cooper (pp. 48-53) (S. C.); Further Comments on Grass Farming in the South, by R. H. Lush (pp. 54-59) (La.); Fertilizing the Hay Crops, by T. E. Odland (pp. 60-69) (R. I.); Management and Fertilization of Permanent Pastures, by R. W. Donaldson (pp. 70-84) (Mass.); Supplemental Pastures, by H. R. Cox (pp. 85-89) (N. J.); and High Spot Summary, by H. R. Smalley (pp. 90, 91).

**Pasture improvement and management**, W. L. BURLISON, H. P. RUSK, and J. J. PIEPER (*Illinois Sta. Circ.* 465 (1936), pp. 50, pl. 1, figs. 20).—Practical information is given on the establishment and management of pastures, and suitable mixtures of grasses and legumes are recommended for different purposes and situations in Illinois. Eleven grasses and seven legumes adapted to Illinois conditions are described and their uses indicated.

"Success in establishing and maintaining good pastures depends on judicious choice of plants, use of high-quality seed, adequate testing and fertilizing of the soil, a compact seedbed, care in planting, and good judgment in grazing practices."

**Manual of the grasses of the West Indies**, A. S. HITCHCOCK (*U. S. Dept. Agr., Misc. Pub.* 243 (1936), pp. 439, figs. 374).—Descriptions, usually with illustrations and indicated distributions, are given for grasses known to grow in the West Indies. The economic grasses are discussed briefly. The sub-

families of Gramineae (Poaceae), the tribes, genera, and species are described with appropriate keys, and an index is included. This manual greatly extends and revises information presented earlier (E. S. R., 39, p. 440).

**The mechanism of pollination in alfalfa (*Medicago sativa*),** R. A. BRINK and D. C. COOPER (*Amer. Jour. Bot.*, 23 (1936), No. 10, pp. 678-683, figs. 2).—Pollination in alfalfa was studied at the Wisconsin Experiment Station. Under greenhouse conditions in the winter, tripping appeared to be practically indispensable to seed setting, but in the field many pods might arise from untripped flowers. The extent to which the stigmatic film acts as a block to pollination in the untripped flower is variable; its behavior probably accounts for much of the irregularity in seed formation in the field. In view of the greater reproductive capacity of hybrid v. inbred plants, the occurrence of a considerable amount of self-fertilization seemed consistent with the maintenance of much heterozygosity in alfalfa populations. Occasionally the amount of aborted pollen may be large enough to limit seed formation, although pollen abortion is not generally an important factor. Rarely pollination in the untripped flower may be prevented by an abnormal positional relationship between the stigma and anthers.

**The effect of late summer and early fall cutting on crown bud formation and winterhardiness of alfalfa,** V. W. SILKETT, C. R. MEGEE, and H. C. RATHER (*Jour. Amer. Soc. Agron.*, 29 (1937), No. 1, pp. 53-62).—A study of the effect of late summer and early fall cutting on the alfalfa plant was made by the Michigan Experiment Station on plats cut September 1, 15, and 30 and October 15 and 30, 1934, and from a similar set of plats in 1935.

Compared to plants not cut or cut during October, alfalfa cut in September developed fewer crown buds per plant, produced fewer stems when active growth was resumed in the spring, produced a significantly less yield of first crop of forage the next year, had roots lower in percentage of dry matter and higher in percentage moisture, and were more susceptible to winter injury as indicated by electrical conductivity determinations and severe winter killing and heaving of plants. While no consistent differences in factors studied occurred in the second crop, the total hay yield for the season from plants cut on critical September dates was significantly less than that of plants not cut on these dates. The quantity of carbon dioxide liberated from the roots of alfalfa plants which were cut and those not cut did not differ significantly. Seasonal weather conditions influenced the exact date of cutting upon which maximum injury to the plant resulted. Plants from which first and second cuttings had been removed at normal dates were cut during late October with little effect from this removal of top growth.

The lower percentages of dry matter in the roots indicated that cutting in September induced the roots to draw upon the reserves of the root to initiate new growth.

**Illinois corn performance tests.—Results for 1935 and 1936,** G. H. DUNGAN, J. R. HOLBERT, W. J. MUMM, J. H. BIGGER, and A. L. LANG (*Illinois Sta. Buls.* 427 (1936), pp. 281-340, figs. 2; 429 (1937), pp. 389-420, fig. 1).—Corn performance tests (E. S. R., 73, p. 35), continued in 1935 on experimental fields in 7 different geographical sections of Illinois, included 46 open-pollinated varieties, 26 composite samples of open-pollinated corn, and 202 hybrids. The detailed performance of entries on each field is set forth in tables.

In all sections the hybrids demonstrated their superiority over the best open-pollinated varieties. In central and north-central Illinois the 5 best hybrids outyielded the 5 best open-pollinated varieties by 18.2 and 20.3 bu., respectively, of sound corn an acre, and in the southeastern section by 6 bu. Some of the better hybrids and open-pollinated varieties included in the regular performance

tests in 1935 were tried out also on soils of different corn-producing capacities. The greatest differences occurred on land of high productivity. In the three silage tests hybrid entries did not greatly exceed open-pollinated entries in total yield of silage, but did surpass them in the grain fraction, i. e., in feeding value. The good hybrids were also superior to open-pollinated varieties in standing ability. Yields from second-generation hybrid seed did not exceed those from adapted open-pollinated varieties and were much below yields of first-generation hybrids.

In 1936, the 234 kinds of corn tested in 21 fields included 38 open-pollinated varieties and 196 hybrids.

The best hybrids again were found superior to the best open-pollinated varieties in all sections. The 5 best hybrids in northern, north-central, central, and south-central Illinois exceeded in yield the 5 best open-pollinated varieties by 15.7 bu. of sound corn per acre, or over 46 percent. The best hybrid entries in the two silage tests surpassed open-pollinated entries in total yield of silage as well as in grain fraction, or feeding value. Some of the better hybrids, with Station Yellow Dent as a check, grown on soils varying in productivity, were again found to be favored by a good soil to a greater extent than were open-pollinated varieties.

The relation of moisture content and time of harvest to germination of immature corn, G. F. SPRAGUE (*Jour. Amer. Soc. Agron.*, 28 (1936), No. 6, pp. 472-478, figs. 2).—Germination and moisture studies were made by the U. S. D. A. Bureau of Plant Industry, cooperating with the Missouri Experiment Station, on field-grown corn all pollinated on a single day and with 3 to 5 ears harvested at 5-day intervals starting 10 days after pollination and continuing until immediate normal germination was obtained. The moisture content necessary for germination also was determined.

Afterripening of immature corn was concurrent with the loss of moisture. Immature corn planted just after harvest was observed to exhibit great variability in time of germination. With a decrease in moisture content, the percentage of seeds germinating rose and the variability in time required for complete germination decreased. It appears that the moisture content of immature seeds must be reduced to approximately 25 percent before normal germination occurs. That corn kernels require a minimum of approximately 35 and 60 percent of moisture in whole grain and embryo, respectively, before germination can occur was indicated by data from two experiments. It is suggested that the mechanism which inhibits the normal germination of newly harvested immature corn operates in the scutellum rather than in the endosperm or pericarp.

Protein content of corn as influenced by laboratory analyses and field replication, W. H. LEONARD and A. CLARK (*Colorado Sta. Tech. Bul.* 19 (1936), pp. 9).—Determinations made on composite shelled samples from each replicate in the rate of planting test noted earlier (E. S. R., 73, p. 606) showed shelled grain from Golden Glow to contain more protein than that from Pride of the North. The protein content of shelled corn varied markedly from year to year, and was affected significantly by the planting rate, the thinner rates resulting in the highest protein percentage. The method of planting (hills or rows) had no effect on the amount of protein.

Plat replication gave the larger error when the standard errors due to plat replicates and due to duplicate samples for protein analysis were compared, the ratio between the two being 6.1:1. Drawing two samples for protein instead of one did not perceptibly increase the precision of the experiment. Computation of the cost ratio of plat replicate to sample repli-

cate indicated that the analysis of a duplicate sample from each plat would have been justified in producing the most economical design only if the cost per plat had been 151 times the cost per analysis.

**Variability of fiber length in a relatively uniform strain of cotton, T. R. RICHMOND and H. J. FULTON** (*Jour. Agr. Res. [U. S.]*, 53 (1936), No. 10, pp. 749-763, figs. 4).—Fiber-sorting methods, developed through use of the McNamara-Stutts fiber sorter (E. S. R., 74, p. 190) on samples of Pima cotton (*Gossypium barbadense*) grown at Sacaton, Ariz., materially reduced the time required for making fiber arrays of cotton of the Egyptian type. The mean length was found to be highly correlated with the upper quartile length and the combing length. Differences in mean lengths from sample to sample on the plant and from plant to plant in the row were not significant. The variance on the individual seeds amounted to over 95 percent of the total variance in fiber length, the remainder being attributable to that occurring among the means of samples on the plant and of plants in the row.

**Experimental culture of potatoes in mountain and plain, Morocco, 1935** [trans. title], É. MÎÈGE (*Compt. Rend. Acad. Sci. [Paris]*, 202 (1936), No. 25, pp. 2098-2101).—The yields and vitality were much higher in the mountains than in the plains whatever the origin and method of storage of the seed.

**Reclamation of potato land flooded by salt water, G. V. C. HOUGHLAND** (*Amer. Potato Jour.*, 14 (1937), No. 1, pp. 19-22, fig. 1).—Studies of the soils and potato crops on areas flooded by salt water, made by the U. S. Department of Agriculture in cooperation with the Virginia Truck Experiment Station and on Long Island, N. Y., led to the conclusion that potatoes may be grown successfully on land flooded with salt water if the salt content is below 1,000 p. p. m. (0.1 percent) at time of planting and normal rainfall occurs throughout the season. Suggested reclamation methods are mentioned.

**Some changes in potato fertilizer use, B. E. BROWN** (*Amer. Potato Jour.*, 13 (1936), No. 12, pp. 327-339).—Some of the more important changes which have taken place in the use of potato fertilizers since the beginning of the present century discussed in this paper include changes in fertilizer materials, fertilizer composition, plant food concentration of fertilizers, acid and neutral fertilizers, uncommon plant food deficiencies, and fertilizer placement.

**Results from the lime experiment with potatoes for 1936, J. B. HESTER** (*Amer. Potato Jour.*, 13 (1936), No. 12, pp. 339-342).—In further tests (E. S. R., 74, p. 191) at the Virginia Truck Experiment Station the finely processed limes produced the greatest returns; hydrated and limestone dolomite, hydrated calcium, and oyster shell produced yield increases exceeding 56 percent; frequent light applications surpassed heavier ones made less often; and over a 5-yr. period dolomitic and calcium limes gave respective increases of 33 and 24 percent over the check.

**The potato in Canada, T. F. RITCHIE** (*Canada Dept. Agr. Pub.* 483 (1936), pp. 57, figs. 29).—Practical recommendations on potato varieties, seed preparation, cultural and field methods, and harvesting and storage practices are supplemented by information on the status of the crop in Canada; production costs; insects and their control, by A. G. Dustan; and potato diseases and control.

**Rice and rice planting in the South Carolina low country, D. DOAR** (*Contrib. Charleston Mus.*, 8 (1936), pp. 70, pls. 6, figs. 5).—This history of rice production in South Carolina is related in chapters entitled Rice and Rice Planting in the South Carolina Low Country, by D. Doar (pp. 7-42); The Last Days of Rice Planting, by T. D. Ravenel (pp. 43-50); and The True Story of How the Madagascar Gold Seed Rice Was Introduced Into South Carolina

(pp. 51-53) and Bibliography of the Rice Industry in South Carolina (pp. 54-68), both by A. S. Salley.

**The cultivated races of sorghum**, J. D. SNOWDEN (*London: Adlard & Son, 1936, pp. VII+274, pls. 4, figs. [32]*).—This volume considers the botanical history of the cultivated sorghums, including nomenclature and early classification; describes characters significant in classification; and provides determinative keys to the subseries, species, and varieties. The classification adopted follows and extends that of O. Stapf. Each species is discussed with citations, synonymy, history, botanical description, varietal characteristics, distribution, and cultural and economic notes. The relationships of wild and cultivated sorghums are explained and shown diagrammatically. A classified bibliography arranged chronologically, and indexes of botanical and vernacular names and countries and regions are appended.

**Growing and feeding grain sorghums**, J. H. MARTIN, J. S. COLE, and A. T. SEMPLE (*U. S. Dept. Agr., Farmers' Bul. 1764 (1936), pp. II+46, figs. 33*).—Cultural and field practices and irrigation, harvesting, and threshing methods involved in growing grain sorghums are outlined; important varieties and their characteristics are described; and information is given on the importance of grain sorghums, their adaptation, uses, place in the cropping system, the requirements for and returns from growing grain sorghums, and diseases and insect pests. The sections on feeding treat of feeding value, grain sorghum silage, grinding the grain and fodder, and pasturing grain sorghums, and suggest a number of rations containing grain sorghums.

**Effect of germination and seed size on sorghum stands**, A. F. SWANSON and R. HUNTER (*Jour. Amer. Soc. Agron., 28 (1936), No. 12, pp. 997-1004, figs. 2*).—The discrepancy between laboratory and field germination of the better-known sorghums and the influence of kernel size on the number of plants per acre were studied cooperatively by the Kansas Experiment Station and the U. S. Department of Agriculture.

At Hays, 1932-34, the laboratory germination of 17 varieties ranged from 89 to 98 percent, averaging 95, whereas field germination was 45, 45, and 61 percent for May 15, June 1, and June 15 plantings, averaging 50 for all dates. Germination increased considerably in June 15 plantings, due to more favorable soil temperatures. Germination was highest as a rule for sorgos and darso and lowest for certain soft-seeded grain sorghums, including feterita, Club, and hegari. Better stands usually have been obtained with the harder seeded varieties having a thin mesocarp (E. S. R., 60, p. 628) than with feterita. Since the number of kernels per pound of sorghum seed varies approximately from 12,000 to 35,000, depending on the variety and plumpness of the seed, size planting adjustments must be made to secure proper stands.

Seed of 7 varieties, taken from standing stalks in the cold and rainy fall of 1933 when seed of most sorghums were slow in maturing and drying, made low field germinations even when harvested before low temperatures approached, and only about one-half as much as when collected after freezing temperatures occurred. In 1931 with 6 varieties, high germination was obtained from soft dough seed as compared with fully ripe seed, but delayed harvest and exposure to frost and sleet greatly reduced germination. No stimulation of vegetative vigor was noted in seedlings or plants from seed treated with Coppercarb and mercurial compounds in 1927 and 1928. Feterita responded better to seed treatment in increased germination than did Red Amber sorgo and Dawn kafir.

**Effect of thiourea upon proximal dominance in the sweet potato**, F. HORSFALL, JR. (*Amer. Soc. Hort. Sci. Proc., 32 (1935), pp. 471, 472*).—Porto Rico

sweetpotato roots were soaked in distilled water solutions of 2 to 4 percent thiourea for from 1 to 2 hr. at the University of Missouri. When immersion was longer than 1 hr., a retarding effect was evident which was also true of the 4 percent solution for 1 and 2 hr. However, roots treated with 4 percent for 1 hr. later produced a good crop of sprouts well distributed over the surface. All treated roots showed a loss of proximal dominance in a second crop of slips similar to that earlier.

**The influence of handling seed stock on the shrinkage, plant production, and yield of the Triumph sweet potato,** W. S. ANDERSON and J. B. EDMOND (*Amer. Soc. Hort. Sci. Proc.*, 32 (1935), pp. 466-470).—Sweetpotatoes, in experiments at Laurel, Miss., were dug December 5, 1934, cured in crates December 8-24, stored from December 24 to March 15, 1935, bedded March 30, and plants pulled and transplanted to field plats from April 29 to August 2, and the crop harvested October 9. Roots "carefully handled", i. e., placed directly from the row into crates lined with cotton outing cloth, lost less weight in storage, had smaller percentage of storage rots, and were more efficient plant producers than roots "commercially handled", i. e., thrown into unlined crates. The handling of the seed stock apparently had slight influence on the yielding ability of the transplant.

**Curing and storing sweet potatoes without artificial heat,** W. D. KIMBROUGH (*Amer. Soc. Hort. Sci. Proc.*, 32 (1935), pp. 456-459).—Keeping of sweetpotatoes in storage, according to results at the Louisiana Experiment Station, has differed little as to amount of shrinkage or rot whether or not artificial heat has been provided. In the Sunset district large quantities of sweetpotatoes have been stored in buildings similar to warehouses, and the roots themselves seem to provide enough warmth during cold spells to obviate artificial heating during storage. Most of the crop is dug in October, which is comparatively warm and usually dry.

**Varietal studies of flue-cured, burley, and dark tobaccos,** N. A. MACRAE and R. J. HASLAM (*Canada Dept. Agr. Bul.* 178 n. ser. (1935), pp. 61, figs. 7).—Tobacco varieties collected from tobacco districts in Canada and the United States are described as to field growth measurements, growing plant and green leaf, relative maturity, yields, sorting and grading, and price and grade index. The 59 varieties and strains of flue-cured are classified into 9 groups; the 36 sorts of Burley into 7 groups; and the 31 kinds of dark tobacco into 5 groups.

**Harrow Velvet**, a new variety derived from a strain of White Burley resulting from a cross made by W. D. Valteau of the Kentucky Experiment Station, is described as early and consistently resistant to black root rot and having other good characteristics.

**Rate of water loss in wheat varieties and resistance to artificial drouth,** B. B. BAYLES, J. W. TAYLOR, and A. T. BARTEL (*Jour. Amer. Soc. Agron.*, 29 (1937), No. 1, pp. 40-52, figs. 3).—Eight varieties of spring wheat with about the same relative time of maturity were grown in greenhouses at the Arlington, Va., Experiment Farm. Two plants each of two varieties were grown in an 8-in. pot, each variety being paired with each other variety to compensate for soil moisture variations.

When some pots were placed on a revolving table in a current of hot air, from 92° to 98° F., differences in amount of injury between such varieties as Baart and Hope were demonstrated clearly, but smaller differences between other wheats were not so evident. In order of increasing injury the ranking was Onas, Baart, Kubanka, Huston, Ceres, Marquis, Hope-Ceres, and Hope. The rates of water loss from cut plants dried at room temperatures were determined by weighing at intervals. When grown with normal soil moisture

the ranking with respect to decreasing rates of water loss was Kubanka, Baart, Onas, Ceres, Marquis, Huston, Hope, and Hope-Ceres. When the plants were subjected to low soil moisture, considerable variability was found between pots. Evaluation of the varieties from both tests was consistent with field performance under drought conditions.

Based on average results for 1934 and 1935, secured in the field at Tucson in cooperation with the Arizona Experiment Station, varietal ranking as to decreasing resistance to water loss was Kubanka, Baart, Ceres, Onas, Marquis, Huston, Hope-Ceres, and Hope, an order corresponding closely with that established by greenhouse-grown material. Results from the same wheats grown at Pullman, Wash., and Moro, Oreg., did not conform so closely to this order.

**Proceedings of the Association of Official Seed Analysts of North America, 1936** (*Assoc. Off. Seed Anal. North Amer. Proc.*, 28 (1936), pp. 115, figs. 11).—The activities of the association during the year ended June 1936 are reported with an account of the twenty-eighth annual meeting at Rochester and Geneva, N. Y., June 16-19, 1936. The following papers by State experiment station and U. S. Department of Agriculture workers and those from other agencies are included: History of Association of Official Seed Analysts, by A. M. Lute (pp. 27-30) (Colo.); The Other Fellow's Viewpoint (pp. 32-36) and Weight Per Bushel of Wheat in Relation to Its Seed Value (pp. 50-61), both by W. O. Whitcomb, and Further Studies With the Germination of Crested Wheat Grass, by W. D. Hay (pp. 86-88) (all Mont.); Should Our Association Be Interested in the Two Purity Analysis Methods of the International Seed Testing Rules? (pp. 42, 43), Toxic Effect of Certain Seed Treatments as Revealed in Germination Response (p. 92), and The Better Seed Program of New York State (pp. 112-114), all by M. T. Munn, A Preliminary Report on the Germination of Mustard Seed (pp. 74-76) and The Germination of Lettuce Seed in the Laboratory and in the Field (pp. 80-83), both by A. L. Shuck, Procedure Used in an Analytical and Mycological Study of Seed Wheat (pp. 89-91) and Prevalence and Significance of Fungous Associates of Pea Seeds (pp. 101-107), both by W. F. Crosier, and Some Observations on the Decline in Viability of Cheving's Fescue Seed (*Festuca rubra commutata*), by S. R. Patrick (pp. 76-79) (all N. Y. State); "Non-Warranty" or Disclaimer Clause, by M. H. Snyder (pp. 44-46) (W. Va.); Seed Inspection in Canada, by W. J. W. Lennox (pp. 46-52) (Ont.); Seed Inspection in New York State, by J. C. Stephens (pp. 53, 54) (N. Y.); The Interstate Clause of the Federal Seed Act to Date, by W. A. Davidson (pp. 54-57), and Growing Tests in an Attempt to Differentiate *Melilotus alba* and *Melilotus officinalis* on Seed Characteristics, by F. M. Torpy and E. F. Sirrine (p. 58) (both U. S. D. A.); Comparative Absorption of Water by Endosperm and Embryo of Corn Kernels, by G. N. Davis and R. H. Porter (pp. 62-67), Germination of Injured Weed and Crop Seeds, by R. H. Porter and K. Koos (pp. 68-73), Special Equipment for Germinating Corn and Soy Beans, by R. H. Porter, G. N. Davis, and E. L. Erickson (pp. 83-86), and Relation of Seed Disinfectants to Seed Analysis, by R. H. Porter (pp. 93-101) (all Iowa); and Pathogenic Associates of Tomato Seed: Their Prevalence, Relation to Field Disease, and Elimination, by J. H. Miller (Univ. of Ga.) and W. F. Crosier (N. Y. State) (pp. 108-111).

**Eradication of bindweed in bluegrass lawns**, R. C. KINCH and F. D. KEM (*Jour. Amer. Soc. Agron.*, 29 (1937), No. 1, pp. 30-39).—Complete eradication of bindweed in a lawn at the Nebraska Experiment Station by pulling the plants at weekly intervals required one season and a half and a total of 29 treatments, and with pulling at 2-week intervals required two entire seasons and a total of 20 treatments. Pulling at 3- and 4-week intervals for 2 yr.

failed to eradicate the weed. Cost of eradication by pulling averaged from \$1.25 to \$1.50 per square rod.

Light sprayings on individual bindweed plants with sodium chlorate solutions of 0.5, 1, and 2 lb. per gallon at 2-week intervals gave complete eradication with very little difference in the effects of the three concentrations. Grass areas from 2 to 4 in. in diameter were killed by repeated sprayings of one place where bindweed plants kept coming up. Individual treatment of bindweed plants with 5 g of sodium chlorate gave complete eradication in one season, and when the lawn was watered thoroughly after application the bluegrass was injured very little. Broadcasting sodium chlorate and immediately leaching it in the soil by applying water killed bindweed in a year and left the bluegrass relatively uninjured. A total of 5 lb. of sodium chlorate in 1-lb. applications at 2-week intervals gave best results. The toxic action of sodium chlorate on bluegrass was controlled by watering.

**Field bindweed and control methods for South Dakota,** C. J. FRANZKE and A. N. HUME (*South Dakota Sta. Bul.* 305 (1936), pp. 51, figs. 25).—Experiments in the eradication of field bindweed (*Convolvulus arvensis*) by fallowing, paper mulch, application of chlorates and other chemicals, and by the use of smother crops, carried on at the station and substations, are reviewed in detail, and characteristics of the weed and its effects on crop production are described. The control method promising to be most effective, according to results obtained, provides for the introduction into the crop rotation of summer fallow followed by a smother crop of winter rye, with repetition for at least two consecutive seasons and probably three in most cases. Thirty-one references are appended.

**Rootsprouts as a means of vegetative reproduction in *Opuntia polyacantha*,** A. D. HARVEY (*Jour. Amer. Soc. Agron.*, 28 (1936), No. 9, pp. 767, 768, figs. 3).—The heavy invasion of *O. polyacantha* on range pastures of eastern Colorado, where it often composes as much as 40 percent of the vegetative cover, is accelerated greatly by the root sprout method of reproduction. The two definite types of roots disclosed were a comparatively small lateral root, rather succulent and with numerous ramifications, and a larger main lateral, woody in nature and not so extensively ramified. The main laterals which separate from the parent plant run to varied lengths close to the soil surface of the ground. From the main laterals and its subdivisions young plants are borne which show the initial development from minute areolae with a compact cluster of fine glochines.

## HORTICULTURE

**The relation of growth-substances, or hormones, to horticultural practice: A review,** M. A. H. TINCKER (*Jour. Roy. Hort. Soc.*, 61 (1936), No. 9, pp. 380-388, pls. 5).—This is a concise, clear statement of the background and present status of the subject.

**Some relationships of cultural systems to soil organic matter,** L. HAVIS and J. H. GOURLEY (*Amer. Soc. Hort. Sci. Proc.*, 32 (1935), pp. 99-102, fig. 1).—Determinations by the Ohio Experiment Station of the organic matter in soils of plats at Marietta, where cultural and fertilizer experiments have been in progress for several years, showed some accumulation of humus. On the plat which over a period of 21 yr. received a total of 328 tons of manure per acre plus cover crops and crop residues, the soil contained 2.73 percent of organic matter as compared with 2.11 percent for the control. It is pointed out that the control plat probably had lost some of its original organic

material. The authors state that the results fail to show that large applications of organic matter necessarily mean large increments of humus.

**A subirrigation method of supplying nutrient solutions to plants growing under commercial and experimental conditions**, R. B. WITHEROW and J. P. BIEBEL (*Jour. Agr. Res. [U. S.]*, 53 (1936), No. 9, pp. 693-701, figs. 3).—From the Indiana Experiment Station, "a subirrigation method of supplying nutrient solutions to plants growing in sand culture which lends itself to large-scale production is described. It consists in principle of pumping nutrients from a submerged reservoir into the bottom of a shallow bed of fine gravel or cinders with a centrifugal pump. The pump is controlled by an electric time switch which stops the operation when the bench is flooded. The solution then flows back into the tank through the pump by gravity.

"Modifications of the method are discussed for use in experimental set-ups on a small scale. . . .

"The advantages of the system are (1) frequent and complete flushing of the roots with air and nutrient solution, (2) economy of nutrients, since the solution drains back into the tank again, and (3) completely automatic operation over long periods of time."

**Leaf injection**, W. A. ROACH (*East Malling [Kent] Res. Sta. Ann. Rpt.*, 23 (1935), pp. 134-136, figs. 2).—The cut tips of chlorotic leaves on a small pot-grown pear tree were immersed in 0.1 percent solutions of zinc sulfate, manganese sulfate, iron tartrate, and copper sulfate. After 18 hr., the veins of the copper-treated leaf had turned brown with brown spots on the leaf. When the copper sulfate was reduced to 0.05 percent, the injury after 24 hr. was confined to a browning of the cut edges. None of the chemicals, except copper sulfate, had any harmful effect after five days' injection, but iron tartrate was the only beneficial substance for restoring the normal green color. The entire tree was restored to a normal green by injecting iron tartrate into the trunk.

**Tree injection, 1935 experiments.—A progress report**, J. HEARMAN, B. F. GOODMAN LEVY, and W. A. ROACH (*East Malling [Kent] Res. Sta. Ann. Rpt.*, 23 (1935), pp. 137-141, figs. 4).—The earlier conclusion, namely, that leaf damage from too strong concentrations of injected chemical nutrients will become apparent within a few hours and always within a day after injection is completed, was not sustained in 1935 when a severe spring freeze occurred about the middle of May. Damage was not evident until three days after injection and was idfferent in symptoms from that of 1934. Apparently due to the freeze, the leaves continued in an immature condition after unfolding.

**Evidence as to how freezing kills plant tissue** W. H. CHANDLER and A. C. HILDRETH (*Amer. Soc. Hort. Sci. Proc.*, 32 (1935), pp. 27-35, fig. 1).—Using as material the pollen of four plants, Lukens Honey peach, Himalaya blackberry, a variety of amaryllis, and the yellow snapdragon, the authors found that pollen frozen as it comes from the anthers kept better at  $-15^{\circ}$  to  $-17^{\circ}$  C. than at room temperature. Pollen covered with freezing water and held at  $-15^{\circ}$  to  $-17^{\circ}$  was nearly all killed in 20 min. Fresh pollen coated with castor oil or with Wesson oil was uninjured by the ice when held in distilled water at  $-15^{\circ}$  to  $-17^{\circ}$ . Pollen held at the same temperatures in strong solutions of sucrose or of dextrose was not injured until the water and sugar were crystallized rather firmly. At the same temperatures, pollen placed in concentrated peach bark sap suffered much less injury than comparable pollen in ice of distilled water. At room temperatures, the sap killed practically all the pollen in a short time. From the results and from a general study of the entire problem, the authors are inclined to accept the Maximow theory that

killing of protoplasm at low temperatures is due to direct effects of the ice masses rather than a concentration or the changing of the sap caused by freezing out of the water.

[**Horticultural investigations by the California Station**] (*California Sta. [Bten.] Rpt. 1935-36, pp. 20-23, 34-53, 102-104, 105-108, 126, 127*).—General comments are presented on the results of studies on citrus fertilization; the relation between soil nutrients and citrus composition; fertilization of the Persian walnut; composition of date fruits; development of disease-resistant vegetables including cantaloups, watermelons, and tomatoes; breeding of marketable size watermelons; development of thrips-resistant onions; improvement of the carrot; structure of celery fibers or strings; breeding of new walnut and citrus varieties; rootstock effects in citrus; rootstocks for deciduous fruit trees; nematode-resistant rootstocks; oak-root-fungus-resistant stocks; pollination of cherries and pears; breeding of new fruits; blight-resistant stocks of pears; grape rootstocks resistant to phylloxera and nematodes; inheritance of color, disease resistance, and flower type in garden flowers; irrigation requirements of deciduous fruit trees, grapes, tomatoes, oranges, and lemons; fertilization of deciduous fruits; nature of bleeding in the grapevine; and on the precooling of pears and asparagus prior to long distance shipments.

[**Horticultural investigations by the Hawaii Station**], J. H. BEAUMONT, C. P. WILSIE, M. TAKAHASHI, [W. W.] JONES, W. B. STOREY, R. H. MOLTZAU, [J. E.] WELCH, J. C. THOMPSON, J. C. RIPPEYTON, D. W. EDWARDS, [E. T.] WATANABE, and R. K. PAHAU (*Hawaii Sta. Rpt. 1936, pp. 8-10, 24, 25-33, 42, 44-50, 93-95, figs. 4*).—There is presented in this annual report of progress information on the following studies: Breeding of lettuce; testing of tomato and sweet corn varieties; introduction of litchi, macadamia nuts, and other plants; selection of improved strains of papaya; fixation of flower type in the papaya; selective breeding and propagation of litchi and lungan; chromosome numbers in species of *Passiflora*, *Eugenia*, and other plants; variety testing and propagation of the avocado, mango, and other tropical species; introduction of new forms of citrus; improvement of the macadamia nut by selection and top-working; propagation of the macadamia nut; variety tests of truck crops; nitrogen requirements of the tomato; fertilizer requirements of vegetables and coffee; control of dieback of coffee by pruning and fertilization; effect of fertilizers on the chemical composition of coffee berries; and the grading, curing, and cracking of macadamia nuts.

[**Horticultural investigations by the West Virginia Station**] (*West Virginia Sta. Bul. 278 (1936), pp. 5, 6, 10-13*).—Among studies discussed are those dealing with the chemical nature of the pigment forming the red color in the skins of Winesap apples; the effect of ethylene, ethylene chlorohydrin, and ultraviolet irradiation on stored apples; value of nitrogen gas as a preservative for black walnut kernels; comparative number of pollen grains produced by different apple varieties; effect of sudden temperature drops on the viability of peach flower buds; nature of winter injury to apple fruit buds; the testing of apple and cherry rootstocks; depth of penetration of apple roots; methods of training young apple trees; variety testing of fruits; the nature of cracking in Stayman Winesap apples; and rotations for vegetables.

[**Olericultural investigations by the Cornell Station**] ([*New York*] *Cornell Sta. Rpt. 1936, pp. 115, 139-141, 142-144, 145*).—Included are brief reports on the progress of the following studies: Cabbage breeding by C. H. Myers; fertilizer requirements of vegetable crops grown on Long Island, by P. H. Wessels and J. D. Hartman; fertilizers and manures for asparagus, by Wessels and H. C. Thompson; soil reaction for vegetable crops, by Wessels, H. S. Cunnings-

ham, and Hartman; the handling and storage of vegetables, by H. Platenius, J. E. Knott, and Hartman; variety and strain tests of vegetables, by P. Work and E. V. Hardenburg; lettuce improvement, by Knott; and color development in tomatoes, by O. Smith.

**The culture of truck crops for exportation** [trans. title], L. A. SERRANO, C. ESTEVA, JR., and A. RIOLLANO (*Puerto Rico Col. Sta. Circ. 105 (1936), Span. ed., pp. 56, figs. 23*).—Prefacing the paper with statistical information on the present status of the industry, the authors present information on growing and preparation for shipment of cucumbers, peppers, and tomatoes.

**The influence of commercial fertilizers, potassium iodide, and soil acidity on the iodine content of certain vegetables**, W. B. MACK and E. P. BRASHER (*Jour. Agr. Res. [U. S.], 53 (1936), No. 10, pp. 789-800, fig. 1*).—In studies conducted by the Pennsylvania Experiment Station, no relation was observed between the iodine content of potatoes, tomatoes, and sweet corn and the fertilizer treatment, soil acidity, or yield. An application of potassium iodide at the rate of 2.356 kg per acre, equivalent to approximately 2 mg of iodine to each kilogram of soil in the upper 6 in., increased the iodine content of green beans considerably but injured the plants and reduced yields. Similar applications to turnips increased yields somewhat and increased the iodine content 10- to 120-fold. The maximum increase in iodine content occurred on plats rendered alkaline by hydrated lime and the minimum on plats acidified with sulfur or unmodified in acidity. The maximum recovery of applied iodine by turnips was 11.4 percent. Analyses of turnips grown the next year without further iodine application indicated that there is no residual effect. In general, the iodine content of turnips from soil not fertilized with potassium iodide increased with the acidity of the soil. Under the same conditions, the iodine content of beans was little affected.

**Early tomatoes**, W. T. TAPLEY (*Farm Res. [New York State Sta.], 3 (1937), No. 2, p. 4*).—Brief descriptive notes are presented on a large number of early maturing varieties of tomatoes tested at the station.

**[Pomological investigations by the Cornell Station]** ([*New York*] *Cornell Sta. Rpt. 1936, pp. 126-129*).—Progress statements are presented on soil factors associated with significant difference in yield behavior of important fruit crops, by J. Oskamp, A. J. Heinicke, and D. Boynton; effect of careless handling on the keeping quality of apples, and effect of washing for spray-residue removal on bruising and on storage quality of apples, both by E. L. Overholser and M. B. Hoffman; the best distribution for pollinizer trees in the orchard to give satisfactory set of fruit on McIntosh, by L. H. MacDaniels; effect on the set of fruit of spraying and dusting apple blossoms with various fungicides and bactericides, by MacDaniels and E. M. Hildebrand; an anatomical study of fruit trees injured by low temperatures during the winter of 1933-34 (with the purpose of correlating the nature and amount of the injury with the recovery of the tree), inarching and bridge grafting as a means of saving trees with crowns wholly or partly girdled by winter injury or other agents, and propagation of superior native nut varieties, all by MacDaniels; influence of age and condition of trees on their response to pruning and response of young fruit trees to annual pruning as compared with pruning repeated at intervals of two years or longer, both by Heinicke and MacDaniels; influence of time of harvest on the keeping quality of Cortland and McIntosh apples, by Heinicke and E. F. Savage; the photosynthetic efficiency of apple foliage under natural conditions, by Heinicke and N. F. Childers; root growth in apple trees, by Heinicke; and influence of food manufactured by leaves of the Northern Spy apple on the fruit characters of the McIntosh apple, by Heinicke.

**The effect of orchard plants on subsoil moisture, C. C. WIGGANS** (*Amer. Soc. Hort. Sci. Proc.*, 32 (1935), pp. 103-107, fig. 1).—Examinations by the Nebraska Experiment Station of soil samples collected at various depths in the vicinity of 17-year-old apple trees spaced 30 by 33 ft. with filler present in part of the orchard showed that 85 percent of all the available moisture from the fifth to the thirtieth foot had been exhausted by the trees in the filler section. In the absence of fillers, the trees had used approximately 65 percent of the available moisture. In a second study in which samples were taken 1.5, 15, and 22.3 ft. from the trunk, it was found that the depletion was greater nearer the trunks. Observations of samples collected beneath grapes which had been mulched continuously for 10 yr. or more and beneath clean cultured vines showed that mulching is very effective in conserving moisture. Observations on soil moisture in a white pine forest following the death of the trees from drought and a year later after a seasonal rainfall of 30 in. showed a great improvement in soil moisture conditions.

**Some problems in the use of superior rootstocks for fruit trees, J. A. MCCLINTOCK** (*Amer. Soc. Hort. Sci. Proc.*, 32 (1935), pp. 329-331).—Investigations by the Indiana Experiment Station at La Fayette and Mitchell show that various varieties of apples after becoming established on their own roots are superior to the same varieties on French Crab. Virginia Crab was found fairly resistant to woolly aphis under Indiana conditions. Grimes Golden on own-rooted Virginia Crab suffered no mortality from collar rot. The method of top-working young apple trees is discussed.

**What yield of rooted shoots may be expected from mother plantations of Malling apple and quince rootstocks? H. B. TUKEY and K. D. BRASE** (*Amer. Soc. Hort. Sci. Proc.*, 32 (1935), pp. 338-345, figs. 3).—In studies at the New York State Experiment Station in which various Malling rootstocks were propagated by mound and trench layering according to their inherent vigor, it was found that under good cultural conditions Malling apple and quince rootstocks may be expected to yield sufficient new plants to make their propagation commercially feasible. The number of rooted shoots obtained per unit area increased for several years after the establishment of the beds, but the percentage of well-rooted salable shoots varied from year to year with the growing conditions. Quince rooted more readily than apple, Malling I and IX rooted easily, II rooted well, followed in descending order by XIII, XII, and XVI. The apples were not injured appreciably by extreme low winter temperatures, but quince, from which salable shoots were removed in the fall, suffered severe damage.

**The Malling clonal stocks in relation to McIntosh and Wealthy, J. K. SHAW** (*Amer. Soc. Hort. Sci. Proc.*, 32 (1935), pp. 346-349).—In 1924 the Massachusetts Experiment Station imported many of the Malling stocks, and after budding them to McIntosh and Wealthy planted the trees in orchard form in 1928 with seedling-rooted and own-rooted trees as checks. Records on the orchard showed that production was correlated with tree size, and only I and IV, when grafted to McIntosh, tended to promote early bearing. Wealthy was more variable on seedlings than on any clon, but McIntosh was less variable only on XVI. There was some suggestion that McIntosh on certain clons may hold its fruit better near harvest time. In some cases, the stocks seemed to influence the shape of the apples. On a basis of productivity, Malling XII and possibly XVI were better than seedlings or own roots for both Wealthy and McIntosh.

**Studies in incompatibility of stock and scion.—I, Information accumulated during twenty years of testing fruit tree rootstocks with various scion varieties at East Malling, J. AMOS, T. N. HOBLYN, R. J. GARNER, and**

A. W. WITT (*East Malling [Kent] Res. Sta. Ann. Rpt.*, 23 (1935), pp. 81-99, fig. 1).—The anatomical examination of pieces of root collected from 8- to 10-year-old apple trees revealed a striking difference in the size of the vessels in Malling IX roots and in those developed from the scion. Rootstocks grafted with scions, of which the root structure was very different, appeared to maintain their original structure. An examination of Malling IX rootstocks from trees grown in different soils failed to show that the soil variation had exerted any significant influence on the structure of the root.

A note on the moisture content of the stems of different rootstocks, M. C. VYVYAN (*East Malling [Kent] Res. Sta. Ann. Rpt.*, 23 (1935), pp. 131-133).—Repeated measurements of the moisture content in the stock stem below the bud union in eight kinds of trees developed by grafting Cox Orange Pippin and Lane Prince Albert apple scions on four Malling stocks, Nos. I, II, IX, and XII, showed in every case the least moisture in stock No. II. In most cases the differences were significantly different. The author suggests that the low moisture values in stock No. II may be associated with low conductivity, as reported by Knight (E. S. R., 57, p. 138).

The root systems of some three-year-old trees of Lane's Prince Albert on two selected rootstocks (Malling No. II  $\times$  Northern Spy), H. M. TYDEMAN (*East Malling [Kent] Res. Sta. Ann. Rpt.*, 23 (1935), pp. 107-110, figs. 2).—Comparative measurements of weights of top and roots of 138 3-year-old trees of Lane Prince Albert propagated on two seedling clons derived from crossing Malling II  $\times$  Northern Spy showed the root systems of the two clons to be widely different despite the common parentage. The trees on both root types were slightly larger than trees on Malling II and decidedly less vigorous than trees on Malling XII. The differences between the two clons are conceded to be apparently of genetic character.

A comparison of the top and root growth made by five varieties of apples on seedling and scion roots during five years in the orchard, F. S. LAQASSÉ (*Amer. Soc. Hort. Sci. Proc.*, 32 (1935), pp. 366-371).—Presenting further information (E. S. R., 72, p. 479) on a rootstock experiment established by the Delaware Experiment Station in 1929, the author states that in general the varieties Yellow Transparent, Stayman Winesap, Delicious, Grimes Golden, and Rome Beauty in their first five years in the orchard made a greater net growth of roots and tops on seedlings than on their own roots. Marked differences between varieties, irrespective of the type of root, indicated that the scion controlled largely the amount of growth. At the end of five years, the variability of the net growth made by the scion-rooted trees was less than that of seedling-rooted trees in four of the five varieties, but not significantly so. The top/root ratio of the seedling trees was generally less than that of the scion-rooted trees. In general, tops weighed about twice that of roots.

Crotch angles as affected by the method of training young apple trees, L. P. BATJER (*Amer. Soc. Hort. Sci. Proc.*, 32 (1935), pp. 36-38).—In experiments at Kearneysville, W. Va., three types of training—heading at 30 in., group disbudding, and single disbudding—were compared on vigorous 1-year-old Rome Beauty, Delicious, and Stayman Winesap trees planted in the spring of 1931. In the spring of 1935, crotch angles were measured on 3 or 4 limbs of each tree. On the basis that an angle of less than 40° with the trunk indicates a weak crotch, it was found that the second two treatments produced weak trees in Rome Beauty. The same tendency to a lesser degree was observed in Delicious. In Stayman Winesaps, all treatments gave satisfactory angles, but the same trends were again observed. The author concludes that disbudding is a suitable treatment for naturally spreading varieties such as Jonathan and Stayman Winesap, but that for upright growers a sufficient number of shoots should

be left the first season to permit a desirable selection of crotch angles. Increase in trunk growth was comparable in all three groups with no significant differences either in the first or fifth growing seasons.

**Trunkless apple trees**, A. F. YEAGER (*Amer. Soc. Hort. Sci. Proc.*, 32 (1935), pp. 39, 40).—Observations in 1935 in an orchard of Hibernial apples planted at the North Dakota Experiment Station in 1920 with part of the trees in standard form and part trunkless, showed 70 percent mortality in the standard trees as compared with none in the trunkless group. The surviving standards were significantly smaller and had yielded less fruit.

**Apple leaf structure as related to position of the leaf upon the shoot and to type of growth**, F. F. COWART (*Amer. Soc. Hort. Sci. Proc.*, 32 (1935), pp. 145-148, figs. 3).—Structural comparisons of leaves taken from comparable positions on vigorous spurs and shoots showed certain differences associated with position. Leaf thickness decreased from the base toward the median portion of the shoot and increased thence to the apex. In general, the palisade cells occupy a greater percentage of the mesophyll tissue as the leaves approach the apex. Stomatal frequency increased usually progressively from leaf to leaf from the base to the apex. The size of the stomata was inverse to their number. McIntosh, Cortland, Delicious, and Northern Spy had 350, 351, 411, and 448 stomata per square millimeter. Stomatal frequency varied on portions of a single leaf. As contrasted with leaves on spurs, particularly fruiting spurs, shoot leaves tended to be thicker and larger.

**A comparison of three methods of measuring photosynthetic activity of apple leaves**, W. F. PICKETT (*Amer. Soc. Hort. Sci. Proc.*, 32 (1935), pp. 152-154).—Continuing studies (E. S. R., 74, p. 202), the author discusses results secured by the Kansas Experiment Station in comparing three methods, (1) that of Heinicke and Hoffman, (2) determination of the organic substances formed or the dry matter accumulated by a unit of leaf in a given period, and (3) comparisons at different times of day of the total acid hydrolyzable carbohydrates for measurements of photosynthetic activity. No two methods gave the same results, principally because they do not measure the same activities. In the case of Delicious a greater gain per unit area was shown with the dry weight increment method than with the other two.

**The effect of flotation sulphur spray on the CO<sub>2</sub> assimilation of apple leaves**, E. P. CHRISTOPHER (*Amer. Soc. Hort. Sci. Proc.*, 32 (1935), pp. 149-151).—After collecting data in the orchards of the Rhode Island Experiment Station on the carbon dioxide assimilation of McIntosh apple leaves over two 4-hr. periods, half were sprayed on both surfaces with flotation sulfur paste. There was a higher assimilation by the sprayed leaves in the morning and a lower rate in the afternoon than was indicated by the unsprayed controls. On the basis of six runs twice daily for three successive days after spraying, the assimilation by the sprayed leaves was about 79 percent that of the unsprayed. In the case of small Baldwin trees growing in the greenhouse, the daily average assimilation was lower in the case of sprayed than unsprayed leaves. The average for six runs showed about 82 percent assimilation for the sprayed as compared with 100 percent for the unsprayed leaves.

**To what extent is the McIntosh apple influenced by the food materials synthesized by Northern Spy leaves?** A. J. HEINICKE (*Amer. Soc. Hort. Sci. Proc.*, 32 (1935), pp. 336, 337).—In line with a previous study (E. S. R., 60, p. 142), McIntosh branches located on a tree which had been partially top-worked with Northern Spy were defoliated soon after petal fall to one leaf per fruiting spur. One McIntosh branch was ringed near its base. Practically no bloom was produced by the Northern Spy branches although before defoliation Northern Spy foliage constituted more than 90 percent of the total. The

McIntosh apple attained a good size and high color about the same time as fruit on adjacent McIntosh trees; however, the fruits ripened much later and remained firmer for a much longer time. The McIntosh apples from the treated branches showed modifications around the calyx and stem end which strongly suggested Northern Spy, and the flavor was also suggestive of a blending between the two varieties.

**Soil nitrate nitrogen determinations following the applications of calcium cyanamide and nitrate of soda to the surface of the soil under apple trees during dry and normal seasons.** R. S. MARSH (*Amer. Soc. Hort. Sci. Proc.*, 32 (1935), pp. 142-144).—In fertility experiments conducted cooperatively with 10 orchardists, the Illinois Experiment Station found from studies of soil samples collected at various dates during the year that nitrate content is higher at certain seasons in the cyanamide plats and at other times under nitrate of soda applications. The cyanamide plats were higher on October 10 and November 15, 1934, and on April 26 and November 15, 1935, whereas the nitrate of soda plats were higher in nitrates on June 13 and 26, July 20, and August 10, 1935.

**The influence of mulching apple trees on the moisture-holding capacity of the topsoil.** D. BOYNTON and L. P. BATJER (*Amer. Soc. Hort. Sci. Proc.*, 32 (1935), pp. 92-94, fig. 1).—Studies at the [New York] Cornell Experiment Station of the soil beneath trees that were mulched with stable manure at the rate of 0.5 ton per tree from 1924 to 1929 and 1 ton per tree from 1930 to 1934, and of soil from trees that were mulched with leguminous hay showed considerable increase in the moisture equivalent of the topsoil beneath the manured trees and beneath trees mulched for 4 yr. with legumes. There was no significant increment following 2 yr. of hay mulching. Composite samples of four borings 6 in. deep were taken beneath each tree.

**The distribution of rain under an apple tree.** R. L. McMUNN (*Amer. Soc. Hort. Sci. Proc.*, 32 (1935), pp. 95-98, fig. 1).—Measurements by the Illinois Experiment Station throughout the growing season of water collected in 20 open cans distributed beneath a 25-year-old Jonathan tree showed, during every rain, less water in the cans 4 ft. from the trunk than those farther distant. The foliage shed considerable rain as indicated by the total water collected by cans directly under the densest part of the branches. Uneven distribution after leaf fall indicated that even the bare limbs deflect rain. The prevailing direction of the wind was an important factor in the distribution of the rain.

**Metaxenia in apples.** B. R. NEBEL (*Jour. Heredity*, 27 (1936), No. 9, pp. 345-349, fig. 1).—In this further report (*E. S. R.*, 72, p. 462) the author reviews the earlier work on the subject and presents some additional information. McIntosh pollinated with Wilson Red June and Bolken yielded fruits alike in weight, seed number, and acidity of the juice, but after 9 mo. of cold storage the McIntosh × Wilson Red June fruits showed only slight internal browning and no decayed spots, whereas in the McIntosh × Bolken group 25 percent of the apples were completely decayed and all others showed considerable internal browning.

**New apple varieties give much promise.** G. H. HOWE (*Farm Res. [New York State Sta.]*, 3 (1937), No. 2, pp. 3, 9).—This, the first of two articles on new apple varieties originated for the most part by the station discusses the characteristics of the varieties and their status at the present time. During the breeding operations at the station, there have been developed a total of 13,049 apple seedlings of which 4,569 have fruited and 81 have been given intensive trials.

**Certain effects of wax treatments on various varieties of apples and pears, R. M. Smock** (*Amer. Soc. Hort. Sci. Proc.*, 32 (1935), pp. 284-289, figs. 2).—Daily determinations by the California Experiment Station, Davis, on Gravenstein and Yellow Newtown apples and Hardy, Bartlett, and Winter Nelis pears dipped in waxed emulsions and held at 67° F. showed a marked retardation in the rate of respiration in all varieties. However, when waxes were applied in sufficient quantity to retard ripening materially, the pears did not ripen normally and failed to develop full color. The flesh of the treated pears took on a noticeable alcoholic flavor. The waxed Gravenstein apples did not ripen as satisfactorily as the controls, but in the case of the Yellow Newtown waxing did not lessen quality until about the twenty-fifth day, and since this variety is consumed while still rather green in color waxing had commercial possibilities.

Studies of the intercellular gases in fruits indicated that covering pears and apples with full strength wax emulsion increased significantly the amount of carbon dioxide in the fruit. The greatest increase in the shortest length of time occurred in the Hardy pear.

**Soil management systems in a young Bartlett pear orchard, F. S. Howlett** (*Ohio Sta. Bul.* 578 (1936), pp. 38, figs. 6).—Of five treatments, (1) cultivation with cover crops, plowed, (2) cultivation with cover crops, disked, (3) grass and straw mulch, (4) bluegrass sod with nitrogen, and (5) alfalfa sod, employed in a young Bartlett pear orchard set out in May 1929 at Strongsville, Ohio, the first was the most effective in promoting growth and yield. The average gains per tree in a cross-sectional area of the trunk for the five years 1931-35 were 5.82, 5.64, 5.41, 3.37, and 2.75 sq. in., respectively. The average weight of prunings per tree for the five years 1932-36 was 54.07, 53.19, 41.40, 9.55, and 5.91 oz., respectively. The trees bloomed first in 1932, those in the cultivated plats bearing the most flowers that year. During the four years 1932-35, the trees of the five treatments averaged respectively, 45.06, 44.76, 43.09, 16.33, and 21.13 lb. of fruit. The average fruit from the mulched trees was larger than in any other treatment.

Low soil moisture was found to be the principal factor limiting the growth of trees in the bluegrass and alfalfa plats, the moisture reaching rather frequently the wilting percentage of 9.5. In the 15 months from May to July over the five years, rainfall was deficient by more than 0.5 in. during eight of the months. Depth of rooting was comparatively shallow in all plats, due to the compact nature of the soil. In the alfalfa plats, the buffalo treehopper contributed also to inferior growth. Since the mulched trees grew and fruited almost as well as the cultivated trees, this system of soil management is said to merit consideration under conditions where low soil moisture is frequently an important limiting factor.

**The response of D'Anjou pears to fertilizers in central Washington, E. L. Overholser and L. L. Claypool** (*Amer. Soc. Hort. Sci. Proc.*, 32 (1935), pp. 299-303).—Studies conducted by the Washington Experiment Station upon young vigorous Anjou pears which had borne two fairly large crops prior to the initiation of the experiment showed nitrogen to be the first limiting factor in growth and production. Yield records did not indicate the same differences between plats as were shown by growth measurements because of the marked variation in yield of individual trees. The results showed no direct response to either phosphorus or potassium applied together without nitrogen or in combination with nitrogen. None of the fertilizer treatments had any significant effect on the incidence of cork spot.

**Devise speedy test for peach seeds**, H. B. TUKEY and M. S. RABBITT (*Farm Res. [New York State Sta.]*, 3 (1937), No. 2, p. 10, fig. 1).—This is a popular presentation of material from a previously noted paper (E. S. R., 75, p. 783).

**Types of varietal hardiness in the peach**, M. A. BLAKE (*Amer. Soc. Hort. Sci. Proc.*, 32 (1935), pp. 240-244).—Using the terms hardy and hardiness synonymously to indicate capacity to endure an unfavorable environment, the author lists and discusses briefly, with varietal examples, 19 types of hardiness observed by the New Jersey Experiment Stations in the course of many years' work with peaches.

**A fertile type of Hale peach found in central Georgia**, W. D. ARMSTRONG (*Amer. Soc. Hort. Sci. Proc.*, 32 (1935), pp. 290-292).—Observations by the Georgia Experiment Station in an orchard of 5,000 Hale trees near Experiment revealed some trees with wide-open blooms containing an abundance of bright yellow pollen. The fruit on these trees ripened from 3 to 5 days later than Hale and appeared to be intermediate in character between Hale and Elberta. Under cheesecloth cages flowers of the aberrant trees set a good crop when self-pollinated, while under the same conditions Hale trees set only buttons. In a 12-percent sugar solution at 80° F. pollen of the new strain germinated 40 percent as compared with 11 for Elberta. The pollen of the new strain, Georgia Hale, gave good sets of fruit on other varieties, and the new peach is considered promising as a substitute for the original Hale.

**Peach tree abnormalities developing from applications of nitrogen fertilizers alone**.—Preliminary report, E. H. RAWL (*Amer. Soc. Hort. Sci. Proc.*, 32 (1935), pp. 293-298).—Observations in a 14-year-old Elberta peach orchard near Inman, S. C., supplemented with data from experimental fertilizer plats, indicated that for the proper development of cover crops and the foliage, twigs, and fruit, nitrogen alone was not an adequate fertilizer. With nitrogen alone 84.6 percent of the fruits were below 2 in. in diameter, while with an NPK material plus dolomitic limestone 98.2 percent of the peaches were above 2 in. Total yields were greatly increased by the complete fertilizer.

**Nodal development of the peach shoot as related to fruit bud formation**, M. J. DORSEY (*Amer. Soc. Hort. Sci. Proc.*, 32 (1935), pp. 245-257, figs. 27).—Studies at the Illinois Experiment Station of the nodal development in peach shoots grown under different conditions resulted in the proposal of five classes of the nodal growth pattern as follows: (1) A primary leaf without an axillary growth, (2) a single primary leaf but bearing either a fruit or a leaf bud located centrally in the axilla and subtended laterally by scalelike structures in the secondary position, (3) a primary leaf with various combinations of leaf buds and fruit buds in the axil of the greatly reduced secondary structures and in the central position, (4) a primary leaf and one or two leaves in the secondary position and less frequently a tertiary leaf—the number and arrangement of the fruit buds may be similar to that of (3) or very rarely of (2), and (5) a further development of classes (2), (3), and (4) in which elongation of the leaf buds occurs during the current season forming a lateral of varying lengths.

Fruit bud initiation appeared to be determined by the growth conditions prevailing during the early succulent stages of the different parts of the shoot.

**Peach thinning investigations**.—V, A study of late thinning, M. J. DORSEY and R. L. McMUNN (*Amer. Soc. Hort. Sci. Proc.*, 32 (1935), pp. 280-283).—Continuing fruit thinning studies (E. S. R., 69, p. 657), small plats in a block of vigorous 8-year-old Gage peach trees were thinned on June 28, July 5, 13, 19, and 30, and August 10 and 21, respectively. At each thinning date there were

removed respectively, on the average, 704, 551, 567, 424, 485, 449, and 355 fruits per tree. At harvest the trees in each treatment yielded an average of 245, 257, 221, 220, 242, 207, 214, and 170 lb. of fruit. The percentages of fruits 2.75 in. or more in diameter were 27, 29, 27, 26, 28, 31, 43, and 31, respectively. Delayed thinning increased the percentage of larger fruits, apparently both by eliminating the smaller sizes and by stimulating development in the remaining fruit. Under favorable growing conditions the control trees, or those with heavier crops, tended to size up fruits and partly offset the differences secured by thinning.

**The relation of soil moisture to plant growth, illustrated by moisture meter experiments with strawberries, W. S. ROGERS** (*East Malling [Kent] Res. Sta. Ann. Rpt.*, 23 (1935), pp. 111-120, figs. 9).—Using a metering instrument designed to give a continuous reading on soil moisture conditions by indicating the capillary pull or suction force of the soil, the author established, in experiments with strawberries in pots and frames, certain minima below which the moisture content should not be permitted to decline if the plants are expected to thrive.

**Relation of leaf area to berry production in the strawberry, B. B. SPROAT, G. M. DARROW, and J. H. BEAUMONT** (*Amer. Soc. Hort. Sci. Proc.*, 32 (1935), pp. 389-392).—Investigations conducted by the U. S. Department of Agriculture at three different locations with eight varieties of strawberries showed at each location a definite positive correlation between the number of leaves per plant in the autumn and the number of flowers and fruits developed in the next season. In the case of potted Howard 17 plants defoliated to 1, 2, 3, 4, and 5 leaves, the flowers per plant were 3.1, 4.6, 6.6, 7.4, and 8.1, respectively, with 10.8 for the control plants. Apparently the larger the leaf area during the autumn when fruit buds were forming the larger the crop the next spring. A varietal difference was indicated in the fact that 8- and 10-leaved plants of Bellmar, Dorsett, Blakemore, and Fairfax averaged, respectively, about 4.7, 5.1, 7.0, and 8.2 berries per leaf.

**Temperature in relation to the alternate bearing behavior of the Fuerte avocado variety, R. W. HODGSON and S. H. CAMERON** (*Amer. Soc. Hort. Sci. Proc.*, 32 (1935), pp. 55-60, figs. 2).—An analysis of yield records taken over a period of years by the University of California at Los Angeles on a total of 598 trees distributed in 5 orchards yielded further evidence (E. S. R., 73, p. 617) on the existence of alternate bearing in the Fuerte avocado. In none of the 10 groups of similar behavior found in the 5 orchards were two heavy crops borne in succession. The larger the crop of any one season, the greater was the certainty of an ensuing small crop. Of the entire group of 598 trees scattered over an area more than a hundred miles long, 32.2 percent alternated in yield regularly throughout the period of record. Temperature during the blooming period was an important factor in maintaining or disrupting the alternate bearing tendency.

**Effect of soil temperature on growth of citrus, F. F. HALMA** (*Amer. Soc. Hort. Sci. Proc.*, 32 (1935), pp. 67-69).—Observations on rooted cuttings of Eureka lemon, Marsh grapefruit, and Valencia orange planted in frames at the California Citrus Experiment Station, the temperature of the soil of which was modified by electric cables under thermostatic control, indicated that the three species may have different optimum temperature requirements. Lemons, which made the greatest growth of all the species at all three temperatures, grew best at the highest range, 61° to 81° F. Oranges and grapefruit made their maximum growth in the range 54° to 72°. All three species grew least at the lowest range, 37° to 68°.

**Chemical composition in flowers of citrus varieties**, A. R. C. HAAS (*Amer. Soc. Hort. Sci. Proc.*, 32 (1935), pp. 61-66).—Presenting in tabular form the results of analysis at the California Citrus Experiment Station of whole and portions of the flowers of lemon, orange, and grapefruit, the author points out the probability that when citrus trees bloom heavily and drop many of their flowers there is a considerable loss of inorganic and organic constituents, despite the fact that before leaves or flowers drop a considerable portion of their chemical constituents probably moves back into the tree. Among constituents considered were water, ash, calcium, magnesium, potassium, sodium, reducing and nonreducing sugars, and pectin. There was a considerable content of total pectin in the blooms.

**Seasonal changes in the nitrogen content of citrus fruits**, S. H. CAMERON, D. APPLEMAN, and J. BIALOGLOWSKI (*Amer. Soc. Hort. Sci. Proc.*, 32 (1935), pp. 87-89, figs. 4).—Continuing studies by the University of California at Los Angeles, on the use of nitrogen by the citrus tree (E. S. R., 73, p. 617), the authors present the results of analyses of lemons, oranges, and grapefruit harvested at biweekly intervals from early stages to several weeks after the commercial harvesting. In all three species, the amount of nitrogen in the whole fruits increased steadily throughout the period of collection. Until early autumn the rinds contained more than half the nitrogen. The analyses showed that if Valencia oranges are left on the trees as long as they will adhere they contain 20 to 25 percent more nitrogen than when picked at commercial maturity. The possible harmful effect of this continued use of nitrogen on the next crop is discussed.

**The apparent growth rate of lemon fruits as an index of the moisture supply of the tree**, J. R. FURR and C. A. TAYLOR (*Amer. Soc. Hort. Sci. Proc.*, 32 (1935), p. 70).—Applying three irrigation treatments, (1) so frequent that apparent growth rates were never limited, (2) when apparent fruit growth had ceased or when the trees began to show serious defoliation, and (3) when the first significant decrease in apparent growth rate occurred, there was observed at harvest no significant differences in the size of fruit from the first and third treatments either on medium or heavy soil. On light soil, the first treatment resulted in slightly larger fruits than the third. On all three soils the fruits of trees receiving the second irrigation treatment were much smaller than those on the first and third.

**The effect of decreasing soil moisture supply on size of lemon fruits**, C. A. TAYLOR and J. R. FURR (*Amer. Soc. Hort. Sci. Proc.*, 32 (1935), pp. 71-81, figs. 10).—Correlating soil moisture records with tree response as measured by size of fruit, it was found in these studies conducted by the U. S. Department of Agriculture that when the first indications of water deficit appeared in the fruit the major part of the roots was in soil which was below the half point on the scale of available moisture. Moisture content was above that at which sunflowers showed the first sign of wilt. When moisture deficit stopped further growth of large fruits, all of the upper 2 ft. of soil was below the point of the first wilting of sunflowers.

**A progress report of fertilizer studies with grapefruit in the Salt River Valley, Arizona**, A. F. KINNISON and D. W. ALBERT (*Amer. Soc. Hort. Sci. Proc.*, 32 (1935), pp. 90, 91).—Based on 4-yr. studies with mature Marsh grapefruit trees, the Arizona Experiment Station reports that annual applications of available phosphorus supplementing stable manure increased the yield and quality of fruit and tree growth. Supplementary applications of nitrogen or of stable manure tended to lower the grade of fruit and reduced yields. Potash was beneficial to the extent of maintaining previous performance and promoting a better grade of fruit than that of the control trees.

**Metaxenia and interspecific pollinations in Phoenix**, R. W. NIXON (*Amer. Soc. Hort. Sci. Proc.*, 32 (1935), pp. 21-26, fig. 1).—Following an earlier paper (E. S. R., 73, p. 482) on metaxenia induced by pollen of male varieties of the species *P. dactylifera*, the author presents the results secured with pollen of other species of *Phoenix* applied to the flowers of Deglet Noor and other commercial dates.

*P. canariensis* pollen produced consistently later maturing fruits, in some cases even later than those obtained with any *P. dactylifera* pollen tested. The set of Deglet Noor averaged less than that obtained with *P. dactylifera* pollen, a result conceded due possibly to the necessity of storing the *P. canariensis* pollen 1 or 2 mo. before use. *P. canariensis* pollen gave better sets on Khars than it did on Deglet Noor. *P. roebelenii* pollen induced very late maturity in the Deglet Noor. Results with *P. sylvestris* were very similar to those with *P. dactylifera*, suggesting a close relationship between the two species. *P. reclinata* pollen produced consistently late ripening Deglet Noor dates, and it is deemed possible that this species may have value in commercial date culture where early maturity is disadvantageous.

**Growth rate of Deglet Noor dates in metaxenia**, C. L. CRAWFORD (*Amer. Soc. Hort. Sci. Proc.*, 32 (1935), pp. 51-54, fig. 1).—Periodic measurements in the U. S. Date Garden, Indio, Calif., of dates resulting from controlled pollinations with males known to produce metaxenial effects showed that the metaxenial effect appears early in the development of the fruit and seeds. Slight differences appeared early and increased until correlated with significant differences at the time of maximum size.

**Field and laboratory studies on the behavior of NH<sub>4</sub> fertilizer with special reference to the almond**, E. L. PROEBSTING (*Amer. Soc. Hort. Sci. Proc.*, 32 (1935), pp. 46-50, fig. 1).—The results of experiments conducted by the California Experiment Station at Davis with Ne Plus Ultra almonds growing in the western part of the Sacramento Valley, where rainfall averages about 15 in. and falls almost entirely between October and May, showed that applications of ammonium sulfate at the rate of 10 lb. per tree per year promoted growth, larger leaf surface, longer retention of leaves, greater resistance to red spider, and larger yields. The application of irrigation water in later years improved growth and yield of the entire orchard and reduced further the injury from red spider. Nitrogen was even more beneficial under irrigation. Laboratory studies on the penetration of ammonium sulfate into various soils indicate nearly complete fixation in the surface layers.

**Influence of pruning and applications of ammonium sulphate on the growth, pistillate bloom and set of nuts on pecan trees**, H. L. CRANE and F. N. DODGE (*Amer. Soc. Hort. Sci. Proc.*, 32 (1935), pp. 42-45).—The results of a study begun in 1931 near Albany, Ga., in a 10-year-old Schley orchard, the trees of which were vigorous and bearing fair crops of nuts, showed that terminal shoot growth and the formation of pistillate flowers were stimulated by applications of ammonium sulfate or pruning, or both. In addition, the percentage of pistillate clusters which set nuts and the number of nuts per cluster were significantly increased by the fertilizer. Pruning alone resulted in almost twice and pruning plus fertilizer more than thrice as many nuts per shoot as compared with untreated trees.

**[Ornamental horticulture studies by the Cornell Station]** ([*New York Cornell Sta. Rpt.* 1936, pp. 109, 110).—Studies are briefly discussed on problems in the culture of hydrangeas, by R. C. Allen; and photoperiodism of the china aster, effects of temperature and length of day on euphorbia, effects of varying temperatures on certain greenhouse plants, and relation between storage temperature and forcing of narcissi, all by K. Post.

**Factors associated with bud-drop of sweet peas, and a method of controlling it.** R. B. FAENHAM (*Florists' Bsch. and Hort. Trade World*, 86 (1936), No. 19, pp. 18, 19, figs. 2).—At the New Jersey Experiment Stations sweet pea plants grown in jars of coarse, washed sand were supplied beginning October 1 with complete nutrient solutions in 4 different concentrations, namely, 0.5, 1, 2, and 3 atmospheres. The plants in the 0.5 and 1 atm. were similar in growth and were classed as low concentration plants as contrasted with high concentration plants for 2 and 3 atm. Daily records during December and early January showed as high as 100 percent bud drop during cloudy periods in the low concentration group, whereas at the same time the high concentration plants held sufficient buds to yield a fine Christmas crop of blooms. Flower yields from October 23 to February 1 showed average total yields of over 50 flower-bearing stems per plant in the high concentration group as compared with something over 30 for the low concentration group. A tabular summary is presented of the effects of the different concentrations on root, plant, and leaf development.

### FORESTRY

[Forestry investigations by the Cornell Station] ([*New York*] *Cornell Sta. Rpt.* 1936, pp. 79, 111, 112).—Brief notes are given on the calcium requirements of different tree species and the correlation between this factor and the ecological distribution of species, by R. F. Chandler, Jr.; improved practice in the production of forest planting stock of broad-leaved timber-tree species, by J. N. Spaeth and M. Afanasiev; establishment, culture, and development of forest plantations, by Spaeth; and some relationships between forest-tree rooting, and soil type, ground-water level, and soil temperature, by Spaeth and C. H. Diebold.

**Relation of soil character as expressed by certain soil types to the choice of land for forestry in the cut-over pine lands of northern Michigan.** R. L. DONAHUE (*Amer. Soil Survey Assoc. Bul.* 17 (1936), pp. 79, 80).—Of eight soil types in northern Michigan where the dominant virgin species was pine, Ogemaw sandy loam and Roselawn sandy loam soils were rated as first-class pine land; Roselawn sand, Rubicon sand, and Bridgman fine sand soils were second class; and Saugatuck sand, Wallace fine sand, and Grayling sand soils were third class. In general, a sandy loam texture contributes toward making a good pine site and hardpan or coarse dry soil tends toward a poor site.

**Soil characteristics in relation to the occurrence and growth of black spruce.** R. H. WESTVELD (*Amer. Soil Survey Assoc. Bul.* 17 (1936), pp. 45-47, figs. 2).—Studies by the Michigan Experiment Station on the occurrence and growth of black spruce in relation to certain soil characteristics showed that soil moisture plays an important part in the distribution of this species. Although tolerating wet soil, growth was inferior in such locations. In general, for both mineral and organic soils, black spruce grew most rapidly where it was rather poorly represented in the stand, suggesting the desirability of favoring this species in selective cuttings, especially when the associates were of inferior commercial value.

**Soil changes associated with forest fires in the longleaf pine region of the South.** F. HEYWARD (*Amer. Soil Survey Assoc. Bul.* 17 (1936), pp. 41, 42).—Observations over an extended area from Georgia to Louisiana indicated that soils protected from fire are much more penetrable and porous than those subjected to fire. Burned-over soils showed a slightly higher ignition loss, probably due to charcoal. In addition, they contained more replaceable calcium and probably other ash constituents and were, therefore, slightly less acid. They also contained a higher percentage of total nitrogen. There was no evi-

dence that severe soil degradation follows periodic fires nor, on the other hand, that the soils of the region are benefited definitely by fires.

**Trends in the nitrogen, phosphorus, potassium, and calcium content of the leaves of some forest trees during the growing season.** H. L. MITCHELL (*Black Rock Forest Papers*, 1 (1936), No. 6, pp. 30-44, figs. 6).—Observations on leaf samples collected in late May, June, July, August, and September from trees of white, chestnut, and red oaks, shagbark hickory, sugar and red maples, and Norway spruce showed that the leaves of deciduous species continue to gain in weight as long as they remain green. The trends in moisture content were opposite to those of dry weight. The concentration of nitrogen, phosphorus, and potassium in the leaves of all species decreased quite rapidly during the period of greatest leaf growth but tended to become relatively constant in the month previous to yellowing. At the same time, the absolute amount of N, P, K, and Ca in the leaves increased as the season advanced, attaining a maximum just prior to the change in color in autumn. Migration of N, P, and K from the leaves back into the conducting tissues of the trees was observed after the leaves began to yellow, but there was no evidence of any such movement as long as the leaves were green and vigorous.

**The relative feeding power of oaks and maples for soil phosphorus.** H. L. MITCHELL and R. F. FINN (*Black Rock Forest Papers*, 1 (1935), No. 2, pp. 5-9, fig. 1).—Data obtained on the phosphorus content of the leaves of white oak, chestnut oak, and sugar maple growing on experimental fertilizer plats showed that phosphorus absorption tends to vary between genera but not between species. It was strongly indicated that the maple has a greater feeding power, at least for soil phosphorus, than has the oak.

An introduction by A. C. Cline is included.

**Nutritional studies on loblolly pine.** R. M. ADDOMS (*Plant Physiol.*, 12 (1937), No. 1, pp. 199-205, figs. 2).—Experiments at Duke University with seedlings grown in sand cultures showed that the loblolly pine is able to utilize nitrogen either as nitrate or ammonium. Alteration of the acidity over a wide range revealed the best development in the case of calcium nitrate when the solution was decidedly acid and in the case of sulfate of ammonia when the solution was more nearly neutral. The young trees compared favorably with those growing in soil except that there was a yellowing of the foliage from time to time in both series due, apparently, to temporary deficiency in available nitrogen. The failure of mycorrhiza, present when the seedlings were set out, to develop to any considerable degree in the sand cultures is believed suggestive of the probability that mycorrhiza are incidental rather than highly beneficial to the loblolly pine.

**The effect of varied solar radiation upon the growth, development, and nutrient content of white pine seedlings grown under nursery conditions.** H. L. MITCHELL (*Black Rock Forest Papers*, 1 (1936), No. 4, pp. 15-22, figs. 2).—The total yield (roots and shoots) of white pine seedlings was found to vary directly with radiation intensity. Over the entire range, including full sunlight, increased light resulted in increased yields. Light variation had a relatively greater effect on root development than on the aerial portion of the plants. The seedlings were grown on a relatively infertile soil and received no other care than weeding and an occasional watering during dry periods.

**A chestnut oak volume table for the Hudson highland region.** H. H. TAYLOR and R. F. FINN (*Black Rock Forest Papers*, 1 (1935), No. 3, pp. 13, 14).—Based on data collected in eight separate cutting operations involving 2,228 trees, there is presented a volume table for chestnut oak. In a field trial the table underestimated the actual cut by about 4 percent.

## DISEASES OF PLANTS

Insect and cryptogamic parasites of fruit, ornamental, horticultural, and agronomic plants. Fungicides and insecticides: Methods of their use against parasites, O. TRAVERSO (*Insetti e orittogame parassiti delle piante da frutto, ornamentali, ortensi e agrarie. Anticrittogamici e insetticidi: Metodi per usarli contro i parassiti*. Roma: P. and A. Ingegnoli, [1935], pp. XV+268, figs. 117).—This is described as a "technical-practical manual for the use of agronomists, horticulturists, and amateur gardeners."

A contribution to the physiology of diseased plants, V. F. KUPREVICH (V. TH. KUPREWICZ) (*Leningrad: Akad. Nauk S. S. S. R., 1934, pp. 71, figs. 11; Eng. abs., pp. 69-71*).—The author reports the results of a series of comparative studies on the physiological processes occurring in healthy v. fungus- or virus-infected plants, including *Cirsium arvense* infected by *Puccinia suaveolens*, field peas by *Mycosphaerella pinodes*, *Trifolium hybridum* by *Erysiphe communis*, and potatoes infected by mosaic, leaf roll, and aucuba viruses. A bibliography of 159 titles is included.

The Plant Disease Reporter, January 15 and February 1, 1937 (*U. S. Dept. Agr., Bur. Plant Indus., Plant Disease Rptr., 21 (1937), Nos. 1, pp. 14, figs. 2; 2, pp. 15-40, figs. 3*).—Among other things of current interest included are the following:

No. 1.—Curly top and other diseases of spinach in Texas, by J. J. Taubenhau and G. E. Altstatt; reducing leaf spot (*Mycosphaerella fragariae*) and leaf scorch (*Diplocarpon earliana*) injury to strawberry calyxes by use of a winter mulch, by J. B. Demaree and M. S. Wilcox; nut diseases (Persian walnut and filbert) in the Pacific Northwest in 1936, by P. W. Miller; downy mildew (*Pseudoperonospora humuli*) of hops in Washington and Oregon in 1936, by G. R. Hoerner; downy mildew of hops in California in 1936, by D. G. Milbrath; *Verticillium* wilt of smoketree (*Cotinus coggygria*), by M. E. Fowler; dodder on peppertrees in California, by G. R. Johnstone; and brief notes on plant diseases (including charcoal rot (*Rhizoctonia bataticola*) on corn in Missouri, by C. G. Schmitt, mosaic on black raspberry in Washington, by G. A. Huber, and rust on greenhouse-grown Clarkias in New York, due to *Pucciniastrum pustulatum*, by P. P. Pirone).

No. 2.—An analysis of volume 20 of The Plant Disease Reporter; notes on the effect of environmental conditions on fruit crop and fruit diseases in the Ozark section in 1936, including observations in (1) Arkansas, by J. C. Dunegan, and (2) Missouri, by M. A. Smith; occurrence of tobacco diseases in Virginia in 1936, by J. A. Pinckard, J. Godkin, and R. G. Henderson; "concealed damage" (due to soil fungi) of runner peanuts in Georgia, by H. W. Rankin; rice kernel smut (*Tilletia horrida*) in Texas, by E. C. Tullis; notes on the stinking smuts of wheat in Turkey in the 1936 crop, by D. P. Limber; crown gall of the fasciated type on *Asparagus sprengeri*, by N. A. Brown and F. Weiss; relative susceptibility of certain varieties of dahlias to root knot nematode (*Heterodera marioni*), by R. Schmidt; and diseases of shade and ornamental trees—summary of specimens received in 1935 and 1936 at the New Haven office, Division of Forest Pathology, by A. M. Waterman.

[Phytopathological studies by the California Station] (*California Sta. [Bien.] Rpt. 1935-36, pp. 23, 66-84*).—Progress reports are given on studies of iron chlorosis of fruits; citrus mottle-leaf—a physiological disease; control of little leaf of deciduous fruit trees; zinc for walnut little leaf; die-back and rosette of apples; prune die-back; black end of pears; fire blight—a bacterial disease; olive knot or tuberculosis; *Coryneum* blight on peaches—a fungus

disease; *Coryneum* blight and blossom blight on almonds; a new root rot (*Rosellinia*) of fruit trees; preventing citrus fruit rots and damping-off; *Dothiorella* rot of avocados; date palm disease (rhizosis, etc.); fungus diseases of vegetables; so-called *Ascochyta* blight of peas; *Fusarium* diseases of vegetables; downy mildew of hops; fungus causing southern root rot of sugar beets; control of southern root rot; peach mosaic—a virus disease; buckskin, a virus disease of sweet cherries; vegetables and ornamentals affected with spotted wilt; transmission of spotted wilt; a new disease of grapevines (unidentified, but possibly of virus etiology); transmission of sugar beet curly top; virus diseases of celery; and mosaic diseases of cauliflower and stock.

**Plant pathology** (*Hawaii Sta. Rpt. 1936, pp. 33-40, fig. 1*).—Progress reports are given on diseases of the taro and their control (including three types of corm rot and diseases of the leaves) by G. K. Parris and F. A. I. Bowers; and diseases and insect pests of tomatoes and truck crops, by Parris. A list of fungus diseases and insect pests noted on various crop plants in Hawaii is included.

**[Phytopathological studies by the Cornell Station]** (*New York Cornell Sta. Rpt. 1936, pp. 92, 115-123, 145, 146*).—Progress reports are given on the following studies: Permanent crop improvement through the control of disease by the development of immune or disease-resistant stocks, and virus diseases, both by D. Reddick; the Dutch elm disease, by D. S. Welch, K. G. Parker, L. J. Tyler, P. A. Read, and D. L. Collins; *Nectria* canker of basswood and other hardwood species, by Welch; studies on species of *Sclerotinia* and related genera in North America—III, *Ciboria accrina* n. sp., by H. H. Whetzel and N. F. Buchwald; diseases of roses, by L. M. Massey, E. W. Lyle, and K. Longree; the cork and rosette diseases of apple, by A. B. Burrell and H. J. Miller; lime-sulfur and substitute fungicides for the control of apple scab and leaf scorch in western New York, by W. D. Mills; overwintering of the fire blight organism in Baldwin apple trees suffering from severe winter injury, by E. M. Hildebrand; the role played by the honeybee and the beehive in the fire blight disease, by Hildebrand and E. F. Phillips; incidence of fire blight in young apple trees in relation to orchard practices at Ithaca, by Hildebrand and A. J. Heinicke; control of onion mildew, and control of *Botrytis* rot of lettuce, both by A. G. Newhall; lettuce yellows and other virus diseases, by M. B. Lun and Newhall; a bacterial leaf spot of geranium (due to *Phytomonas geranii* n. sp.), and a bacterial blight of iris (ascribed to *P. phyllosuavis* n. sp.), both by W. H. Burkholder; a comparative study of some yellow proteolytic bacterial plant pathogens (*Phytomonas* spp.), by C. C. Wernham and Burkholder; a comparative study of some species of *Actinomyces* isolated from scabby potatoes, by C. F. Taylor and Burkholder; diseases of narcissus and other flowering bulbs, by F. A. Haasis, C. E. F. Guterman, and F. Weiss; diseases of cyclamens and other potted plants, by J. M. Bickerton, Guterman, and Massey; aster rust and its control, by Guterman; diseases of lilies, by D. K. O'Leary and Guterman; factors affecting the efficiency of potato spraying, by F. M. Blodgett, E. O. Mader, O. D. Burke, and R. B. McCormack; scab, *Rhizoctonia*, and pitting of potatoes, by Blodgett, Taylor, and E. K. Cowan; potato yellow dwarf, by L. M. Black, K. H. Fernow, and Blodgett; and browning of cauliflower (nonparasitic and controlled by boron applications to the soil), by G. J. Raleigh, W. C. Barnes, and C. H. Dearborn.

**Plant diseases** (*West Virginia Sta. Bul. 278 (1936), pp. 24-27, fig. 1*).—Brief reports are given on the black pox of apple, identified as due to the black root rot fungus; the relationship of the soft rot and colon groups of bacteria; and the influence of growth substances on some 200 representative fungi.

**Report of the plant pathologist: Virus diseases of plants, H. H. STOREY** (*East African Agr. Res. Sta., Amant, Ann. Rpt.*, 7 (1935), pp. 12-16).—Brief notes are given on the mechanism of the transmission of plant viruses by insects and on mosaic disease of cassava.

**The susceptibility of the plant cell to virus disease, F. M. L. SHEFFIELD** (*Ann. Appl. Biol.*, 23 (1936), No. 3, pp. 498-505, fig. 1).—A number of experiments, using the viruses of aucuba mosaic of tomato and mosaic of tobacco sprayed on several host plants, indicated that they could not enter a plant unless some of the cells were injured. It was not essential that injury should accompany the presence of the virus. The chances of infection fell off rapidly in the first few minutes after injury, but infection occurred occasionally as long as  $\frac{1}{2}$  hr. after cell damage. Inoculations by micropipette into single host cells yielded only about one-tenth the expected number of infections, suggesting differences in the susceptibility of the cells to virus attack.

**The role of plasmodesms in the translocation of virus, F. M. L. SHEFFIELD** (*Ann. Appl. Biol.*, 23 (1936), No. 3, pp. 506-508, pl. 1).—A study of epidermal strippings from leaves of tomato, tobacco, *Hyoscyamus niger*, and *Solanum nodiflorum* revealed no protoplasmic connections between the guard cells and the surrounding tissues. Since inclusion bodies have been found in all cells of the epidermis except the guard cells, these findings suggest that owing to the absence of plasmodesms the virus is unable to reach the guard cells. Support is also lent to the view that in the ground tissue of the plant the virus is carried from cell to cell along the protoplasmic bridges.

**Factors affecting the amount of infection obtained by aphid transmission of the virus Hy. III, M. A. WATSON (HAMILTON)** (*Roy. Soc. London, Phil. Trans., Ser. B*, 226 (1936), No. 540, pp. 457-489, figs. 9).—Using the vector *Myzus persicae* of tobacco virus Hy. III and leaves of corresponding age for all feedings, a maximum percentage of infection was obtained during winter and a minimum during summer. The percentage of infection increased with the number of aphids per plant, and the relation between the numbers of infections for each aphid number indicated that infections are local and independent. The percentage of infection increased with increased feeding time on the healthy plant, but there was no indication of a preliminary period in which no infection occurred. The percentage of infection decreased very rapidly with increasing time on the infected plant from 2 min. to 1 hr., but after 1 hr. it increased slightly with further increase in the feeding periods. Uncertainty as to whether aphids had fed on the trial leaves for the exact period allowed was overcome either by "watched feedings" or by allowing an average "penetration time" of 5 min. Penetration time was increased by decreasing the relative humidity of the insectary. *M. persicae* proved capable of infecting two consecutive plants without intervening access to a source of infection, but the number of second infections decreased rapidly with increasing time on the healthy plant and was negligible for 1 hr.

Comparisons are made between this and other viruses which appear to be of the same type, and suggestions are made as to the causes of some effects and the mechanisms of infection which are involved.

**The reaction of the viruses of tomato spotted wilt and tobacco mosaic to the pH value of media containing them, R. J. BEST and G. SAMUEL** (*Ann. Appl. Biol.*, 23 (1936), No. 3, pp. 509-537, figs. 6).—Activity-time curves and activity-pH curves are presented for these two viruses. The results indicated that the spotted wilt virus is rapidly inactivated at and below pH 5 and above pH 10. There was no significant difference in activity over the pH range 6-8.9 for  $\frac{1}{2}$  hr. or a 5-hr. contact. Tests with the mosaic virus indicated that

it is inactivated above pH 8.2 and below pH 2, the extent varying with pH value and being complete at pH 11 and 0.5. There was no significant difference in activity of the virus over the pH range 2-8 in the adjusted suspensions and over the pH range 6-8 in the unadjusted suspensions.

The bearing of the results on various virus problems is discussed, and it is noted that at least in the case of tobacco-mosaic virus they strongly suggest its nonorganismal nature.

**Tumors obtained by inoculation of *Bacterium tumefaciens* into embryos and young plants cultivated aseptically** [trans. title], A. BEETHELOT and G. AMOUREUX (*Compt. Rend. Acad. Sci. [Paris]*, 203 (1936), No. 14, pp. 629-631).—The method of culturing embryos and young plants in aseptic media was used successfully on pea, *Ricinus*, sugar beet, sunflower, tobacco, tomato, and cucurbits. It is believed that this technic offers a means of studying more easily the direct passage of the infective agent (*B. tumefaciens* [= *Phytomonas tumefaciens*]) from plant to plant, the appearance of metastases, and tumor grafts, and of attempting the culture of neoplastic tissues under particularly favorable conditions.

**Successful results from treatment of plant tumors with mitogenetic rays emitted by mosquito larvae** [trans. title], W. STEMPEL, G. v[ON] ROMBERG, and R. ULPTS (*Biol. Zentbl.*, 56 (1936), No. 3-4, pp. 114-116, fig. 1).—Plant tumors induced by *Bacterium tumefaciens* [= *Phytomonas tumefaciens*] were strongly retarded in development by treatment with living larvae of *Corethra plumicornis*, and in 25 percent of the cases these tumors were completely inhibited within the observation time (3 mo.).

**Intraspecific and interspecific aversion in *Diplodia***, P. E. HOPPE (*Jour. Agr. Res. [U. S.]*, 53 (1936), No. 9, pp. 671-680, figs. 2).—In this cooperative study by the U. S. D. A. Bureau of Plant Industry and the Wisconsin Experiment Station, intraspecific aversion was found in *D. zeae* and *D. macrospora* and interspecific aversion between these two species. The stability of the particular aversion reactions of different strains of *D. zeae* was maintained after successive mycelial propagations, through successive pycnidial generations, and through inoculation into ears of corn and subsequent reisolation. It is believed that the differences among the strains are genetic, and that the number of strains of *D. zeae* is very large.

Identification of the strains recovered from ears of corn which had been inoculated with various combinations of mixtures of strains proved that inhibitory effects had occurred, so that usually only one strain of the fungus could be reisolated from an ear. A definite sequence appeared to exist in the inhibitory powers of the strains upon one another. No conclusions were drawn regarding the relationship between the capacity of strains for inhibiting the development of others and their degrees of pathogenicity.

**Morphological aspects of *Gymnosporangium* galls**, P. R. MILLER (*Phytopathology*, 26 (1936), No. 8, pp. 799-801, fig. 1).—The author observed a greater abundance of galls of *G. juniperi-virginianae* on awn-shaped than on scalelike leaves of *Juniperus virginiana*. Stained preparations indicated that the galls in the former case were of leaf origin, whereas those from trees with scalelike leaves were of stem origin.

A technic was developed whereby clearly visible sections of galls in various stages could be made easily and rapidly from fresh material. In this way the method of emergence of the gelatinous spore horns through the tough cortex of the gall was shown to be by means of circular cortex caps, lifted and pushed aside by the emerging spore horns.

**Biological study of *Phoma buxi* and *Strigula buxi***, J. NAHAS (*Etude biologique sur le Phoma buxi et le Strigula buxi*. Thesis, Univ. Genève, 1933,

pp. 63, pls. 2, figs. 19).—The author presents a study of a fungus, *P. busti*, and a lichen, *S. busti*, from box (*Buxus sempervirens*), including the morphology, physiology, cultural characters, and life history of the fungus (which is stated to have no injurious effects on the host), and the morphology, relations of the fungus to the alga, and pathogenic action of the lichen on the host. It is said that in its pathogenesis it resembles the parasitic fungi, but that its action is slower.

North American species of *Sclerotinia* and related genera, III, IV (*Mycologia*, 28 (1936), No. 6, pp. 514–527, figs. 19; 29 (1937), No. 1, pp. 128–146, figs. 18).—In the first of these contributions from Cornell University, *Oiboria acerina* n. sp. is described and illustrated by H. H. Whetzel and N. F. Buchwald. It is reported to be common on *Acer rubrum* and *A. saccharinum* and to have been found on certain other hosts. Its cultural characters and life history are detailed, and notes on related matters are included.

In part 4, by H. H. Whetzel, *Septotinia*, a new genus of the Ciborioideae, and *S. podophyllina* n. comb. are described and illustrated. The conidial stage is reported as pathogenic to leaves of *Podophyllum peltatum*, and the taxonomic relationships, distribution, cultural characters, and life history of the fungus are discussed.

The staining of mycelium in woody tissues [trans. title], S. KOŚCIELNY (*Rocz. Nauk Rolnicz. i Leśnych* (Polish Agr. and Forest Ann.), 36 (1936), No. 3, pp. 496–500; *Ger. abs.*, pp. 499, 500).—Using safranin (alcoholic) and aniline blue, the procedure detailed is said to stain woody tissues red and the non-woody parts and mycelia blue or dark blue.

Zone lines in plant tissues.—III, The black lines formed by *Polyporus squamosus* (Huds.) Fr., A. H. CAMPBELL and R. G. MUNSON (*Ann. Appl. Biol.*, 23 (1936), No. 3, pp. 453–464, pls. 2).—Continuing this series (E. S. R., 71, p. 214), the black lines were found in elm wood and *P. squamosus* was isolated from them and cultured. It is suggested that the black lines or plates form a limiting layer of sclerotiumlike bodies buried in the attacked wood.

Fungicides in relation to foliage injury and fruit yield, A. B. GROVES (*Peninsula Hort. Soc. [Del.] Trans.*, 49 (1935), pp. 58–60).—This contribution by the Virginia Experiment Station briefly discusses the subject, and adds data from a field test as showing higher yields and better retention of foliage with copper and sulfur sprays than with the controls or lead arsenate alone.

Spraying tests with copper fungicides on leaves wettable with difficulty [trans. title], SCHMIDT (*Blumen u. Pflanzenbau ver. Gartenwelt*, 40 (1936), No. 2, p. 20, fig. 1).—The comparative merits of various stickers in spray mixtures are discussed, and favorable results in coverage are reported from the addition of "Tezet" to copper fungicides. How well the mixture will control fungus diseases of such plants as carnations and cabbages must be determined by further tests.

Relative susceptibility of certain species of Gramineae to *Cercospora herpotrichoides*, R. SPRAGUE (*Jour. Agr. Res. [U. S.]*, 53 (1936), No. 9, pp. 659–670).—In this cooperative study by the U. S. D. A. Bureau of Plant Industry and the Oregon, Idaho, and Washington Experiment Stations, field and greenhouse inoculations indicated that a large number of species of cereals and other grasses are susceptible to *C. herpotrichoides*, but most range grasses are sufficiently resistant to avoid serious injury in the field under the semiarid conditions and thin stands of the prairie lands in the Pacific Northwest. *Agropyron* spp., *Bromus tectorum*, and several other grasses have been found infected under natural conditions at the edges of wheat fields infected with *C. herpotrichoides*,

Under optimum conditions for the disease, the greenhouse results indicated that certain late varieties (e. g., Hosar and Hohenheimer), apparently resistant in the field, in reality had merely escaped the disease and were without genetic factors for resistance.

While most wheats gave very little indication of genetic resistance, certain *Aegilops* and *Triticum* species were very resistant and the possibility of the eventual development of resistant wheats by crossing with them is pointed out.

The *Cercosporella* foot rot has apparently been present on native prairie grasses in the Columbia Basin for many years.

**Influence of environment during maturation on the disease reaction and yield of wheat and barley.** B. B. BAYLES (*Jour. Agr. Res.* [U. S.], 53 (1936), No. 10, pp. 717-748, figs. 6).—In this cooperative study by the U. S. D. A. Bureau of Plant Industry and the Wisconsin Experiment Station, seed of four varieties of spring wheat and three of spring barley produced at several experiment stations in the United States and Canada in 1929-30 was tested for reaction to seedling blight (*Gibberella saubinetii*) in the greenhouse at Madison and for reaction to bunt (*Tilletia laevis*) and for yield in field trials at Moccasin, Mont., Madison, Wis., and Aberdeen, Idaho.

Environmental conditions under which the seed was produced affected the reaction to seedling blight in the subsequent crop. A relationship was found between low protein in the seed and high resistance indexes and in some cases between large seed and high resistance indexes, but these factors did not account for all differences. The results suggested that differences of a nutritional or biochemical nature were more important than morphological or size differences in the embryo and endosperm.

The environmental conditions under which the seed was produced also affected the reaction to bunt, but the effects were much less pronounced. A small correlation ( $-0.3036$ ,  $P=0.01$ ) was found between seed size and reaction to bunt, the larger seed producing a lower percentage of infected plants.

Only 3 of 91 seed lots produced under different environmental conditions differed significantly from other seed lots of the same variety in capacity to yield. Statistically significant correlation coefficients were obtained, however, for weight of 1,000 kernels sown and dry weight of 100 seedlings at about the fifth-leaf stage ( $+0.9312$ ,  $P<0.01$  for wheat, and  $+0.8213$ ,  $P<0.01$  for barley) and for weight of 1,000 kernels sown and yield of grain ( $+0.4026$ ,  $P=0.02$  for wheat, and  $+0.4049$ ,  $P=0.05$  for barley).

**Influence of black point disease, seed treatment, and origin of seed on stand and yield of hard red spring wheat.** L. R. WAIDRON (*Jour. Agr. Res.* [U. S.], 53 (1936), No. 10, pp. 781-788).—In studies by the North Dakota Experiment Station, wheat seed with visible infection by *Helminthosporium sativum* produced a crop not appreciably affected in yield or other characters except for a slight difference in seedling stand. The application of Ceresan to diseased seed before planting also had no apparent effect on the yield or other characters, but bunt spores applied to the seed reduced the yield in all cases to a significant degree, the loss in yield of the susceptible Ceres variety being pronounced. Seed grown in the greenhouse (exceptionally heavy in kernel weight) produced decidedly larger yields than other seed tested, the larger yields evidently being due to larger initial and mature stands.

The interlocking type of experiment described was effective in reducing the standard error because of a relatively large number of degrees of freedom, comparatively small experimental differences thus showing significance.

**Effect of vernalization on the incidence of loose smut in wheat.** W. F. HANNA (*Sci. Agr.*, 16 (1936), No. 7, pp. 404-407; *Fr. abs.*, p. 407).—"The effect

of environmental conditions on the development of loose smut of wheat and barley is discussed, and the literature on this subject is reviewed. The incidence of loose smut in artificially inoculated seed of Marquis wheat was not appreciably affected by vernalization."

**Nitrogen utilization by *Ophiobolus graminis*, H. FELLOWS** (*Jour. Agr. Res. [U. S.]*, 53 (1936), No. 10, pp. 765-769).—This is a cooperative investigation by the U. S. D. A. Bureau of Plant Industry and the Kansas Experiment Station.

When sown in synthetic liquid media, *O. graminis* (the cause of take-all of wheat) grew when the nitrogen source was egg albumen, casein, peptone, or nucleic acid, but 45 other sources of organic and inorganic nitrogen proved unavailable and organic and inorganic growth-promoting materials did not render them available. Vegetable media of many kinds favored its growth.

**Pusa 120: A wheat highly resistant to yellow rust, F. J. F. SHAW and B. P. PAL** (*Agr. and Livestock in India*, 6 (1936), No. 2, pp. 202, 203).—Pusa 120, a strain selected from the progeny of a cross between Pusa 52 and the Australian variety Federation, proved very highly resistant in greenhouse tests to the three physiologic forms of yellow rust thus far known in India. Another high yielding strain with considerable resistance is Pusa 165, a cross between Pusa 4 and Federation.

**Role of insects in the distribution of cotton wilt caused by *Fusarium vasinfectum*, J. J. TAUBENHAUS and L. D. CHRISTENSON** (*Jour. Agr. Res. [U. S.]*, 53 (1936), No. 9, pp. 703-712, fig. 1).—In this study by the Texas Experiment Station, the following cotton insects were caged and fed on roots, stems, and leaves, or bolls of cotton infected with typical *Fusarium* wilt: *Melanoplus femur-rubrum*, *M. differentialis*, *Schistocerca americana*, *S. obscura*, and other less abundant grasshoppers; larvae of *Alabama argillacea*, *Laphygma frugiperda*, and *Prodenia ornithogalli*; a number of white grub species; and larvae of *Ataxia crypta*. Viable *F. vasinfectum* was isolated from fecal pellets or entire insects cultured on potato-dextrose agar. It was not recovered from, and was apparently destroyed in, the alimentary tract of wireworms, Collembola, and Japygidae. Viable *F. vasinfectum* was recovered from cultures of the entire insects or of fecal pellets dissected out from the recta of numerous species collected in badly wilted cotton fields. The following insects were found to act as natural carriers: *M. differentialis*, *M. mexicanus*, *M. femur-rubrum*, *Encyrtolophus texensis*, *Spharagemon cristatum*, *Tomonotus aztecus*, *Chortophaga viridifasciata australior*, *Schistocerca americana*, *S. obscura*, *Trimerotropis citrina*, and *Dissosteira carolina*. It still remains to be proved whether the boll weevil can act as a carrier.

Cotton seedlings were successfully inoculated with strains of *Fusarium* isolated from the alimentary tract of insects and with a pure culture of *F. vasinfectum* from infected cotton. *F. vasinfectum* has survived for 15 mo. in fecal pellets from grasshoppers fed on wilt-infected cotton stems and kept dry in the laboratory.

It is suggested that these results may help to explain the occasional finding of infected plants in areas where the disease does not ordinarily occur.

***Sclerospora graminicola* on millet in Minnesota, C. S. WANG** (*Phytopathology*, 26 (1936), No. 5, pp. 462-464, figs. 2).—In this investigation at the University of Minnesota, both primary and secondary infections of downy mildew were found on millet (*Setaria italica*) and on foxtail grass (*S. viridis*) in 1935 at two places in Minnesota. Conidia of *Sclerospora graminicola* formed during both day and night at temperatures of from 17° to 34° C. and relative humidity of from 75 to 100 percent. When old conidiophores were removed, a new crop was formed in from 4 to 6 hr. Conidiophores on *Setaria viridis* were shorter than those on *S. italica*, and the normal and giant conidia on *S. viridis* were

slightly smaller than those on *S. italica*. Conidia usually germinated by producing four bicillate zoospores, which were active for about 30 min. and then became encysted. Germ tubes were formed later, and under suitable conditions infection followed.

**"Running out" of potatoes** [trans. title], E. KLAPP (*Forschungsdienst*, 1 (1936), No. 1, pp. 33-38).—This is a general review, with 38 literature references.

**The viruses causing top necrosis (acronecrosis) of the potato**, F. C. BAWDEN (*Ann. Appl. Biol.*, 23 (1936), No. 3, pp. 487-497).—Top necrosis was induced in different potato varieties by a number of viruses, the reactions of which on a large number of commercial varieties are given, together with some of their properties and the methods of transmission. By grafting and needle inoculating infected potatoes to the varieties Epicure, Arran Victory, President, and Up-to-Date and noting the type of necrotic disease induced, it was possible to distinguish with fair accuracy six viruses, the necrotic reactions to which are tabulated.

**The blackening of the flesh of the potato tuber**, R. J. SCOTT (*Scot. Jour. Agr.*, 19 (1936), No. 2, pp. 180-182).—The formation of melanin in potato tubers, with the resultant darkening of the tissues, may be due to age, frost, high temperatures, etc., and it may be assumed that blackening will occur whenever the tissues are killed by any means other than those which deactivate the enzymes. The experiments described show clearly that blackening may also be due to bruising, and this blackening does not disappear when the tubers are cooked but may even increase.

**Investigations on the nematode disease of potatoes caused by *Anguillulina dipsaci***, E. E. EDWARDS (*Jour. Helminthol.*, 14 (1936), No. 1, pp. 41-60).—From the experiments here described and those reported in the literature for other strains of *A. dipsaci*, it is deemed evident that no chemical treatment of the soil can be recommended as sufficiently practical for commercial adoption. However it was found that elimination of infestation from the soil can be effected by introducing well-planned crop rotations. Extensive observations in infested areas seemed to indicate that the strains of *A. dipsaci* on other crops do not infest potatoes, and that the potato form is so specialized to this host, at least in the regions studied, that any other agricultural crop may be used in the potato rotation. From these observations, 3 yr. are deemed a sufficient interval between potato crops, though cases of satisfactory crops after a 2-yr. rest are known. The possibility of wild hosts would suggest effective weed control between potato crops as an insurance measure.

From the results of field variety trials by the author and others, it would appear that the principal varieties in commercial use are subject to rather heavy attacks. An exception is made for King Edward, which appeared to suffer decidedly less injury than any other common variety. Where rotation on infested land is impractical, the author's results would justify the growing of varieties which can be harvested not later than about mid-August. The crop should then be disposed of as soon as possible or stored under perfectly dry conditions.

Pot infection experiments were not very conclusive as to whether the disease is sufficiently manifest in the aerial parts for its early detection in the growing plant. Definite experimental evidence was obtained that even slightly infested tubers or tuber material can initiate soil infestations.

**Histological and cytological changes in sugar-beet seedlings affected with curly top**, E. ABTSCHWAGER and R. C. STARRETT (*Jour. Agr. Res. [U. S.]*, 53 (1936), No. 9, pp. 657-657, pls. 13).—Early primary disturbances induced by the

virus are limited to the pericycle and immature cambium derivatives. The affected cells and their nuclei hypertrophy (and in this process the latter may expand symmetrically), become irregular, or assume odd shapes. Changes in the affected cells are marked by two phases which usually overlap, their relative duration apparently depending on the age of the cell when infected, its immediate environment, and the degree of initial stimulation. During the first (anabolic) phase there is an increase in nucleolar material and chromatin, accompanied by morphological changes in the latter. The threshold of the second (catabolic) phase marks the beginning of irreversible changes in the nucleus, often characterized by dissolution phenomena and the possible emission of altered chromatin. Nucleolar fragments also find their way into the cytoplasm and remain there unaltered, but often lose their visible identity due to proteolytic cytoplasmic changes. Cytoplasmic changes usually parallel those in the nucleus during the early stages, and later stages are marked either by mere quantitative reduction or by disorganization from local or general proteolysis. Of the two types of cytoplasmic inclusions, the first includes calcium oxalate and leucoplasts, normal to healthy plants but often enormously increased in affected roots. The second type includes structures foreign to healthy cells. Prominent, though transitory, are nucleolar fragments and possibly chromatin extrusions with the chromatin greatly altered. Amorphous precipitates exhibiting great variation in staining reactions are also very common. Though their origin is not always clear, it can be attributed to the disintegration of certain compact inclusion bodies and to local cytoplasmic proteolysis.

Resulting from apparently misdirected differentiation in the maturation of cambium derivatives, sieve-tube-like elements with plastids and slime bodies but without sieve plates are formed. The cell walls become covered with pseudocalculus. The cells of the supernumerary cambiums and their derivatives divide longitudinally, and incomplete longitudinal divisions, resulting in binucleate and multinucleate cells, are common.

**Negative evidence on multiplication of curly-top virus in the beet leafhopper, *Eutettix tenellus*, J. H. FREITAG (*Hilgardia* [California Sta.], 10 (1936), No. 9, pp. 305-342, figs. 10).**—An extensive series of experiments involving controlled management of the vectors and host plants resulted in the development of no direct or indirect evidence of the multiplication of the virus within the vector. On the other hand, considerable circumstantial evidence is presented indicating that the virus does not multiply in the body of this insect.

**The control of heart and dry rot of beets** [trans. title], HILLE (*Zucker-rubenbau*, 18 (1936), No. 2, pp. 30-33, figs. 2).—This is a review of experimental data on this disease, including its control by soil applications of boron.

**Sugar-beet production in California, W. W. ROBBINS and C. PRICE (*Calif. Agr. Col. Ext. Circ.* 95 (1936), pp. 78, figs. 35).**—In this general handbook on sugar beets and their culture, by the California Experiment Station in cooperation with the U. S. D. A. Bureau of Plant Industry, the following phytopathological matters are discussed: Controlling the sugar beet nematode, southern *Sclerotium* root rot, downy mildew, curly top, and the sugar beet leafhopper in relation to curly top.

**Control of sweet potato wilt, T. F. MANNS (*Peninsula Hort. Soc. [Del.] Trans.*, 49 (1935), pp. 46, 47).**—Carrying over in the soil is not as active in sweetpotato wilt as in *Fusarium* wilt diseases of some other crops, but the fungus is carried over internally in the "seed." This contribution by the Delaware Experiment Station therefore recommends the field selection of seed at harvest time or slipping to eliminate this and other diseases.

**Further information relating to the control of Raan in swedes, D. G. O'BRIEN and R. W. G. DENNIS** (*Scot. Jour. Agr.*, 19 (1936), No. 1, pp. 40-46, pl. 1, fig. 1).—"Raan" or boron deficiency disease in swedes was eliminated by 20 lb. of borax per acre applied just prior to sowing.

**Ineffective principle and plant cell in some virus diseases of the tobacco plant, III, T. H. THUNG** (*Tijdschr. Plantenziekten*, 43 (1937, No. 1, pp. 11-32, pls. 5; *Eng. abs.*, pp. 25-28).—Immunity studies, made with the tobacco viruses of ordinary mosaic, white mosaic, severe mosaic, ring spot necrosis, "Vorstenlanden distorting" strain I, and Holmes' distorting strain, indicated four types of antagonism—an equilibrium, a domination, a regulable equilibrium, and a partial overweighting. The rapidity of the antagonistic actions, the direction of virus movement, and the cell conditions in relation to immunity are also treated.

**Stream double refraction of preparations of crystalline tobacco-mosaic protein, W. N. TAKAHASHI and T. E. RAWLINS** (*Science*, 85 (1937), No. 2195, pp. 103, 104).—Previous work by the authors (*E. S. R.*, 73, p. 332) suggested that tobacco-mosaic virus may be composed of submicroscopic rod-shaped particles capable of causing stream double refraction. In this study, from the University of California, crystal preparations made from infective juice by the Stanley method (*E. S. R.*, 73, p. 800) and another method and colloidal solutions of the preparations containing the crystals produced stream double refraction. If the Stanley crystal preparations are pure virus, this behavior indicates that this virus is capable of causing stream double refraction and, when in colloidal solution, is probably composed of submicroscopic rod shaped particles. Studies of the relation of pH to intensity of stream double refraction and to active virus concentration were made, as well as a comparison of the active virus concentration and intensity of stream double refraction in crystal preparations and in unpurified samples. If one assumes that the crystal preparations are pure virus, it follows from the results obtained that a significant portion of the virus in the crystals is inactive.

**Precipitation of the tobacco mosaic virus complex at its isoelectric point, R. J. BEST** (*Austral. Jour. Expt Biol. and Med. Sci.*, 14 (1936), No. 1, pp. 1-13, figs. 2).—The virus of ordinary tobacco mosaic is precipitated from clarified juice of infected plants to various extents at from pH 3 to 4, the maximum occurring at pH 3.4. The precipitate, containing practically all of the virus, constitutes about 0.3 percent of the clarified juice or 3 percent of the total solids of the crude juice. The yield averages 2 mg per cubic centimeter of juice. Relatively stable colloidal solutions of the precipitate were obtained by eluting with buffer solutions at from pH 2.8 to 2.3 and from 4.5 to 7.5. From the evidence as a whole it is concluded that the precipitate constitutes the virus or a complex of the virus with some fundamentally related substance in the juice. Precipitation of the virus from suspensions of the "isoelectric" precipitate in buffer solution of pH 7 takes place in the same way as from the juice, the maximum being at pH 3.4. The juice of tomato plants artificially infected with the same virus behaved in the same way. The isoelectric point of the virus-complex may, therefore, be taken as  $\text{pH } 3.4 \pm 0.1$ . The precipitate gave positive tests for protein, and desiccator-dried samples contained 14 percent nitrogen.

**Interspecific transfer of a gene governing type of response to tobacco-mosaic infection, F. O. HOLMES** (*Phytopathology*, 26 (1936), No. 10, pp. 1007-1014).—A necrotic type of response to infection with tobacco-mosaic virus was introduced by crossing into the species *Nicotiana paniculata*. This was accomplished by transferring a dominant gene *N* (necrosis) from *N. rustica* through repeated backcrosses of the hybrid *N. paniculata* × *N. rustica*, using

*N. paniculata* pollen but retaining in each generation only individuals responding to inoculation by production of necrotic lesions. The necrotic type variety of *N. paniculata* thus produced was self-fertile and, in appearance, resembled the ordinary mottling type *N. paniculata*. In its response to infection, however, it was essentially like *N. rustica*, dying from systemic necrosis if infected when young, localizing virus if infected when old.

**Genes affecting response of *Nicotiana tabacum* hybrids to tobacco-mosaic virus.** F. O. HOLMES (*Science*, 85 (1937), No. 2195, pp. 104, 105).—After transferring a dominant gene controlling necrotic response to tobacco virus 1, distorting strain, to a derivative of *N. paniculata* from *N. rustica* by hybridizing and backcrossing (as noted above), this gene was carried from the former to plants of [*(N. paniculata* × *N. tabacum*) × *N. tabacum*] × *N. tabacum*. A similar gene was transferred from *N. glutinosa* to three generations of hybrids with *N. tabacum*, but because of the sterility of the F<sub>1</sub> generation it was carried beyond this generation only by using *N. digluta*. The work is being continued in the hope of possibly incorporating these necrotic-type genes into strains of *N. tabacum* and producing varieties in which the virus would be unable to maintain itself.

**The isolation of tobacco ring spot and other virus proteins by ultracentrifugation.** W. M. STANLEY and R. W. G. WYCKOFF (*Science*, 85 (1937), No. 2198, pp. 181–183).—A high molecular weight crystalline protein, possessing the properties of ring spot virus and differing markedly from tobacco-mosaic virus protein in its physical, chemical, and serological properties, has been isolated by means of an ultracentrifuge from Turkish tobacco plants diseased with tobacco ring spot virus. Ultracentrifugal methods were also used to demonstrate that high molecular weight proteins are characteristic of other virus diseases. The concentration of the different virus proteins in the host was found to differ greatly, ranging from 1 part per 500 for tobacco mosaic, through latent mosaic and severe etch to ring spot, in which the virus protein occurs in about 1 part per 100,000, and to cucumber mosaic in which it may possibly occur in less than 1 part per million. The quantity ultracentrifuge, used in conjunction with an analytical ultracentrifuge, has proved to be a powerful tool for the concentration, purification, and crystallization of high molecular weight virus proteins, and to be indispensable in the case of unstable viruses existing in low concentration in the host.

**Cabbage yellows presents a serious problem.** O. A. REINKING (*Farm Res. [New York State Sta.]*, 3 (1937), No. 2, pp. 1, 2, 7, fig. 1).—A general discussion of this fungus disease is given with special reference to New York State conditions, including references to losses caused, hosts, and resistant varieties.

**Phytophthora root rot of cauliflower.** C. M. TOMPKINS, C. M. TUCKER, and M. W. GARDNER (*Jour. Agr. Res. [U. S.]*, 53 (1936), No. 9, pp. 685–692, pl. 1, figs. 2).—In this cooperative study by the California and Missouri Experiment Stations, it was found that a root rot of cauliflower due to *P. megasperma* is responsible for losses in the winter cauliflower crop in the coastal districts of California. The disease occurs only where the soil has become waterlogged. It also occurs on cabbage, brussels sprouts, cineraria, and stock.

The outer leaves of infected cauliflower plants show a reddish discoloration, and later the plants wilt rather suddenly. Affected plants are easily pulled, and the basal end of the taproot is found to be rotted to such an extent that the cortex usually sloughs off. The cauliflower fungus is described and compared with isolates from certain other hosts.

Infection was obtained by adding the fungus to the soil of potted cauliflower plants and incubating them outdoors in buckets containing water about 4 in. deep. The incubation period was about 3 weeks. Infection was also obtained

by inoculations of stock, cineraria, and wallflower plants and of ripe tomato fruits. Attempts to infect certain other unwounded vegetables were unsuccessful.

**Control of late blight of celery**, J. K. RICHARDSON (*Sci. Agr.*, 16 (1936), No. 7, pp. 358-364, figs. 3).—These tests were undertaken to compare the effectiveness of certain fungicides in the control of late blight (*Septoria apii* and *S. apii-graveolentis*, the latter the more prevalent and the form here considered) under ordinary conditions in the Niagara Peninsula. Based on the results, the following recommendations are made:

A good copper fungicide should be used—either Burgandy (4-5-40) or bordeaux (4-4-40) mixtures as sprays or monohydrated copper sulfate plus lime (20-40) as a dust. Treatments should be thorough, with several applications before the seedlings are transplanted to the field, and at sufficiently short intervals to keep the new growth covered. Wherever possible, treatments should precede rainy periods. The dust should be applied while the dew is still on the plants. The copper-lime dust was less effective than the two sprays recommended. The sulfur sprays used and the copper carbonate-lime dust had very little value.

**Diseases of hops** [I], E. S. SALMON (*Jour. Inst. Brewing*, 41 (1935), No. 6, pp. 235-237).—A brief summary is given of the salient known facts.

**Fungus and virus diseases of the hop**, II, E. S. SALMON (*Jour. Inst. Brewing*, 42 (1936), No. 4, pp. 184-186).—A brief summary of the salient known facts.

**Tomato sickness in Yorkshire**, L. R. JOHNSON and H. W. THOMPSON (*Jour. Min. Agr. [Gt. Brit.]*, 43 (1936), No. 1, pp. 48-54, figs. 4).—Records of tomato infestation with the nematode *Heterodera schachtii* in Great Britain are comparatively new and largely from Yorkshire. The symptoms are described as on the whole similar to those of potato sickness.

Experiments and observations of the past 7 yr., with special reference to greenhouse culture, appear to indicate the danger of planting tomatoes on potato-sick soil. Laboratory experiments showed that the potato strain can infest tomatoes. Control tests appeared to show that the only completely satisfactory method of soil treatment is that of steam sterilization.

**A new disease of tomato** [trans. title], R. GIGANTE (*Bol. R. Staz. Patol. Veg. [Roma]*, n. ser., 16 (1936), No. 3, pp. 183-198, pl. 1, figs. 14).—The disease studied is characterized by leaf variegation and phloem necrosis. Thus far it has been transmitted only by grafting. It is believed to be of virus origin.

**Pathogenicity tests with *Botrytis* spp. when inoculated into apples**, O. F. SCHNELLHARDT and F. D. HEALD (*Phytopathology*, 26 (1936), No. 8, pp. 786-794, figs. 3).—In this contribution by the State College of Washington, gray mold is reported to cause a destructive apple rot in the State, advancing more rapidly than blue mold in storage and especially prevalent when high rainfall occurs during harvesting. Of the 19 species of *Botrytis* studied by inoculation tests, those of the *B. cinerea* type proved strongly parasitic, the others only weakly so. Recent isolations appeared to be more pathogenic than cultured strains.

**Index to the relative susceptibility of orchard apples to cedar-apple rust**, I. H. CROWELL (*Phytopathology*, 26 (1936), No. 5, pp. 459-461).—Hitherto the relative susceptibility of orchard apples to cedar apple rust has been measured by visual observations or by counts of the number of lesions on the leaves. Since the prevalence of rust varies greatly in different orchards and seasons, the resulting measurements likewise vary. The author bases measurements of relative susceptibility on the number of aecia per lesion on apple leaves. This relatively constant phenomenon, based on the physiological reaction between

host and parasite, makes possible a classification of apple varieties independently of many major environmental variables.

**Study scab resistance in apple varieties**, W. O. GLOYER (*Farm Res. [New York State Sta.]*, 3 (1937), No. 2, p. 11).—A brief progress report is given of 2 yr. of results in an apple scab variety test, using unsprayed orchard trees. Many varieties clearly must be protected by spraying, but a few are listed that appeared to be disease escaping.

**A new disease of the apple**, Y. OTSUKA (*Jour. Hort. Assoc. Japan*, 6 (1935), No. 1, pp. 44-53, figs. 4).—This disease is stated to have been known in Manchuria for some years, though not hitherto reported in the literature. About mid-June the affected fruit become darkened around the apical end and develop surface layers of cork in five more or less regular lines extending over the surface opposite each seed cell. Sometimes the entire fruit takes on a corky appearance and may even crack open. Affected fruits are also elongated and subnormal in size. Diseased branches grafted on healthy stock produced diseased fruit, while the other branches on the same tree developed normal fruit. It is still a question whether the disease is transmissible, and the author concludes that it is probably due chiefly to water loss from the fruit by transpiration.

**Progress report on the investigation of a new peach disease**, E. M. STODDARD (*Conn. Pomol. Soc. Proc.*, 44 (1934), pp. 31-36).—This contribution by the Connecticut [New Haven] Experiment Station reports the results of studies during 1934 relative to the "X" disease. Later results have been referred to (*E. S. R.*, 76, p. 496).

**The distribution, cause, and relative importance of cranberry fruit rots in Massachusetts in 1932 and 1933, and their control by spraying**, H. F. BERGMAN and M. S. WILCOX (*Phytopathology*, 26 (1936), No. 7, pp. 656-664, figs. 2).—Early rots caused the greater part of the spoilage of berries from unsprayed plats of a majority of five bogs investigated during 1932 and 1933, and *Glomerella*, *Sporonema*, and *Diaporthe* were the most important causes. *Sporonema* was much more important than has previously been reported. *Diaporthe* caused a loss of from 18 to 35 percent of the crop from several plats on one bog in 1933. The importance of any given fungus varied independently of that of the others, not only on different bogs but also on different parts of the same bog. A single application of 4-6-50 bordeaux mixture (made up with granular copper sulfate and chemically hydrated lime) was often ineffective and never so effective as were two. With one exception, two and three applications were beneficial on all bogs used in 1932 and 1933, although much variation in the degree of control was observed. In many instances two applications gave apparently as good control as three. Two mercurial sprays (phenyl mercury acetate and ethyl mercury arsenate) used on one bog in 1932 were fully as effective as bordeaux. With reference to the control of specific fungi by spraying, *Glomerella* and *Diaporthe* were controlled least, while *Sporonema* was effectively controlled by two or three applications. The failure to control rots in the Early Black variety by three applications of bordeaux on one bog in 1933 was probably due to the fact that the bog was reflooded early in June, prior to the first application.

**Pocket atlas of the diseases of grapevines**, O. APFEL and A. ZSCHOKKE (*Taschenatlas der Krankheiten des Weinstockes*. Berlin: Paul Parey, 1934, pp. [3]+25, pls. 24).—This handbook consists of 24 colored plates, each with accompanying descriptive notes.

**Factors concerned in the control of black rot of grape**, T. F. MANNS (*Peninsula Hort. Soc. [Del.] Trans.*, 49 (1935), pp. 55-57).—This contribution by the Delaware Experiment Station outlines briefly the results of demonstra-

tions and observations on black rot control during 1935. Cracking of the berries due to water pressure from excessive rains was severe, but it appeared to be somewhat checked by late diskings or cultivation. Control of the black rot requires a properly timed program with thorough spraying, and a fish oil spreader is recommended for the applications just before and after blooming.

**Second contribution to the study of court-noué of the vine** [trans. title], J. BRANAS and G. BERNON (*Ann. École Natl. Agr. Montpellier, n. ser., 24* (1936), No. 1, pp. 15-56, figs. 2).—It was found by these studies that at certain points in the annual growth cycle of the grapevine the content of tannin compounds in various organs (particularly the perennial ones) is higher in the court-noué than in the healthy vines. Whether these tannin substances play a direct or indirect causative role in court-noué or, more probably, are a host reaction to the disease are questions not yet to be answered definitely, but a study of the metabolic relations of the tannins in both normal and affected plants will undoubtedly aid in solving the problem.

**Third contribution to the study of court-noué of the vine** [trans. title], J. BRANAS and G. BERNON (*Rev. Vitic., 85* (1936), No. 2216, pp. 469-472).—Continuing this series, the authors found the leaves of affected vines to be richer in glucides than those of healthy vines. This difference was especially induced by the gradual increase in the content of reducing sugars. The same conditions prevailed in the perennial organs as in the leaves.

**Practical methods of disease control on avocado**, D. F. PALMER (*Calif. Dept. Agr. Bul., 25* (1936), No. 2, pp. 260-269, figs. 5).—Data are included for *Dothiorella*, tipburn, lime chlorosis, cankers, little leaf, sun blotch, and oak root fungus (*Armillaria mellea*).

**Zinc relation in mottle-leaf of citrus**, A. R. C. HAAS (*Bot. Gaz., 98* (1936), No. 1, pp. 65-86, figs. 7).—In this study by the California Citrus Experiment Station with both healthy and mottled Valencia leaves the zinc treatment increased the number of leaves that rooted and fewer leaves died than among the controls. Although the average fresh weights of mottled orange leaves were less than in healthy leaves, such weights of the root systems of mottled leaves were greater. Zinc treatment benefited the rooting of healthy lemon leaves but failed to improve that of mottled leaves. Mottled leaf cuttings rooted as well as, if not better than, the healthy ones.

The leaves of mottled Valencia leafy-twig cuttings had lower fresh weights than those of the healthy cuttings but produced heavier root systems, and zinc treatment of the mottled cuttings increased the weights of fresh roots per gram of fresh leaves. Zinc treatment retarded the root growth of lemon leafy-twig cuttings, but the untreated mottled cuttings produced a higher fresh weight of roots than the healthy ones.

The various parts of untreated, rooted, mottled Valencia leafy-twig cuttings contained more sucrose than corresponding parts of nonmottled cuttings, but zinc treatment lowered the sucrose content of leaves and roots at the end of the test. The dry matter of mottled, field-grown leaves contained slightly more reducing and total sugars than the healthy leaves. This increased sugar content aids in a rapid recovery once the limiting condition is removed. In sand or soil cultures, an excess of urea, urea-calcium nitrate mixtures, cyanamide, dicyanamide, or arsenic induced partial chlorosis. With urea, little leaf was induced. Rooted cuttings grew well in culture solutions when phosphate was supplied for a few days at intervals of several weeks and when aluminum was present during the absence of phosphate.

For the first time mottle-leaf was produced in Valencia leaves of rooted leafy-twig cuttings in culture solutions, but thus far only in the absence of zinc or with low zinc concentrations under continuous high light intensities.

When zinc concentrations in the solution were somewhat excessive, the addition of aluminum affected growth beneficially. Zinc, when not too high in concentration, induced a dark-green color in the leaves.

By coating the leaf surfaces on rooted Valencia leafy-twig cuttings grown in culture solution with a mixture of zinc, the toxic effect or its temporary growth-inhibiting or retarding effect could be noted. Such effects may partially account for the variations frequently observed in the rate of response of trees to zinc applications.

**Progress in zinc sulphate studies**, A. F. CAMP and W. REUTHER (*Citrus Indus.*, 17 (1936), No. 3, pp. 12, 14).—This contribution by the Florida Experiment Station is an address summarizing the authors' results in the use of zinc sulfate for the control of citrus mottle-leaf, with special reference to the time, amount, and character of the applications.

**Xyloporosis, the new disease, its causes, and prevention**, S. BAUMGAERT (*Hudar*, 9 (1936), No. 3, pp. 71-74, figs. 6).—The "new disease" of limes is said to be due to disturbances in the circulation of the descending sap following mechanical injury of the stock in budding. Possible contributory factors are also mentioned.

**Fungus diseases of feijoa** [trans. title], G. V. ARTEM'EV (ARTEMIEV) (*Sovet. Subtrop.* (*Soviet Subtrop.*), No. 7 (1935), pp. 61-63, figs. 5).—The pathogenic fungi described and briefly discussed include *Phyllosticta feijoicola*, *P. feijoa*, *Leptosphaeria feijoa*, *Mycosphaerella feijoa*, and *Phoma feijoa*, all new species.

**The pineapple root system as affected by the root-knot nematode**, G. H. GODFREY (*Phytopathology*, 26 (1936), No. 5, pp. 408-428, figs. 5).—The symptoms of root knot due to *Heterodera marioni* in pineapples are terminal and non-terminal galls in the main roots, brooming sometimes to several orders of branching, and very small rootlet galls. Large compound galls are not formed. Detailed symptoms change constantly owing to decay of old galls, development of new axillary roots, and the activities of other organisms. Soil infestation of at least 100 larvae within an inch of a root tip is necessary to produce a terminal gall on that root. General soil infestation of at least 172,800 larvae per cubic foot of soil is necessary to stop all the primary roots, and thus seriously to retard early growth. When the root system escapes this heavy, early infection, the plant can make a good start and may produce a fair crop of fruit. However, smaller scattered infections may gradually build up a large nematode population, resulting in abundant infection of new roots later in the life of the plant.

**The drying up of the young branches of almonds in relation to some fungi** [trans. title], A. CANONACO (*Riv. Patol. Veg.*, 26 (1936), No. 5-6, pp. 145-164, pl. 1, fig. 1).—The author reports his study of an almond tree blight shown to be due to *Phomopsis amygdalina* n. sp.

**Control practice for diseases and pests of ornamental plants**, H. PAPE (*Die Praxis der Bekämpfung von Krankheiten und Schädlingen der Zierpflanzen*. Berlin: Paul Parey, 1936, 2. ed., rev., pp. VIII+427, pls. 8, figs. 303).—In part 1 the author discusses the economic significance, causes, and methods of preventing and combating diseases and pests of ornamentals. In part 2, comprising the greater portion of the monograph, a section is devoted to the diseases and pests affecting many genera and species of ornamentals and a second and larger section to the diseases and pests of specific genera and species, arranged alphabetically according to host genera. The diseases include those due to fungi, bacteria, and higher plants, as well as those of nonparasitic origin, and the pests include insects and other noxious animals.

A bibliography of about five pages and an index complete the work.

**Ornamental flowering plants experimentally infected with curly top**, J. H. FREITAG and H. H. P. SEVERIN (*Hilgardia* [California Sta.], 10 (1936), No. 9, pp. 263-302, pls. 4, figs. 21).—In cooperation with the U. S. D. A. Bureau of Entomology and Plant Quarantine, experimental transmission of the curly top virus is reported for 92 species of ornamental flowering plants, including 33 families and 73 genera. The various types of symptoms produced are described. Fifteen species failed to develop symptoms under greenhouse conditions. The life cycle of the leafhopper vector, *Eutettix tenellus*, was completed on 65 species.

**Sources of disease-resistant vegetable and flower seeds, 1936**, R. J. HASKELL, V. R. BOSWELL, ET AL. (*U. S. Dept. Agr., Ext. Serv. and Bur. Plant Indus.*, 1936, pp. 41).—This is a list of seed companies offering specified standard resistant varieties for sale in 1936 in the United States.

**Injuries by the leaf spot disease of Cineraria** [trans. title], H. WASEWITZ (*Blumen u. Pflanzenbau vcr. Gartenwelt*, 40 (1936), No. 9, pp. 99, 100).—In this note on attacks of *Cineraria* by *Ascochyta cinerariae*, the author briefly describes the symptoms and course of the disease and gives suggestions on its control.

**The influence of different fertilizer treatments on the bactericidal and fungicidal action of aqueous extracts of Clematis recta** [trans. title], G. MADAUS and H. SCHINDLER (*Biol. Zentbl.*, 56 (1936), No. 3-4, pp. 167-173, fig. 1).—Aqueous extracts of *C. recta* variously fertilized (artificial fertilizer, leafmold, manure, and liquid manure) were tested for their effects on *Bacterium coli* [= *Escherichia coli*], *Aspergillus niger*, and *Oidium lactis*. The results indicated that the plants treated with the organic fertilizers were significantly more fungicidal and bactericidal than the controls or those treated with inorganic fertilizers.

**Passion vine diseases**, J. H. SIMMONDS (*Queensland Agr. Jour.*, 45 (1936), No. 4, pp. 322-330, figs. 8).—This is a general discussion of the diseases of passionflower [*Passiflora* spp.] and their control in Queensland.

**Privet and jasmine galls produced by a species of Phomopsis**, N. A. BROWN (*Phytopathology*, 26 (1936), No. 8, pp. 795, 797-799, fig. 1).—Galls observed on the common privet (*Ligustrum vulgare*) and on *Jasminum nudiflorum* in the southern United States were shown to be due to an apparently identical species of *Phomopsis*, since the two strains appeared similar and cross-inoculations were successful. Successful inoculations of the privet strain were also made on *L. amurense* and on the olive. Whether the fungus is a new species is as yet unknown.

**Cytosporina ludibunda on American elm**, J. C. CARTER (*Phytopathology*, 26 (1936), No. 8, pp. 805, 806).—The prevalence of *C. ludibunda* was observed on wilting American elms in Illinois during the summers of 1934 and 1935, fruiting of the fungus occurring in the cankerous tissue. Successful inoculations were made with pure cultures of the fungus on potted American elms.

**A second report on the status of the Dutch elm disease**, G. R. GAGE (*Jour. Tenn. Acad. Sci.*, 11 (1936), No. 2, p. 141).—The status of the disease in four eastern areas is noted up to November 15, 1935.

**Pseudolarix amabilis, a new host for Dasyscypha willkommii**, J. A. MILLER and K. F. ALDRICH (*Science*, 83 (1936), No. 2160, p. 499).—Typical cankers occurred on this host in Massachusetts.

**The bark canker of poplars** [trans. title], W. BAVENDAMM (*Tharandter Forstl. Jahrb.*, 87 (1936), No. 2, pp. 177-179, fig. 1).—This is a report of observations in Germany on a disease of young poplars—most severe on the more rapidly growing *Populus* spp.—due to *Dothichiza populea*, probably the pycnidial

form of *Oenangium populeum*. The disease is said to be very similar to a bark disease of oaks previously reported (E. S. R., 74, p. 805).

A new disease of Sitka spruce in Germany [trans. title], T. ROHDE (*Zitschr. Pflanzenkrank. u. Pflanzenschutz*, 46 (1936), No. 6, pp. 277-284, figs. 8).—The author describes and illustrates the symptoms of a new disease of Sitka spruce noted in two localities of the Province of Hannover, due to a new species of fungus, named by R. Kirschstein *Pezizula rohdeana*.

Effects on trees of an illuminating gas in the soil, C. G. DEUBER (*Plant Physiol.*, 11 (1936), No. 2, pp. 401-412).—When from 5 to 10 cu. ft. of a coke-oven type illuminating gas were applied to the roots of elm trees no visible effects followed, but from 32 to 864 cu. ft. induced a variety of symptoms, chief among which were chlorosis and defoliation in the early stages, in some cases followed by drying out of the apical parts of the stems. Roots were also injured, and epinasty of leaves followed gassing when the soil surface was sealed. The lower buds were stimulated into active growth on stems defoliated by gassing. Before the beginning of the second growing season, 2 of the 20 treated trees died. Trees with their roots exposed to from 5 to 10 cu. ft. of gas showed no injuries the second season, but those exposed to from 46.2 to 864 cu. ft. showed dried distal parts of some stems or branches, with new, healthy shoots developing below, and with very little injury to the roots. It is suggested that ethylene or constituents of the gas with a physiological action similar to that of ethylene would explain the injurious, lethal, and stimulative effects obtained.

Studies on the wood-rooting fungus, *Fomes pini*.—II, Cultural characteristics, C. E. OWENS (*Amer. Jour. Bot.*, 23 (1936), No. 4, pp. 235-254, pls. 6, fig. 1).—In this second contribution (E. S. R., 75, p. 654), an account is given of the cultural variations found among 80 isolates obtained from 6 genera and 19 species of coniferous trees. "The habit of growth of *F. pini* on *Abies grandis* and the cultural characters of isolates from this host species indicate that the variant of the fungus occurring on this host is distinct from that on species of *Pinus*, *Pseudotsuga*, *Tsuga*, *Picea*, and *Larix*, and from that on some other species of *Abies*. On account of lack of material from the European and New England species of *Abies* and *Picea* for critical study, no statement is ventured as to whether the form which the writer studied on *A. grandis* is identical with *F. pini* (Thore) Lloyd var. *abietis* Karst."

The influence of fungal decay on the properties of timber.—I, The effect of progressive decay by *Polyporus hispidus*, Fr., on the strength of English ash (*Fraxinus excelsior*, L.), K. ST. G. CARTWRIGHT, W. G. CAMPBELL, and F. H. ARMSTRONG (*Roy. Soc. [London], Proc., Ser. B*, 120 (1936), No. 816, pp. 76-95, figs. 9).—Parallel series of mechanical tests and chemical analyses indicated that the bending strength is affected immediately by fungus infection, but that the elasticity or stiffness is only slightly impaired in the early stages. The loss in crushing strength was small and gradual throughout the period of exposure to decay. Attention is called to the serious reduction in toughness of ash wood caused by *P. hispidus*, even during the early stages of attack when the decay is still undetectable.

The chemistry of the white rots of wood.—IV, The effect on wood substance of *Ustilina vulgaris* Tul., W. G. CAMPBELL and J. WIETELAK (*Biochem. Jour.*, 29 (1935), No. 6, pp. 1318-1321).—Continuing these studies (E. S. R., 71, p. 741), it was found that *U. vulgaris* induces in wood of linden (*Tilia vulgaris*) a type of decomposition characterized as white rot. Its chief nutrient is the carbohydrate part of the cell wall, but lignin is also decomposed to some extent. Its saprophytic action on beechwood is slow but chemically of

the same order as its parasitic action. The experimental data from decayed linden wood suggest that this fungus must be highly detrimental to the mechanical properties of the wood.

**Stimulated activity of natural enemies of nematodes, M. B. LINFORD** (*Science*, 85 (1937), No. 2196, pp. 123, 124).—In recent studies over 20 nematode-destroying species of fungi have been recognized in Hawaiian soils, some apparently identical with forms described by Drechsler (*E. S. R.*, 76, p. 650) and others elsewhere. Many were found to destroy larvae of the root knot nematode *Heterodera marioni*, although not to the extent of extermination. Laboratory and glasshouse experiments are reported whereby increased activity of these fungi was induced by the incorporation of fresh pineapple plant material into soils, accompanied within 3 weeks by striking reductions in larval populations. Similar reductions occurred in soil treated with applications of grass at the rate of 165 tons per acre-foot.

### ECONOMIC ZOOLOGY—ENTOMOLOGY

[**Work in economic zoology and helminthology by the Hawaii Station**] (*Hawaii Sta. Rpt. 1936*, pp. 12, 13, 14, 79–92, figs. 4).—Reporting for the year the work referred to includes poultry parasites, namely, the gizzard worm *Cheilosporira hamulosa* of chickens and turkeys, particularly the finding of new intermediate hosts in 14 different species of arthropods, and intermediate hosts of other parasites of chickens in Hawaii, including the spiral stomach worm *Dispharynx spiralis*, the globular stomach worm *Tetrameres americana*, the eye worm *Oxyuris mansonii*, and a tapeworm (*Hymenolepis exigua*) not previously reported from Hawaii, etc., and parasites of pigs and horses, all by J. E. Alicata; the liver fluke of cattle, *Fasciola gigantica*, including a survey which has shown it to be widespread in the Islands, slaughterhouse reports of beef cattle, methods used for its control, and field experiments now in progress, by L. E. Swanson; species of liver fluke found in Hawaii (*F. gigantica*), by Alicata and Swanson; life history of *F. hepatica* and silage as a possible means of killing liver fluke larvae encysted on grass, both by Alicata; and rodent control.

[**Work in economic zoology, entomology, and limnology by the Cornell Station**] ([*New York*] *Cornell Sta. Rpt. 1936*, pp. 88, 89, 100 107, 134).—The work of the year referred to (*E. S. R.*, 74, pp. 809, 811) included the nutritional requirements of trout, by C. M. McCay and A. V. Tunison; rations for mink, by L. A. Maynard and A. Z. Hodson; the alfalfa snout beetle *Brachyrhinus ligustici* L. and its control, by P. W. Claassen and C. E. Palm (*E. S. R.*, 76, p. 368); control of white grubs, by Palm; Dutch elm disease and the lesser European elm bark beetle, by P. A. Readio, D. L. Collins, D. S. Welch, K. G. Parker, and L. J. Tyler; insects attacking potatoes on Long Island, by G. F. MacLeod and W. Dickison; millipede and gnat injuries to potato tubers, by MacLeod and F. G. Butcher; wireworms and their injuries to potato tubers, by MacLeod and W. A. Rawlins; muck land potato spraying experiments, by MacLeod and H. Menusan, Jr.; onion thrips, by MacLeod and F. G. Maughan; insects attacking turf and ornamental plantings, by MacLeod and K. E. Maxwell; the onion maggot, sulfur as an insecticide, reactions of insects to radiant energy, and insect vectors of virus diseases, all by MacLeod; biology and control of the two common clothes moths, the columbine borer and the iris borer, and insects injurious to leaves and blossoms of plants in the flower garden, all by G. H. Griswold; fur resources of New York, by W. J. Hamilton, Jr.; weight-length relationship in fishes, by G. C. Embury and P. I. Tack; control of fish

hatchery diseases, by Embury, S. M. Brown, A. M. Phillips, and Tack; feeding experiments with young bass, by Embury; and artificial incubation of game birds' eggs, by A. L. Romanoff.

**A new technique for producing lesions of the encephalon cortex,** C. W. BROWN, F. M. HENRY, and E. E. GHISELLI (*Science*, 84 (1936), No. 2175, pp. 232, 233).—A description of a new technic employed at the University of California, accompanied by references to the literature.

**[The progress of research work with game in New York State]** (N. Y. State Conserv. Dept. Ann. Rpt., 25 (1935), pp. 319–357, fig. 1).—Research work for the year here reported (E. S. R., 74, p. 365) deals particularly with that relating to ruffed grouse, pheasant, and quail.

**Wild life research in Wisconsin,** A. LEOPOLD (*Wis. Acad. Sci., Arts, and Letters, Trans.*, 29 (1935), pp. 203–208).—A review of the progress of wildlife research in Wisconsin, presented with a list of 11 references to the literature.

**The fox in captivity** (Ontario Dept. Game and Fisheries Bul. 7 [1936], pp. [3]+161, pl. 1, figs. 35).—The several chapters of this handbook deal with the principles of ranch construction, feeds and feeding, practical breeding and selection of breeding stock, reproduction, preparation of pelts, parasitic diseases, diseases of the digestive tract, kidney diseases, distemper, and miscellaneous conditions.

**Seasonal food of skunks in New York,** W. J. HAMILTON, JR. (*Jour. Mammal.*, 17 (1936), No. 3, pp. 240–246).—Some 3,000 analyses of the visceral contents of skunks, more than one-half of which were the eastern form (*Mephitis nigra*), collected during a period of 9 yr. commencing in 1927 from trappers and fur buyers are reported upon, the details being given in three tables.

**Bioassays of rodenticides,** J. C. MUNCH, F. E. GARLOUGH, and J. C. WARD (*Jour. Amer. Pharm. Assoc.*, 25 (1936), No. 9, pp. 744–746).—In the discussion of this subject it is pointed out that bio-assays of rodenticides are necessary, since chemical assays often fail to indicate their physiological activities.

**Game birds of prairie, forest, and tundra,** A. WETMORE (*Natl. Geogr. Mag.*, 70 (1936), No. 4, pp. 461–500, pls. 16, figs. 5).—This is the fifteenth of the series of articles describing the bird families of the United States and Canada, illustrated by paintings by A. Brooks (E. S. R., 76, p. 63).

**The birds of Nevada,** J. M. LINSDALE (*Cooper Ornithol. Club, Pacific Coast Arijana*, No. 23 (1936), pp. 145, fig. 1).—A total of 338 species and subspecies of birds known to occur in Nevada, based upon the field work of 80 observers in the State from 1867 to 1935, inclusive, are recognized. In addition to the accounts of these forms, which take up the greater part of the work (pp. 27–133), the author considers the physiography of the State, presents an historical summary, refers to the field workers, and gives a list of localities, a check list of the birds, a hypothetical list, and a list of the literature cited.

**Winter food of the sharp-tailed grouse and pinnated grouse in Wisconsin,** F. J. W. SCHMIDT (*Wilson Bul.*, 48 (1936), No. 3, pp. 186–203, figs. 3).—This contribution deals with the winter food only, based upon observations (1) at winter feeding stations and grain food patches, (2) of migrant prairie chickens on their wintering grounds, (3) of grouse budding in trees, (4) made by back-tracking flushed grouse, (5) of artificial feeding of grouse in pens, and (6) of the crop contents of 19 grouse collected during the winter. The dietaries of the prairie sharp-tailed grouse (*Pedioecetes phasianellus campestris*) and the greater prairie chicken or pinnated grouse (*Tympanuchus cupido americanus*) overlap but are nevertheless essentially different, the former being a northern bird that extends into Wisconsin from the northwest while the latter is a more southern bird extending into Wisconsin from the south. The winter food habits

of the two species are discussed separately, from the standpoint of grouse management, with special reference to the question of how much, if any, grain and cultivated weed seed is necessary, and at what seasons. The palatability sequence of winter foods for the prairie sharp-tailed grouse, northern sharp-tailed grouse, pinnated grouse, and the ruffed grouse is summarized in a table.

**Food habits of marsh hawks in the glaciated prairie region of north-central United States**, P. L. ERRINGTON and W. J. BRECKENRIDGE (*Amer. Midland Nat.*, 17 (1936), No. 5, pp. 831-848).—The results of studies by the Iowa Experiment Station of the food habits of the marsh hawk (*Circus hudsonius* (L.)) in the glaciated prairie agricultural region during the summers of 1933, 1934, and 1935 are presented in detail in four tables. The food habits of the marsh hawk in late summer, fall, winter, and spring, its adaptations for securing prey, and its pressure upon prey populations are dealt with. A thousand individuals of vertebrate prey taken by the marsh hawks hunting in Iowa, Minnesota, and Wisconsin were identified.

"The marsh hawk, in common with most other predators, seems to feed chiefly upon whatever it finds conveniently available as food, whether that food be carrion (of fresher grades) or captured prey. The carrion eaten is represented in large measure by carcasses of animals killed along highways by motor traffic; the prey, by young rabbits, mice, the smaller ground squirrels, passerine birds, and young or crippled individuals of larger species, including ring-necked pheasants.

"From the findings of intensive studies of vertebrate populations, it is becoming increasingly apparent that the role of predation in determining population levels of prey species may be of far less consequence on the whole than has been previously believed. A great deal of the pressure of predators—that of marsh hawks included—seems to be centered upon those proportions of the prey populations that tend to exceed the capacities for accommodation of their respective habitats."

A list is given of 29 references to the literature.

**The ring-necked pheasant as a nesting parasite of other game birds**, L. J. BENNETT (*Iowa State Col. Jour. Sci.*, 10 (1936), No. 4, pp. 373-375).—In a study in 1934 by the U. S. D. A. Bureau of Biological Survey and the Iowa Experiment Station cooperating, approximately 4.7 percent of the puddle duck nests in the prairie area of Iowa were found parasitized by the ring-necked pheasant. The pheasant eggs deposited in duck nests apparently reduced the potential number of duck eggs. A small percentage of pheasant eggs deposited in duck nests hatched. There is no apparent strife between nesting ducks and nesting pheasants. A small percentage of king rail nests, Virginia rail nests, and European partridge nests is parasitized by pheasants.

**The waterfowl situation**, F. C. LINCOLN (*Bul. N. Y. Zool. Soc.*, 39 (1936), No. 5, pp. 184-193, figs. 10).—A discussion of the waterfowl situation, contributed from the U. S. D. A. Bureau of Biological Survey.

**The Pacific rattlesnake**, C. T. VORHIES (*Calif. State Dept. Pub. Health Weekly Bul.*, 15 (1936), Nos. 21, pp. 81-83; 22, pp. 86, 87).—This is a practical account of *Crotalus confluentus oreganus*.

**The amphipod *Orchestia platensis* an intermediate host for *Hymenolepis exigua*, a tapeworm of chickens in Hawaii**, J. E. ALICATA (*Jour. Parasitol.*, 22 (1936), No. 5, pp. 515, 516, fig. 1).—During the course of a study of several invertebrates collected from various poultry farms near Honolulu the author discovered that the amphipod *O. platensis* was frequently parasitized by many cysticeroids. Upon infestation of day-old chicks that were killed at 3 weeks of age, these proved to be *H. exigua*, a tapeworm of chickens in Hawaii.

**Earthworms as transmitters of *Capillaria annulata*, the "crop-worm"** of chickens, E. E. WEHR (*North Amer. Vet.*, 17 (1936), No. 8, pp. 18-20, fig. 1).—It is concluded from natural and experimental ingestion of infested earthworms by chickens and the identification of larvae that *C. annulata* utilizes earthworms (*Helodrilus foetidus* and *H. caliginosus*) as intermediate hosts. It is pointed out that this unexpected finding clearly indicates the necessity for revising current ideas as to the life histories of nematodes of the suborder Trichurata.

**The senses involved in the courtship of some vagabond spiders**, B. J. KASTON (*Ent. Amer., n. ser.*, 16 (1936), No. 2, pp. 97-166, figs. 23).—A contribution from the Connecticut [New Haven] Experiment Station.

**Insect metabolism at temperatures below zero**, I. V. KOŽANČIKOV (KOZHANTSCHIKOV) (*Compt. Rend. (Dok.) Acad. Sci. U. R. S. S., n. ser.*, 3 (1935), No. 8, pp. 373-376, fig. 1).—The results of work with the European corn borer and the beet webworm are reported upon.

**The occurrence of insects at some height in the air, especially on the roofs of high buildings**, E. P. FELT and K. F. CHAMBERLAIN (*N. Y. State Mus. Circ.* 17 (1935), pp. 70, figs. 4).—An annotated list is given of the insects and spiders collected during the season of 1927 on the roof of a high building in each of several localities, including Albany, New York City, and Mount Vernon, and in the observation rooms of the fire towers at Athol (Warren Co.) and Stephentown (Rensselaer Co.), N. Y. A description is given of the collecting sites and a summary and discussion of the results of the work in which approximately 1,000 different species representing a wide variety of groups were captured. Among these were some 25 species previously unknown from New York State, 1 species (*Oxythrips ajugae* Uzel) not previously recognized in North America, and representatives of 2 new genera.

**Aberrant feeding behavior among insects and its bearing on the development of specialized food habits**, C. T. BRUES (*Quart. Rev. Biol.*, 11 (1936), No. 3, pp. 305-319, fig. 1).—This contribution is accompanied by a four-page classified list of references to the literature.

[Contributions on economic insects and their control] (*Peninsula Hort. Soc. [Del.] Trans.*, 48 (1934), pp. 12-19, 30-44, figs. 6; 49 (1935), pp. 31-39, 61-64, 86-102, fig. 1).—Contributions relating to fruit insects, particularly the codling moth, and their control presented at the December 1934 meeting of the Peninsula Horticultural Society (E. S. R., 71, p. 666) include the following: Results of Experiments With Non-arsenicals for Codling Moth Control, by W. S. Hough (pp. 12-14), contributed from the Virginia Experiment Station; Codling Moth Problem on the Eastern Shore, by E. N. Cory (pp. 15-19); and An Examination of the Factors Determining Spraying and Other Recommendations for Control of the More Important Insect Pests of Apple, Peach, and Grape During the Five-Year Period 1930-1934, by L. A. Stearns (pp. 30-44), contributed from the Delaware Experiment Station.

Those presented at the December 1935 meeting include Present Status of the Rosy Apple Aphid and Its Control in Virginia Orchards, by W. S. Hough (pp. 31-34), contributed from the Virginia Experiment Station; Codling Moth Situation, by E. N. Cory (pp. 35, 36); Experiments on the Control of the Mexican Bean Beetle, by G. S. Langford and S. L. Crosthwait (pp. 37-39); Corn Borers, by L. P. Ditman (pp. 61-64), contributed from the Maryland Experiment Station; and Control of the Lesser Peach Borer, by H. G. Guy (pp. 86-88), Notes on the Ragweed Borer *Epiblema strenuana* Walk. and Its Parasites, by P. L. Rice (pp. 89-94), and Results of Experimental Spraying During 1935 for Control of Codling Moth, by L. A. Stearns, P. L. Rice, and H. G. Guy (pp. 95-102), all contributed from the Delaware Experiment Station.

**[Report of work in entomology by the West Virginia Station]** (*West Virginia Sta. Bul.* 278 (1936), pp. 28-30).—The work of the biennium 1935-36 briefly referred to (E. S. R., 72, p. 654) includes the use of insecticides and bands for control of the codling moth, search for more convenient treatments for control of the pistol casebearer, and progress of a study of the relation of temperature to insect development.

**[Contributions on economic insects and their control]** (*Ohio Veg. Growers Assoc. Proc.*, 20 (1935), pp. 21-25, 27-34, 130, 132, 134, 136).—Contributions here presented (E. S. R., 73, p. 505) include the following: Derris for the Control of Certain Vegetable Insects, by N. F. Howard, H. C. Mason, and R. H. Davidson (pp. 21-25); and The Tomato Fruit Worm [Corn Earworm] Problem, by J. S. Houser (pp. 27-34), and Controlling Insects on Muck Crops, by J. P. Slesman (pp. 130, 132, 134, 136), both contributed from the Ohio Experiment Station.

**[Report of work in entomology]** (*California Sta. [Bien.] Rpt.* 1935-36, pp. 84-90).—The work of the biennium 1935-36 referred to (E. S. R., 72, p. 654) includes control of insect pests by parasites, improvements in tank-mix oil sprays for citrus (E. S. R., 75, p. 666), cyanide fumigation of citrus and avocados, citrus red mite control by Selocide (E. S. R., 75, p. 234) and by dinitro-*o*-cyclohexylphenol (E. S. R., 75, p. 224), the codling moth on walnuts (E. S. R., 74, p. 522), codling moth control program for pears, a tomato insect survey, spray residues from Selocide, light traps (E. S. R., 73, p. 509), and bean and pear thrips control.

**Report on the entomological section for the year ending March 31st, 1936**, R. W. E. TUCKER (*Agr. Jour. [Barbados]*, 5 (1936), No. 2, pp. 67-75, fig. 1).—This report (E. S. R., 74, p. 513) relates particularly to the rearing and release of *Lixophaga diatraca* parasites of the sugarcane borer, the details of a survey of which are given in a table.

**Recent entomological investigations, [I], II**, F. A. SQUIRE (*Agr. Jour. Brit. Guiana*, 6 (1935), No. 2-3, pp. 84-90, figs. 2; 7 (1936), No. 1, pp. 21-26, pls. 2).—The first part of this contribution reports upon the hardness of rice made in the course of an investigation of the rice weevil and gives a list of additions to the entomological collection; part 2 presents an account of the plantain and banana beetle *Colaspis hypochlora* Lefev. (pp. 21-24), followed by a brief contribution on field studies of the parasitism of the egg of the coconut caterpillar *Brassolis sophorae* L. by *Telenomus nigrocoaxalis* Ashm. and of the pupa by *Chalcis annulata* and *Spilochalcis brassolis*.

**[Work in entomology at the Rothamsted Experimental Station]** (*Rothamsted Expt. Sta., Harpenden, Rpt.*, 1935, pp. 58-66, 80-82).—The work of the year, including that with insecticides and beekeeping, together with a list of the contributions on bees published by the station from 1926 to 1935, inclusive, and the occurrence of insect pests at Rothamsted and Woburn in 1935 by A. C. Evans, are reported upon.

**Injurious insects of Cyprus**, H. M. MORRIS (*Cyprus Agr. Jour.*, 31 (1936), Nos. 1, pp. 9-11; 2, pp. 58-64; 3, pp. 83-93; 4, pp. 125-132).—A brief report on the insects of economic importance in Cyprus.

**Some insect pests recorded from the mandated Territory of New Guinea**, J. L. FROGGATT (*New Guinea Agr. Gaz.*, 2 (1936), No. 1, pp. 15-18).—Insect pests recorded from the Territory of New Guinea are listed according to hosts attacked.

**The control of injurious insects**, E. RONCONI (*La lotta contro insetti dannosi. Varese: Tipog. Arc. Addolorata*, 1935, pp. 263+[10], pls. 43, figs. 35).—Following a general account, this contribution deals with some of the more important insects met with in the Province of Varese, particularly cockchafers (*Melolontha* spp.) and the pine processionary *Thaumetopoea pityocampa*.

**Relative toxicity of pyrethrins I and II to insects, A. HARTZELL and F. WILCOXON** (*Contrib. Boyce Thompson Inst.*, 8 (1936), No. 3, pp. 183-188, fig. 1).—The possibility that discrepancies in the findings of various investigators as to the relative toxicity of pyrethrins I and II might be due either to different susceptibilities in the insects used or differences in the physical state of the pyrethrins at the moment of application led to the experiments here reported.

"A partial separation of pyrethrins I and II was effected by multiple extraction, using as solvents petroleum ether and aqueous acetic acid. Extracts were obtained in which the ratio of I to II varied from 4 to 0.047 according to the Seil method of analysis. The comparative toxicity of pyrethrum extracts varying in ratio of pyrethrins I and II was determined on *Aphis rumicis*, using acetone and a miscible oil as solvents for the pyrethrins with water. When extracts high in pyrethrin I were compared with extracts high in pyrethrin II, using acetone as a solvent, the pyrethrin I extracts were considerably more toxic than extracts high in pyrethrin II. When a miscible oil such as Penetrol was used as a solvent the difference in toxicity tended to disappear. When similar extracts were tested on houseflies (*Musca domestica*), by means of both the Peet-Grady method and a modified Nelson method, the differences obtained in the toxicity of extracts high in pyrethrin I and extracts high in pyrethrin II were not statistically significant. The results indicate that the physical condition of the pyrethrins at the time of application is a determining factor in the relative toxicity at least so far as *A. rumicis* and *M. domestica* are concerned. The relative toxicity of pyrethrins I and II depends almost entirely upon the method of application used."

**Investigations on the insect and allied pests of cultivated mushrooms, IV, V, M. D. AUSTIN and S. G. JARY** (*Jour. Southeast. Agr. Col., Wye, Kent, Va.* 36 (1935), pp. 103-110).—The fourth part of this contribution (E. S. R., 72, p. 502) considers the natural fauna of stable manure used in the preparation of mushroom beds (pp. 103-106), and the fifth part reports experiments on the control of flies and mites (pp. 107-110). Sprays containing nicotine (98 percent) at a dilution of 1:1,600 were not effective in killing eggs of *Sciara fenestralis*, and the addition of sulfonated lorol, 1:4,000, did not increase the efficiency of the spray. "Larvae of *S. fenestralis* were somewhat affected by nicotine sprays, but under the most favorable experimental conditions a mortality of only 60 percent was obtained. Under commercial conditions a much lower mortality would be expected. In mushroom houses nicotine sprays are only effective against adult flies, and spraying should therefore be done frequently as a matter of routine to prevent a large population of adult flies accumulating. Solutions of common salt at a dilution of 1:160 showed no toxicity toward larvae of *S. fenestralis*. Two wetting agents, sulfonated lorol and sodium  $\gamma$  sulfonate, at dilutions of 1:2,000, were harmless when applied as sprays on growing mushrooms. A proprietary oil emulsion when carefully mixed and lightly sprayed on growing mushrooms checked the injury caused by tyroglyphid mites. A light application when the temperature of the liquid was 104° F. produced no injury to mushrooms. Warm water applied at a temperature of 110° also caused no injury to mushrooms."

**Control of tobacco insects in Tennessee, S. MARCOVITCH and W. W. STANLEY** (*Tennessee Sta. Bul.* 160 (1937), pp. 14, figs. 17).—A practical summary is given of control measures under Tennessee conditions. Of the insecticides tested by the station, the fluorine compounds are said to have come nearer to meeting the requirements than any of the materials that have been commonly used.

[Contributions on orchard insect pests] (*Ind. Hort. Soc. Trans.*, 1934, pp. 32-49, 62-82; 1935, pp. 29-67, 139-142, fig. 1).—Contributions presented at the

seventy-fourth annual meeting of the Indiana Horticultural Society (E. S. R., 72, p. 216), held in January 1935, related particularly to the codling moth and its control, including the following: Pruning As an Aid in Codling Moth Control, by M. McCown (pp. 32, 33); The Value of Supplementary Measures in the Codling Moth Control Program, by L. F. Steiner, A. J. Ackerman, and D. W. Hamilton (pp. 34-40); Present Status of Chemically Treated Bands for Use in Codling Moth Control, by G. E. Marshall (pp. 41-43), Residue Loads Resulting From First and Second Brood Sprays, by C. L. Burkholder (pp. 45-47), and 1934 Codling Moth Spray Tests, by G. E. Marshall (pp. 62-65), all contributed from the Indiana Experiment Station; Insecticide Tests to Control the Codling Moth at the Vincennes, Indiana, Laboratory During 1934, by L. F. Steiner, R. F. Sazama, and J. E. Fahey (pp. 66-71); and The Significance of Supplementing Controls in Combating the Codling Moth, by J. J. Davis (pp. 72-82), contributed from the Indiana Experiment Station.

The contributions presented at the meeting held in January 1936 include the following: Notes on Codling Moth Control in New Jersey, by B. F. Driggers (pp. 29-36), contributed from the New Jersey Experiment Stations; The Relative Efficiency of Certain Lead Arsenate Spray Treatments, by L. F. Steiner, R. F. Sazama, J. E. Fahey, and H. W. Itusk (pp. 38-43); and Trends in Orchard Insect Problems, by J. J. Davis (pp. 53-56), The Results of 1935 Codling Moth Control Experiments, by G. E. Marshall (pp. 56-64), and The Cost of Controlling Apple Insects and Diseases, With Special Reference to the Codling Moth, by M. S. Troth and G. E. Marshall (pp. 139-142) (E. S. R., 73, p. 809), all from the Indiana Experiment Station.

[Contributions on orchard fruit insects and their control] (*Conn. Pomol. Soc. Proc.*, 44 (1934), pp. 24-26, 26, 27, 82-88, 89-93, 94-106).—Among the contributions presented (E. S. R., 72, p. 215) at the 1934 meeting of the Connecticut Pomological Society are the following: The Oriental Peach [Fruit] Moth Parasite Situation (pp. 24-26) and Control of Orchard Pests (pp. 82-88), both by P. Garman, contributed from the Connecticut [New Haven] Experiment Station; and The Fruit Tree Leafroller, by P. J. Chapman (pp. 89-93), and Apple Pest Control With Special Reference to Tar Oil Sprays, by F. Z. Hartzell (pp. 94-105), both contributed from the New York State Experiment Station. A brief report of the parasite distribution committee of the society for 1934, by H. M. Rogers et al., is also presented (pp. 26, 27).

The proceedings for the 1935 meeting have been noted (E. S. R., 76, p. 64).

Dormant oil sprays for apple pests, F. Z. HARTZELL (*Farm Res. [New York State Sta.]*, 3 (1937), No. 2, p. 9).—This contribution, based upon work noted above and previously (E. S. R., 75, pp. 375, 665), relates to tests of coal tar oil, coal tar oil with lubricating oil, and a new "DN" oil spray in an effort to control the rosy apple aphid, eye-spotted budmoth, and certain scale insects with one application.

[Control work with the white pine weevil and the gypsy moth in New York State] (*N. Y. State Conserv. Dept. Ann. Rpt.*, 25 (1935), pp. 85, 123-130, fig. 1).—Reference is made to the progress of control work with the white pine weevil (p. 85) and the gypsy moth (pp. 123-128, 129, 130).

The biology of *Pseudosinella violenta* (Folsom), with some effects of temperature and humidity on its life stages (Collembola: Entomobryidae), R. DAVIS and H. M. HARRIS (*Iowa State Col. Jour. Sci.*, 10 (1936), No. 4, pp. 421-428, pl. 1, figs. 6).—In reporting upon stages of the biology of *P. violenta*, one of the commonest springtails met with in Iowa, a description is given of a special technic devised for handling small soft-bodied insects.

Fighting grasshoppers on Illinois farms, J. H. BIGGER, W. P. FLINT, and M. D. FARRAR (*Illinois Sta. Circ.* 466 (1937), pp. 11, figs. 4).—A practical contri-

bution on grasshoppers of Illinois, in which State three, namely, the differential grasshopper, the lesser migratory locust *Melanoplus mexicanus* Sauss. or *M. atlantis* Riley, and the red-legged grasshopper, are responsible for nearly all the damage, together with means for their control.

**Research on termites in the United States**, T. E. SNYDER (*Amer. Wood-Preservers' Assoc. Proc.*, 32 (1936), pp. 302-309, figs. 4).—This contribution was presented at the annual meeting of the American Wood-Preservers' Association held in Memphis, Tenn., in January 1936.

**Report on certain dusts tested against citrus thrips on oranges**, E. A. MCGREGOR (*Calif. Citrogr.*, 21 (1936), No. 11, p. 436).—In the experimental application of dusts for control of the citrus thrips in California in 1934 and 1935, barium fluosilicate without sulfur was of little value, but when combined with 70 percent of sulfur the mixture gave a marked reduction of thrips damage. "Powdered derris and talc in 2 orchards gave indicated reductions of thrips damage amounting respectively to 45 and 84 percent. Such results are not promising. Pyrethrum and talc gave an indicated reduction of thrips injury amounting to 54 percent, which again is unsatisfactory. A dust containing 0.19 percent of pyrethrins and 44.1 percent sulfur resulted in 95 percent reduction in thrips damage. This high protection was doubtless due in large part to the sulfur. A dust combining rotenone 0.5 percent (in the form of derris dust) and sulfur dust 50 percent reduced thrips damage to the extent of 96 percent. Again the effectiveness was attributable in large measure to the sulfur in the mixture.

"Six different dusts containing zinc compounds equivalent to 4.25 to 17 percent zinc were applied in 1934 and 1935 in 11 orchard tests. The sulfur content of these dusts ranged from 27 to 84 percent. The reduction in thrips damage, following the use of these zinc-containing dusts, ranged from 78 to 100 percent. The average amount of thrips-damaged fruit in the series of plats treated with the zinc-sulfur dusts was only 4.8 percent. The foregoing data indicate that the addition of zinc compounds to the sulfur dusts does not noticeably lessen their effectiveness for control of the thrips."

See also a previous note (E. S. R., 72, p. 219).

**Our knowledge of California Thysanoptera previous to 1900**, S. F. BAILEY (*Pan-Pacific Ent.*, 12 (1936), No. 3, pp. 97-103).—This is a discussion of the early knowledge of the Thysanoptera in California, presented with a list of 10 references to the literature.

**On some Thysanoptera collected in France**, R. S. BAGNALL and O. JOHN (*Ann. Soc. Ent. France*, 104 (1935), No. 3-4, pp. 307-327).—An annotated catalog of 209 forms of Thysanoptera collected by the authors in France.

**The insecticidal action of acid lead arsenate on the larvae of the Japanese beetle in different types of soil**, W. E. FLEMING, F. E. BAKER, and L. KOBLITSKY (*Jour. Agr. Res. [U. S.]*, 53 (1936), No. 10, pp. 771-779).—In continuation of previous work (E. S. R., 75, p. 523), the authors report upon a study of the effectiveness of acid lead arsenate against larvae of the Japanese beetle in 15 types of New Jersey soil. The coefficient of insecticidal action ranged from 0.3 in Colts Neck loam to 2.18 in Lakewood sand. The difference in the action of acid lead arsenate appeared to be associated with some intrinsic property of the soils. "There was no correlation between the coefficient of insecticidal effectiveness and the total nitrogen, phosphates, potassium, calcium, magnesium, and carbon in the soils. The water-soluble constituents accounted for 77 percent of the variance in the insecticidal action. The concentrations of water-soluble phosphates, calcium, and magnesium appear to be the most important factors influencing the effectiveness of acid lead arsenate. The greater the concentrations of soluble phosphates and calcium in the soil when

acid lead arsenate is applied, the more effective it is, and the greater the concentration of soluble magnesium the less effective it is. The influence of soluble chlorides, manganese, nitrates, ammonia, and potassium in the soil on insecticidal action is of minor importance. Although the pH is a minor factor, the nature of the radicals producing the acidity or alkalinity being more important, it is apparent the acid lead arsenate is generally more effective in acid than in alkaline soils.

**An annotated list of the Lepturini of Oregon**, M. F. CANOVA (*Pan-Pacific Ent.*, 12 (1936), No. 3, pp. 126-132).—A systematic list with locality records of members of the cerambycid tribe Lepturini in Oregon.

**The elaterid beetles of the Philippine Islands**, R. H. VAN ZWALUWENBURG (*Philippine Jour. Sci.*, 59 (1936), No. 3, pp. 393-432).—In this contribution from the Hawaiian Sugar Planters' Experiment Station, the author lists some 204 species and 11 varieties of elaterid beetles occurring in the Philippines and gives locality records of their occurrence. Of the forms listed one species is described as new.

**The sisal weevil**, W. V. HARRIS (*East African Agr. Jour.*, 2 (1936), No. 2, pp. 114-126, figs. 9).—An account is given of *Scyphophorus acupunctatus* Gyll., a weevil which attacks young sisal plants, weak plants, and plants which have flowered, breeding particularly in the plant base. This pest of sisal in the Province of Tanga, Tanganyika, where it was apparently introduced with its host plant from its original home in Central America, requires from 50 to 95 days for the completion of its life cycle. Factors influencing the number of beetles present are discussed and control measures suggested.

**Observations on some Hemiptera attacking the cotton plant** [trans. title], J. V. LEROY (*Inst. Natl. Etude Agron. Congo Belge Pubs.*, Sér. Sci., No. 10 (1936), pp. 20, pls. 24).—Three hemipterous enemies of cotton in the Belgian Congo, together with their injury, are described and illustrated by colored and other plates, namely, *Lygus vosseleri* Popp, *Empoasca facialis* Jac., and *Helopeltis bergrothi* Reut.

**A new pentatomid enemy of rice in Rio Grande do Sul** [trans. title], A. DE COSTA LIMA (*Campo [Rio de Janeiro]*, 6 (1935), No. 10, p. 16, fig. 1).—Under the name *Ogmocoris reinigeri* n. sp. a description is given of a pentatomid enemy of rice in Porto Alegre.

**Distributional and synonymical notes on the beet leafhopper (*Eutettix tenellus* (Baker))**, P. W. OMAN (*Ent. Soc. Wash. Proc.*, 38 (1936), No. 7, pp. 164, 165).—Records of the distribution of the beet leafhopper indicate that it not only occurs in most of the western half of the United States but also in western Canada, western Mexico as far south as Guasave, Sinaloa, and in Florida. Specimens collected indicate that it may occur in Jamaica, in Puerto Rico, and also in Palestine in one of its forms.

**Studies on the incubation of the chinch bug egg**, M. J. JANES and A. HAGER (*Iowa State Col. Jour. Sci.*, 10 (1936), No. 4, pp. 395-402, figs. 3).—In observations at the Iowa Experiment Station, eggs of the chinch bug hatched in approximately 30 days at 19.5° C., 15 days at 24.5°, 10 days at 29.5°, and 7 days at 34.5°. Temperature seemed not to affect appreciably the percentage of hatch. In each case there was considerable spread in the time of hatching of a given lot of eggs subjected to the same conditions. Relative humidity, although apparently influencing the length of the incubation period in some cases to a slight extent, has its greatest effect on the percentage of hatch. The most favorable relative humidity at the higher temperatures was 80 percent. In one case 98 eggs hatched out of a lot of 100. Chinch bug eggs hatched after submergence in water for considerable periods of time; a number of eggs hatched after 15 days of submergence at 24.5°, but at higher temperatures

the eggs were less resistant to submergence. An increase in the incubation period occurred in fairly direct proportion to the period of submergence. A number of eggs were hatched after being submerged continuously for 23 hr. out of each 24 during the period of incubation.

**Studies on temperature and moisture as factors influencing winter mortality in adult chinch bugs,** G. C. DECKER and F. ANDRE (*Iowa State Col. Jour. Sci.*, 10 (1936), No. 4, pp. 403-420, figs. 8).—Chinch bugs collected by the Iowa Experiment Station from different sources varied in their resistance to low temperature exposures. "Bugs secured from the same locality at various times during the winter showed considerable variation in susceptibility to cold. When bugs were exposed for a long period at a constant temperature of 12.2° or -17.7° C., the percentage of mortality increased rapidly for about the first 10 hr. and after that the increase was less rapid. Precooling at sublethal temperatures increased the bugs' resistance to temperatures between -7° and -15°, but the mortality resulting from exposures to lower temperatures was not significantly different from that obtained by instant exposures. When the temperatures were lowered by steps a definite increase in resistance to fairly low temperatures (-7° to -12°) was noted, but this effect was gradually overcome as the exposure was prolonged. Dehydration produced by brief exposures at low relative humidities increased the resistance of the bugs. Chinch bugs which drank water were less resistant to low temperatures than those which did not. At 0° bugs held at high relative humidities lived longer and lost less weight than bugs held at low relative humidities. Chinch bugs submerged in water at 0.0° showed a 60 percent mortality after a 22-day period. Freezing chinch bugs in solid ice proved to be fatal in most instances."

**Control measures for mealy bugs on citrus,** J. R. WATSON (*Citrus Indus.*, 17 (1936), No. 7, pp. 15, 18).—A contribution from the Florida Experiment Station.

**Studies on the resistance and immunity of apples to the woolly aphis,** *Eriosoma lanigerum* (Hausm.), M. B. CRANE, R. M. GREENSLAIE, A. M. MASSEE, and H. M. TYDEMAN (*Jour. Pomol. and Hort. Sci.*, 14 (1936), No. 2, pp. 137-163, pls. 4).—An outline is given of the life cycle of the woolly apple aphid, and the hereditary behavior of the apple with respect to immunity to its attack is described. A description is also given of the entomological technic used in testing for resistance and immunity and of preliminary physiological investigations on the underlying causes. "It is tentatively concluded that the immunity to attack is determined by and dependent upon a certain balance of genetic factors, and that it is governed by a number of genes the action of which is in part complementary and in part cumulative."

**Toxicity of selenium-containing plants to aphids,** A. M. HURD-KARRER and F. W. POOS (*Science*, 84 (1936), No. 2176, p. 252).—Experiments have shown that the apple grain aphid is sensitive to concentrations of selenium in wheat plants. Aphids placed on 2-month-old plants supplied with concentrations of selenium greater than 3 p. p. m. all died within a few days, while those with lower concentrations lived for as long as a week, although without reproducing actively. Similar results were observed with the common red spider. The plants were stunted by concentrations greater than 3 p. p. m. of selenium. Comparatively few aphids survived on 1-month-old plants grown with but 1 p. p. m. of selenium, although some reproduction did take place. For some reason more of the aphids persisted on rye plants than on wheat, oats, and barley grown in soil treated with sodium selenate at the rate of 10 p. p. m. of selenium, although the number was greatly reduced.

The insect vector for the natural transmission of *Eperythrozoon coccoides* in mice, C. P. ELLIOT (*Science*, 84 (1936), No. 2183, p. 397).—The importance of a latent blood infection by *E. coccoides* in white mice used for experimental purposes which (like *Bartonella muris*) is activated by splenectomy is considered. Certain changes in the blood picture and in the size and histology of the spleen for which it is responsible may be sufficiently great at times to be significant in exact studies on the relation of the spleen to disease and resistance.

Transmission experiments with mites and lice have shown the mouse louse *Polyptrax serrata* to be the vector. In each of 11 experiments adults and nymphs transmitted *E. coccoides* from the infected to the uninfected host upon which it fed. In 2 other trials in which the adult lice were kept away from the host for several hours, transmission failed to take place. The nymphs from the same host, starved for the same length of time, were capable of transmitting *Eperythrozoon*. These results suggest that the strong digestive fluids of the adult louse destroy the organism, while the less active alimentary juices of the nymph permit longer survival.

Progress of cabbage worm investigations at the Ohio Agricultural Experiment Station, H. L. GUI (*Ohio Veg. Growers Assoc. Proc.*, 21 (1936), pp. 33-40).—Further work by the Ohio Experiment Station with the cabbageworm (*E. S. R.*, 73, p. 505), the details of which are here presented, has led to the following recommendations:

"For cabbage a dust consisting of 1 part of paris green, 1 part of hydrated lime, and 11.5 parts of a suitable diluent or a spray consisting of 2 lb. of paris green in 50 gal. of water should be used, but no applications of either material should be made less than 2 weeks before harvest. Any of the dust diluents on the market may be used, although flour has given the best results. Lime or gypsum should not be used in combination with fluorine insecticides.

"A spreader should be used in all sprays. Fish oil, glue, soap, and sulfated alcohol have been used with equal effectiveness. Sprays should be applied under a pressure of at least 200 lb. per square inch. Dust applications are preferred to sprays unless the latter are properly applied. Dust and spray applications should be made at approximately 10-day intervals.

"When it is necessary to apply treatment to cabbage less than 2 weeks before harvest or to cauliflower, broccoli, brussels sprouts, kale, and rape at any time, the use of derris powder is recommended. When used as a dust, derris powder should be diluted to a rotenone content of 0.5 percent, and, when used as a spray, each 50-gal. lot of spray should contain 0.05 lb. of rotenone."

The gipsy moth (*Porthetria dispar* L.) in the Crimean forests, V. П. ПАКХОМЕНКО (*Neparnii shovkopriud* [*Porthetria dispar* L.] u lisakh Krimu. *Kiev: Ukrain. Akad. Nauk, Inst. Zool. ta Biol.*, 1935, pp. 118, figs. 24; *Eng. abs.*, pp. 115-117).—The findings of the Crimean forest entomological expeditions of 1932 and 1933, in which the author participated, are reported upon. Data from the literature and the results of the Crimean forest entomological investigations of 1930 and 1931 are included.

"Dynamite" sprays, R. L. WEBSTER (*Better Fruit*, 31 (1936), No. [3], pp. 3, 4, fig. 1).—This is an account of control work with the codling moth, a report of which by Marshall and Groves has been noted (*E. S. R.*, 76, p. 72).

A contribution to the study of *Coleophora* attacking fruit trees [trans. title], J. SUIRE (*Ann. École Natl. Agr. Montpellier, n. ser.*, 24 (1936), No. 2, pp. 137-158, pls. 2).—This contribution relates particularly to *C. hemerobiella* Scop., its morphology, biology, parasites, and control measures, presented with a list of 31 references to the literature.

**The corn earworm.**—Third report, L. P. DITMAN and E. N. COBY (*Maryland Sta. Bul.* 399 (1936), pp. 77-90, figs. 3).—In this third report of studies of the corn earworm (E. S. R., 66, p. 55; 70, p. 66), the authors consider the general trend of infestation and report upon varietal resistance, poison bait traps, the response of earworm moths to sugars, moth poisons, and poison traps or feeders, and insecticide tests, the details of the work being presented in tables and graphs. The results led to the recommendation of the following practices and measures that will aid in corn earworm injury:

"Fall plowing causes the destruction of pupal cells, crushes overwintering pupae, exposes pupae to birds and weather. The use of resistant varieties, especially Honey June in Maryland, will cause a reduction of injury. Barium fluosilicate or lead arsenate applied at sufficient intervals to keep the silk covered with poison will reduce injury 60 to 80 percent. It should not be applied to ears with tips exposed. All treated corn should be carefully husked and washed before being eaten. Corn planted early is less injured than corn planted late. Several years' observation indicate a slight depression in infestation on corn maturing around the last week of July and the first week of August; subsequently, earworm rapidly increases in abundance until cold weather."

**Report of the tomato fruit worm investigations at Marietta,** J. S. HOUSER (*Ohio Veg. Growers Assoc. Proc.*, 21 (1936), pp. 91-96).—In reporting upon a continuation of the work of the preceding year by the Ohio Experiment Station with the corn earworm as an enemy of the tomato as noted on page 824, additional information on its biology and a summary of the activities of the year in the Marietta district are presented.

Seventeen different spray and 7 dust formulas were applied and compared with untreated plats. In sprayed plats the best control was obtained by the use of arsenate of lead in which SS-3 (a sulfonated alcohol) was used as a spreader, an average of 96.2 percent of sound fruit having been obtained. In the dusted plats paris green-lime sulfur gave 95.2 percent sound fruit. These results on 5 sprayed and 5 dusted plats are based upon percentages obtained for the harvest of the entire lot of 11 pickings, but the control was largely obtained from the first three applications, July 11, 13, and 15, respectively.

**The Noctuidae of Pennsylvania: A manual,** H. M. TRETZ (*Pennsylvania Sta. Bul.* 335 (1936), pp. 164, figs. 2).—This contribution deals with moths of the family Noctuidae, which includes cutworms, armyworms, etc., to the number of 570 species and 132 varieties and forms, grouped into 206 genera, that have been taken in Pennsylvania. For every genus there is given the name of the author and a reference to the original description. For each species reference is made to the original description, varieties, synonyms, places where the species has been taken, time of appearance, its life history, if known, and food plants of the larva, if known.

Reference is given in the index to the list numbers of the genera and species of Dyar (E. S. R., 14, p. 783) and of Barnes and McDunnough (E. S. R., 37, p. 563) in their lists of North American Lepidoptera.

**A catalog of the Lepidoptera of the Pyrenees** [trans. title], J. P. RONDOU (*Ann. Soc. Ent. France*, 101 (1932), No. 3, pp. 165-244; 102 (1933), No. 3, pp. 237-316; 103 (1934), No. 3-4, pp. 257-320; 104 (1935), No. 3-4, pp. 189-258).—A systematically arranged catalog, with the localities of the species, occurrence, and host plant and feeding periods of the larvae if known. The introductory part includes a comparison of the lepidopterous fauna of the Pyrenees with that of the Alps, a six-page bibliography, and a table of the localities cited.

**The leaf mines of insects in Spain** [trans. title], M. HERING (*Eos* [Madrid], 11 (1936), No. 4, pp. 331-384, pl. 1, figs. 15).—The leaf mines of insects in Spain are described and in some cases illustrated, with the identity of the guests if known. A new genus is erected and new species of miners described.

**The vinegar gnats or pomace flies: Their relation to the canning of tomatoes**, L. P. DITMAN, E. N. CORY, and A. R. BUDDINGTON (*Maryland Sta. Bul.* 400 (1936), pp. 91-111, figs. 7).—The results of a study of vinegar gnats during the course of a survey of canning plants and of farms furnishing cannery tomatoes reported upon include the biology of *Drosophila* spp., of which *D. melanogaster* (*ampelophila*) Meig. (officially known as the pomace fly) is the most common, *D. repleta* Woll. sometimes present in great numbers, and *D. buscki* Coq. found to occur at Salisbury, Md.; observations of field infestations, without regard to species, and at canning plants; the reduction of gnat population at canning plants; the quality of raw stock; the effect of buying on grades; methods of culling, washing, and peeling; and observations on compliance with recommendations.

A figure of the suggested set-up for washing and culling tomatoes for canning is included.

**Mosquito control engineering, I-VIII** (*Engin. News-Rec.*, 117 (1936), Nos. 4, pp. 118-122, figs. 5; 6, pp. 199-201, figs. 5; 7, pp. 225-228, figs. 4; 8, pp. 266-269, figs. 5; 9, pp. 304-307, figs. 6; 10, pp. 341-343, figs. 4; 11, pp. 372-376, figs. 6; 12, pp. 404-406, fig. 1).—The first part of this contribution, by L. O. Howard, deals with the growth and importance of antimosquito work (pp. 118-122); part 2, by T. J. Headlee of the New Jersey Experiment Stations, with mosquitoes—species and habits (pp. 199-201); part 3, by R. W. Gies, with control technic and organization (pp. 225-228); part 4, by J. L. Clarke, with inland control methods (pp. 266-269); part 5, by R. J. Van Derwerker, with the salt-marsh problem (pp. 304-307); part 6, by L. L. Williams, Jr., with effective malaria control (pp. 341-343); part 7, by C. M. Adams with ending malaria in New Mexico (pp. 372-374) and W. S. Corkran with mosquito abatement in Delaware (pp. 374-376); and part 8, by J. A. LePrince with malaria and the Mississippi Valley (pp. 404, 405), and by H. F. Gray with California's campaign (pp. 405, 406).

**Studies on the fumigation for the eggs of *Sturmia sericariae* Cornalia, I, II**, H. ITO (*Res. Bul. Imp. Tokyo Seric. Col.*, 1 (1936), No. 1, pp. 1-24; *Eng. abs.*, pp. 8, 24).—Part 1 (pp. 1-8) reports upon the fumigation of the eggs of *S. sericariae* with various aromatic hydrocarbons, and part 2 (pp. 9-24) on their fumigation with naphthalene and the effects of the fumigated mulberry leaves on the silkworm.

Eggs of this tachinid parasite of the silkworm were killed by naphthalene in 3 hr. and by benzene in 5 hr. without injury to the mulberry leaves, and by both xylene and toluene in 1 hr. and by thymol in 3 hr. with injury to the leaves. The toxicity of the vapor of various aromatic hydrocarbons was found to be related to the quantities of the chemical and the time of exposure.

**Economic studies of screw worm flies, *Cochliomyia* species (Diptera, Calliphorinae)**, with special reference to the prevention of myiasis of domestic animals, E. W. LAAKE (*Iowa State Col. Jour. Sci.*, 10 (1936), No. 4, pp. 345-359, pl. 1, figs. 2).—During the course of a 5-yr. study of the predisposing causes of attack by the screwworm fly on more than 75 ranches in Menard County, Tex., the author found that among sheep and lambs wounds caused by needlegrass (*Aristida*) gave occasion for attack by flies more than any other one cause; among goats and kids the predominating cause was shear cuts; among cattle it was injuries by the horns of other cattle. Calves suffered

most as a result of exposed tissue at birth, and horses and mules from wire cuts. It is pointed out that several of the more common causes of attack are due to ranch practices that can be changed or better timed. Greater care in shearing, dehorning of cattle while they are young, removing and disposing of old barbed wire from dismantled fences instead of leaving it on the ground, and the timing of dehorning, castrating, and branding of animals, and of breeding, so that as little as possible of open sores or wounds will be exposed to flies during the season of their abundance, are particularly stressed.

The percentage of infestation was found to range from 1.38 in 1930 to 4.3 in 1932. The possibility of reducing this infestation by trapping the flies was tried out over an area of approximately 155,000 acres of ranch land in Menard County. The apparent reduction in percentage of infestation, as compared with that on a similar area of about equal size in the same vicinity, was from 2.92 to 1.58 in 1931, from 5.86 to 3.4 in 1932, and from 3.39 to 1.36 in 1933.

Trapping seemed equally effective in years of mild or moderately heavy infestation. The expense as carried out in these tests, however, is too great to justify a recommendation for its general use, but if a more attractive bait for *C. americana* and a cheaper method of operation can be developed, fly trapping may become of distinct practical value.

**Seasonal appearance and relative abundance of flies attracted to baited traps.** W. G. BRUCE and E. F. KNIPLING (*Iowa State Col. Jour. Sci.*, 10 (1936), No. 4, pp. 361-365, figs. 4).—The results of systematic fly trapping in the vicinity of Ames, Iowa, are reported on. During the season of 1933 the first flies were taken on March 3, *Phormia regina* having been the first to appear. Other early appearing species were *Calliphora erythrocephala*, the cluster fly, *Scatophaga* spp., *Fannia* spp., and *Cynomyia cadaverina*. The housefly, *Lucilia* spp., *Sarcophaga* spp., the screwworm fly, and other species made their appearance somewhat later. Their comparative seasonal abundance is graphically shown, the housefly, *P. regina*, *Lucilia* spp., the screwworm fly, and *C. cadaverina* having been met with in greatest numbers. A list is given of the flies trapped in 1933 with the dates of their appearance and of flies trapped and their relative abundance in 1933-34.

**Notes on the autecology of some fruit-flies.—II, On the mango-fly** *Chaetodacus ferrugineus* var. *dorsalis* Hendel, K. KOJISUMI and K. SHIBATA (*Jour. Soc. Trop. Agr. (Nettai Nôgaku Kwaishi)*, 7 (1935), No. 4, pp. 370-378).—This second contribution (E. S. R., 75, p. 816) reports upon *C. ferrugineus dorsalis*.

**A revision of the chalcid flies of the genus** *Perilampus* Latreille occurring in America north of Mexico, M. T. SMULYAN (*U. S. Natl. Mus. Proc.*, 83 (1936), No. 2990, pp. 369-412).—Included in this revision of the chalcid genus *Perilampus* are descriptions of 10 forms new to science. A key to the species of the genus and a known host list are included.

**Experimental studies in insect parasitism.—IV, The effect of superparasitism on populations of** *Trichogramma evanescens*, G. SALT (*Jour. Egypt. Bot.*, 13 (1936), No. 3, pp. 363-375, fig. 1).—In continuation of studies in insect parasitism (E. S. R., 73, p. 517), *T. evanescens* was found able to distinguish healthy from parasitized hosts and when few hosts were available to restrain itself for 8 hr. with a deposition of 5 percent of its available eggs.

**A reproduction phenomenon.** S. F. FLANDERS (*Science*, 83 (1936), No. 2160, p. 499).—In this contribution from the California Citrus Experiment Station, further reference (E. S. R., 75, p. 512) is made to the finding that in certain species of parasitic Hymenoptera, particularly of the genus *Coccophagus*, the males develop only as ecto- and/or endo-parasites of larvae of Hymenoptera

within homopterous insects and the females only as endo-parasites of nymphs or adults of such Homoptera (mealybugs or scale insects). "This is a remarkable differentiation in the host relations of the sexes within a species. The production of males in a pure culture of a species having such a habit necessitates the destruction of immature females since they are the only hosts of the male present in the culture. The conditions under which the destruction of the females occurs vary with the species."

"As in other species of Hymenoptera, the male develops from unfertilized eggs deposited by unmated females. These females either deposit their eggs directly on or in the immature hymenopterous host or they deposit them in the fluid media surrounding such hosts. In this fluid media the eggs remain unhatched until the hymenopterous host is in a suitable condition for attack. This peculiar phenomenon is of practical importance in the biological control of insect pests."

**Sexual dimorphism of hymenopterous eggs and larvae**, S. F. FLANDERS (*Science*, 84 (1936), No. 2169, p. 85).—Further studies of the biology of *Coccophagus lycimnia*, a parasite of lecanine scales, are said to have shown that the eggs which develop into males differ in shape from those which develop into females, the differentiation occurring during oviposition. The male egg is sometimes deposited free in the space surrounding the host. This phenomenon is known to occur in another species of *Coccophagus*, and it may also occur in a species of *Tetrastichus* parasitic on the eggs of the eastern tent caterpillar. It was observed by Williams (E. S. R., 36, p. 556) that *Tetrastichus* frequently deposited stalked eggs on the wall of a test tube. In the first and second larval instars many species of *Coccophagus* and related genera exhibit striking sexually dimorphic characters.

**The citrus red mite (spider) problem in southern California**, A. M. BOYCE (*Calif. Citrogr.*, 21 (1936), No. 11, pp. 418, 438, 439, 440, 441, fig. 1).—This is a discussion of the citrus red mite problem from the California Citrus Experiment Station. An earlier account has been noted (E. S. R., 75, p. 234).

**Ixodes ricinus in relation to its physical environment, II-IV**, J. MACLEOD (*Parasitology*, 27 (1935), Nos. 1, pp. 123-144, figs. 8; 4, pp. 489-500, figs. 2; 28 (1936), No. 3, pp. 295-319, figs. 5).—Part 2 of this contribution (E. S. R., 71, p. 821) deals with the factors governing survival and activity of the castorbean tick, and part 3 with climate and reproduction; part 4 consists of an analysis of the ecological complexes controlling distribution and activities.

The author is led to conclude that "the biotic factors in the environment of the tick *I. ricinus* exercise little effect on the geographical or local distribution of the species or on its seasonal prevalence. The local distribution is determined by edaphic factors, a wet, mossy, or peat soil and a dense mat of old vegetation or a rank growth being necessary for survival of the tick. In Britain, the critical season for survival is summer, during which the moisture factor in the microclimate acts in a limiting capacity."

## ANIMAL PRODUCTION

[Livestock investigations in California] (*California Sta. [Bien.] Rpt. 1935-1936*, pp. 54-56, 57, 58, 109-117).—Among research activities for which results were reported are the deficiencies of barley for swine feeding; the carotene and vitamin A requirements of cattle, sheep, and swine; the effect of calcium and phosphorus deficiencies in various types of animals; the effect on ruminants of rations devoid of roughages; the evaluation of numerous byproduct feeds; cattle, horse, pig, and sheep breeding problems; and sheep and lamb feeding.

The poultry studies reported deal with selection for production, inbreeding turkeys, the requirements of chicks for two new fat-soluble vitamins, the rela-

tion of certain vitamins to dermatitis in chicks and turkeys, the protein requirements of chicks and turkeys, the effect of cold storage and high temperature on eggs, the cause of "pink white" and "olive yolk" deterioration in eggs, and factors affecting the candling of eggs.

[Investigations with livestock in Hawaii] (*Hawaii Sta. Rpt. 1936, pp. 70-79, fig. 1*).—Trials with beef cattle have yielded results on the relative value of pigeonpeas and improved pastures for fattening steers when used as the only feed and when supplemented with molasses and protein concentrates, and the value of a concentrate mixture containing pineapple bran, cane molasses, cane bagasse, and soybean oil meal for fattening steers, both by L. A. Henke; and the digestibility of Napier grass, by S. H. Work.

From swine tests information was obtained on the comparative value of a pineapple bran-molasses ration v. a barley-molasses ration for fattening pigs, and the value of local fish meal as a protein supplement for swine, both by Henke and G. W. H. Goo; and the use of garbage in the fattening ration, by Henke.

Poultry tests produced results on the use of batteries for laying and breeding hens, the value of freshly cut alfalfa v. alfalfa leaf and blossom meal, the effect of variations in relative humidity on hatchability, the value of artificial illumination for the laying flock, and a comparison of colony houses and battery brooders for growing chicks, all by C. M. Bice; and the use of molasses in the ration, and cross-breeding for meat and egg production, both by Bice and B. A. Tower.

[Investigations with livestock by the Cornell Station] ([*New York*] *Cornell Sta. Rpt. 1936, pp. 81, 84-87, 131-133, 135*).—Tests with sheep have yielded information on rations and feeding methods for fattening lambs, and long v. chopped alfalfa hay for pregnant ewes, both by F. B. Morrison and J. P. Willman; the relation of feeding and management to the cause of the "stiff lamb" disease, by Willman, Morrison, and P. Olafson; the nutritive value of proteins in important feeds and typical mixed rations as determined by metabolism experiments with lambs, by Morrison, J. I. Miller, and L. A. Maynard; and temporary pasture crops for lambs, by Willman.

Other livestock experiments reported include a comparison of protein supplements and also the effect of certain vitamin supplements for growing and fattening swine, by Morrison, Willman, and H. M. Briggs; vitamin supplements for brood sows, by Willman; live weight gains per acre on beef cattle as obtained from improved pasture, by R. B. Hinman; the cause of varying colors in beef, by Hinman and C. M. McCay; cod-liver oil and muscle dystrophy in calves, by G. Davis and Maynard; and protein requirements of the work horse, and minerals for growing colts, both by M. W. Harper and R. M. Watt.

Poultry studies yielded results on the vitamin G requirements of poultry, by L. C. Norris; the relative vitamin G content of feeding stuffs used in poultry rations, by H. S. Wilgus, Jr., Norris, and G. F. Heuser; the nutritive properties of ground soybeans and of corn gluten meal, by Norris and Heuser; the protein requirements of laying hens, and the nutritive requirements of turkeys, both by Heuser; the cause and prevention of perosis in chicks and pheasants, by Wilgus and Norris; a genetic study of interior egg quality, by G. O. Hall; and the effect of temperature, relative humidity, and mechanical jarring on egg quality after short storage periods, by Hall and A. Van Wagenen.

[Livestock investigations in West Virginia] (*West Virginia Sta. Bul. 278 (1936), pp. 6, 7, 8-10, fig. 1*).—Brief reports are presented on the relative merits of first-cross and second-cross lambs by Corriedale rams, the effect on the size and quality of the carcass of creep-feeding grain to calves on pasture dur-

ing suckling as compared to no grain during suckling and finishing in dry lot on grain and alfalfa, the effect of grass on the color of beef, and corn silage studies. From poultry studies data are reported on the effect of age on egg production and egg weight and the interrelations between age of maturity, rate of production, and longevity; methods of feeding grain to pullets; the effect of high protein mash for laying hens; and the influence of diet on the incidence of perosis in chicks.

**Relation of the carotene content of certain feed materials to their vitamin A potency**, G. S. FRAPS, R. TREICHLER, and A. R. KEMMERER (*Jour. Agr. Res. [U. S.]*, 53 (1936), No. 9, pp. 713-716).—The Texas Experiment Station has compared the carotene content and vitamin A activity (as measured by a modified Sherman-Munsell method of bio-assay) in 15 samples of feed, including 7 of alfalfa meal, 5 of peanut hay, 2 of yellow corn, and 1 of Johnson grass hay. The alfalfa samples ranged from 7.3 to 63.5  $\mu\text{g}$  of carotene per gram and the peanut hay samples from 5.6 to 26.5  $\mu\text{g}$  of carotene per gram of sample. The yellow corn samples contained 1.7 and 2.6  $\mu\text{g}$  and the Johnson grass hay 9.3  $\mu\text{g}$  of carotene per gram of sample. The average vitamin A potency per microgram of carotene was 1.4, 1.3, 1.2, and 1.1 Sherman-Munsell units in alfalfa products, peanut hay, yellow corn, and Johnson grass hay, respectively. In all cases a factor of 1.2 is used to convert Sherman-Munsell units to international units of vitamin A. One  $\mu\text{g}$  of carotene in the international standard and 1  $\mu\text{g}$  of purified carotene dissolved in oil had a value of 1.4 Sherman-Munsell units, which is practically the same as for 1  $\mu\text{g}$  of carotene in the alfalfa or peanut hay.

**The effect of storage upon the vitamin A content of alfalfa hay**, M. C. SMITH (*Jour. Agr. Res. [U. S.]*, 53 (1936), No. 9, pp. 681-684).—In a study at the Arizona Experiment Station the effect of storage of baled alfalfa hay upon its vitamin A content has been determined by bio-assay. Leaves of the baled hay stored from August to November in a hay barn contained 50 percent less vitamin A than the freshly baled alfalfa. No further destruction of vitamin A occurred during subsequent storage through November, December, and January. With rising temperatures in the spring the destruction of vitamin A was again stimulated, so that after 12 months' storage the alfalfa contained only 25 percent as much vitamin A as was found in the fresh sample.

**Comparative tests on the nutritive value of a red clover-grass mixture harvested at different stages of growth** [trans. title], W. KIRSCH and H. JANFZON (*Biedermanns Zentbl., Abt. B, Tierernähr.*, 8 (1936), No. 4, pp. 354-372, fig. 1; *Eng. abs.*, p. 372).—The nutritive value of a clover-grass mixture cut at different stages of maturity has been determined on the fresh green material, silage (ensiled with 1 percent of sugar), and cured hay.

The results indicate a decrease in crude protein and an increase in crude fiber and also a decrease in the digestibility of the nutrients as the plants approached maturity. This decline in digestible nutrients was gradual in the green material and silage but showed a pronounced drop between the first and second cuttings for the hay. In comparison with the freshly cut material there appeared to be a loss of about one-third of the protein and one-half of the starch value in drying, whereas losses in the silage were slight. In digestion trials with wethers the digestibility as determined directly when these products were fed alone or indirectly when they were fed as a supplement to a basal ration were in close agreement.

**Silage production**, E. S. HOPKINS and P. O. RIPLEY (*Canada Dept. Agr. Pub.* 525 (1936), pp. 79, figs. 24).—This publication presents a popular discussion of the silage production problem, with special emphasis on the methods of growing and ensiling those crops most suitable for silage.

**Blackstrap molasses as a livestock feed**, M. G. SNELL, C. W. UPP, and R. H. LUSH (*Louisiana Sta. Circ. 19 (1937), pp. 4*).—The suitability of molasses as a feed for mules, beef cattle, hogs, dairy cattle, and poultry is discussed, and recommendations regarding proper amounts to feed and ways of feeding are offered.

**Inspection of commercial feedstuffs**, P. H. SMITH (*Massachusetts Sta. Control Ser. Bul. 85 (1936), pp. 64*).—This report presents the official chemical analyses of 1,801 samples of commercial feeding stuffs collected during the year ended September 1, 1936. In addition the physical and chemical analyses of 55 samples of oats, and the calcium and phosphorus content of a number of chick starting and growing rations are shown (*E. S. R., 74, p. 378*).

**Commercial feeding stuffs from September 1, 1935, to August 31, 1936**, F. D. FULLER and J. SULLIVAN (*Texas Sta. Bul. 532 (1936), pp. 194*).—This is the usual report (*E. S. R., 74, p. 830*) of the results of chemical analyses and microscopic examination of 3,471 samples of feeding stuffs. The results of bio-assay of 14 vitamin D carriers are also presented.

**Feeding cottonseed products to beef cattle**, compiled by C. F. CLARK (*Mississippi Sta. Bul. 317 (1936), pp. 88*).—This bulletin is an extensive compilation of experimental data from many sources relating to the feeding of cottonseed products to beef cattle. The material is grouped in 5 sections dealing with cottonseed meal as a concentrate, cottonseed cake as a concentrate, whole cottonseed as a feed, cottonseed hulls as a roughage, and other studies with cottonseed products as a feed for beef cattle.

**Fattening beef calves for market**, G. A. BRANAMAN (*Michigan Sta. Spec. Bul. 280 (1936), pp. 48, figs. 11*).—This bulletin presents the results of four series of feeding experiments with fattening beef calves. The first series compared limited grain feeding v. full grain feeding. The second determined the value of linseed meal as a supplement to a ration of shelled corn, corn silage, and alfalfa hay. The third compared shelled corn and ground barley, each separately and in combination with linseed meal, and oats plus linseed meal as supplements to corn silage and alfalfa hay, and the fourth series tested the suitability of various rations and planes of nutrition for the production of long yearling fat cattle.

It is concluded that (1) beef calves may be finished into satisfactory yearlings with considerably less than a full feed of grain when corn silage and alfalfa hay are fed, (2) it is desirable to add a high protein supplement like linseed meal to a fattening ration of corn or barley with silage and alfalfa hay, (3) high grade ground barley and No. 2 shelled corn are of similar value in the fattening ration, but heavy weight ground oats are 11 percent less valuable than the shelled corn, (4) a plane of nutrition sufficiently high to produce gains of over 1 lb. per head per day is more profitable than when calves are so fed as to gain less than 1 lb. per day, (5) higher selling price or wider margin is necessary with increased finish after a long feeding period because of the higher feed requirements for such gains, and (6) cattle that would grade good to choice in June may generally be expected to sell higher in August or September if continued on feed.

**Studies on reproduction in cattle, I, II**, J. ANDERSON (*Empire Jour. Expt. Agr., 4 (1936), Nos. 14, pp. 186–195, figs. 3; 15, pp. 197–207, figs. 2*).—Two papers from the Experimental Station, Naivasha, Kenya, are presented.

**I. The periodicity and duration of oestrus**.—The mean duration of the oestrous cycle in cattle was observed to be 20.1 days, with a range from 17.9 to 24.2 days. The mean duration of oestrus was found to be 1 hr. 20 min. The duration of oestrus had no apparent relationship to the preceding or subsequent dioestrous cycle or interoestrous periods.

II. *The influence of environmental factors on reproduction.*—In considering the possible influence of climatic and nutritional factors on the periodicity and duration of oestrus in cattle, there is evidence of a possible correlation with amount of sunshine, but no indication of correlation with rainfall or temperature. Feed supply as furnished by pastures under changing seasonal conditions is also unrelated to the frequency or duration of oestrus.

**Soybeans and soybean oilmeal for pigs,** W. L. ROBISON (*Amer. Soybean Assoc. [Proc.]*, 15 (1935), pp. 27–29).—This article presents a résumé of a number of swine feeding tests at the Ohio Experiment Station in which various amounts of soybeans and different process soybean oil meals have been included in the ration of growing and fattening pigs. The results with raw soybeans indicate that (1) they are worth more for pigs on pasture than for those in dry lot, (2) they have a higher value for shots than for younger pigs, and (3) not more than 8 to 10 percent of soybeans in the ration can be fed for any prolonged period without danger of a high percentage of soft carcasses.

The trials with different lots of soybean oil meal gave highly variable results. It appears that such factors as the temperature reached in the manufacture of the meal and the moisture content of the beans or meal when the heat is applied influence the quality of the meal for pigs. In trials with a nutlike expeller type soybean oil meal, this product was found to have a feeding value approaching that of 60-percent protein tankage. Such soybean oil meal has a considerably greater value than raw soybeans for pigs.

**Investigations on the nitrogen excretion in the urine as influenced by the consumption and elimination of water by work horses in a resting state within the limits of minimum protein requirements** [trans. title], H. NITSCHKE (*Biedermanns Zentbl., Abt. B, Tierernähr.*, 8 (1936), No. 3, pp. 243–260; *Eng. abs.*, pp. 259, 260).—The average water consumption of Shire horses at rest ranged from 20 to 30 kg daily, the amount varying with individuals, the quantity of dry feed consumed, and climatic conditions. The proportion of dry feed to water varied from 1:3.3 to 1:4.2. The total urine excretion was exceedingly small, averaging from 3 to 5 kg daily, or only from 10 to 15 percent of the water intake. In summer the urine excretion was more variable, ranging from 2.8 to 19 kg per day. The nitrogen concentration in the urine also showed a marked variation, ranging from 0.2 to 1.4 percent. On this basis the amount of total nitrogen eliminated in the urine from day to day was quite constant, totaling from 40 to 50 g for a horse at rest and receiving an above-maintenance ration.

**Thermal effect on the rate and duration of the embryonic heart beat of *Gallus domesticus*,** A. L. ROMANOFF and M. SOCHEN (*Anat. Rec.*, 65 (1936), No. 1, pp. 59–68, *figs.* 3).—The [New York] Cornell Experiment Station has studied the effect of varying the environmental temperature above or below 37.5° C. on the rate and duration of the heartbeat of chick embryos at various stages of development. It is shown that at normal temperature (37.5°) the pulse rate increased rapidly from the second to the eighth day of embryonic development and then remained almost constant during the remainder of the incubation period. Either gradual or abrupt exposure to extreme temperatures (high or low) resulted in linear changes in the rate of heartbeat. Eventually breaks occurred in the primary linear trend, followed by secondary linear changes. The sensitivity of the contractive impulses of the heart to temperature change decreased with advance in age of the embryo. In all cases of exposure to extreme temperature, except in the abrupt exposure to high temperature, there was a general increase in the duration of the heartbeat with advancing development of the embryo.

**Ether soluble lipoid phosphorus lecithin and cephalin distribution in the development of the chick,** O. E. KUGLER (*Amer. Jour. Physiol.*, 115 (1936), No.

2, pp. 287-291, figs. 2).—Based on the determination of the total ether-soluble extract, ether-soluble lipid phosphorus, lecithin, and cephalin in the yolk and in the embryo and membranes, exclusive of yolk sac, at regular intervals throughout incubation, it is evident that the phospholipid metabolism in the developing chick embryo reaches its highest stage between the fifteenth and seventeenth days of incubation. The lipid phosphorus per 100 g of embryo (dry weight) shows a rise to the ninth day, followed by a drop to the end of the incubation period. Lecithin and cephalin parallel each other, maintaining a ratio of about 3:1 in both yolk and embryo fractions throughout incubation, and show the same fluctuation trends as does ether-soluble lipid phosphorus.

**A new nutritional disease of the chick embryo**, T. C. BYERLY, H. W. TITUS, N. R. ELLIS, and W. LANDAUER (*Soc. Expt. Biol. and Med. Proc.*, 32 (1935), No. 9, pp. 1542-1546, fig. 1).—This report from the U. S. D. A. Beltsville Research Center and the [Connecticut] Storrs Experiment Station describes a disease which has been frequently encountered during recent years in the chick embryo. It is characterized by a shortness of the bones, the anteroposterior axis of the skull and the tarsometatarsi being most strikingly affected. Such abnormal embryos usually died during the third week of incubation, although they occasionally hatched and the few that have been raised lost all abnormal appearance in the course of 10 weeks.

It has been demonstrated that this disease is of nutritional origin, and that it is prevented by supplying a factor or factors in the ration of the parent stock by additions of wheat germ, liver, or whey. Permitting the birds access to direct sunlight and green range increased the activity, amount, or utilization of the factor or factors.

**Micromelia of chicken embryos and newly hatched chicks caused by a nutritional deficiency**, W. LANDAUER (*Anat. Rec.*, 64 (1936), No. 2, pp. 267-276, figs. 5).—Continuing the investigation reported above, this phase deals with the morphological and histological features of the affected chicks. The principal seat of disturbance is in the calcification and formation of periosteal bone, with only slight abnormalities observed in the growing cartilage. Characteristic symptoms of the abnormality are the replacement of the periosteal bone by unorganized detritus, a relative scarcity of osteoblasts, restriction of calcification to the periphery of the bones, low and irregular cartilage columns, and small cartilage cells. The long bones of the wings and legs are shortened to about the same extent, and the greater the degree of shortening the more abnormal is their histological structure. The ribs are similarly affected, although to a less extreme degree, but the bones of the skull appear normal. Apparently this is the first reported instance of a prenatal nutritional deficiency which results in a disproportionate stunting of the extremities.

**The multiple nature of the third factor of the vitamin B complex**, S. LEFKOVSKY, T. H. JUKES, and M. E. KRAUSE (*Jour. Biol. Chem.*, 115 (1936), No. 2, pp. 557-566, figs. 4).—This contribution from the California Experiment Station presents definite evidence that the "third factor" of the vitamin B complex necessary to supply the requirements of the rat (E. S. R., 75, p. 282), consists of two components. Details of the procedure for their separation are described. The first component prevented or cured acute dermatitis in rats but had no effect on chick dermatitis. The second component, previously described as the filtrate factor (E. S. R., 76, p. 81), prevented or cured chick dermatitis but when fed in the absence of the first component aggravated the rat dermatitis. Both components are required by the rat for normal growth, and symptoms of the deficiency of the second factor are described.

**Pellagra-like syndrome in chicks**, S. ANSBACHER, G. C. SUPPLEE, and R. C. BENDER (*Jour. Nutr.*, 11 (1936), No. 6, pp. 529-535, fig. 1).—In a series of experi-

ments employing Ration 240-H of Kline et al. (E. S. R., 69, p. 844), it is demonstrated that the use of either heat-treated commercial casein or unheated vitamin-free casein in the ration resulted in the occurrence of a pellagra-like syndrome in a high percentage of chicks. The heated commercial products sustained more rapid growth.

Supplementing the rations with a milk vitamin concentrate treated with fuller's earth to remove lactoflavine prevented the syndrome on the heated casein diet, but was less effective on the vitamin-free casein diet. Concentrates prepared from milk and retaining the lactoflavine or from rice polish entirely prevented the development of this syndrome in each instance. Supplements of crystalline vitamin B<sub>3</sub> and lactoflavine were ineffective in this connection. Apparently the factor or factors preventing this syndrome may be at least partially adsorbed on fuller's earth and are present to some extent in heated commercial casein. In opposition to the findings of Lepkovsky et al. above, the authors conclude that the factor or group of factors which prevents and cures the dermatitis in rats is identical with that which prevents the pellagra-like syndrome in chicks.

**In vitro studies on lactic acid metabolism in tissues from polyneuritic chicks,** W. C. SHERMAN and C. A. ELVEHJEM (*Biochem. Jour.*, 30 (1936), No. 5, pp. 785-793).—In this study at the Wisconsin Experiment Station samples of fresh minced brain, heart, and kidney tissue from both normal and polyneuritic chicks were used for in vitro studies on the rate of lactic acid oxidation. Measures included rate of oxygen uptake, rate of lactic acid removal, and estimation of methylene blue reduction time.

No significant differences were noted in the reaction of brain tissues from the two lots, but in avitaminous heart tissue a decreased oxygen uptake and a slower rate of lactic acid removal was observed. The rate of lactate oxidation in avitaminous brain was unaffected by the addition of vitamin B<sub>3</sub>, but a similar addition caused an increase in the rate of oxidation in avitaminous heart. Additions of pyruvic acid inhibited the rate of lactic acid dehydrogenation to a greater extent in the avitaminous heart and kidney than in normal tissue. It is suggested that the action of vitamin B<sub>3</sub> in lactate metabolism is not primarily concerned with the dehydrogenation of the lactic acid but affects it indirectly by participation in some closely associated reaction.

**In vitro action of crystalline vitamin B<sub>3</sub> on pyruvic acid metabolism in tissues from polyneuritic chicks,** W. C. SHERMAN and C. A. ELVEHJEM (*Amer. Jour. Physiol.*, 117 (1936), No. 1, pp. 142-150).—In further studies the oxygen uptake of fresh minced brain and kidney tissue from both normal and polyneuritic chicks in pyruvate substrate has been determined. The respiration of the avitaminous brain and kidney tissue in this substrate was inhibited, particularly in the case of the latter. The addition of small quantities of vitamin B<sub>3</sub> to the pyruvate substrate increased the oxygen uptake nearly to the level of that of normal tissue. This reaction was accompanied by an increased removal of the pyruvate, although not to a normal level, suggesting that the effects observed in this trial may be secondary to the participation of the vitamin in some other reaction closely associated with pyruvate oxidation.

**A study of anaerobic glycolysis in tissues from polyneuritic chicks: The negative action of vitamin B<sub>3</sub>,** W. C. SHERMAN and C. A. ELVEHJEM (*Amer. Jour. Physiol.*, 117 (1936), No. 1, pp. 151-154).—In further studies on the carbohydrate metabolism of polyneuritic chicks it is shown that fresh samples of brain, heart, kidney, liver, and skeletal muscle in vitro readily form lactic acid from glucose or glycogen under anaerobic conditions. There was no significant accumulation of pyruvic acid under these conditions. The

addition of vitamin B<sub>1</sub> had no effect on the rate of anaerobic glycolysis, indicating that this vitamin has no function in anaerobic carbohydrate metabolism and its action is limited to the oxidative metabolism of these carbohydrate intermediates.

The effect of polyneuritis in chicks upon the *vivo* rate of removal of pyruvate injected intravenously, W. C. SHERMAN and C. A. ELVEHJEM (*Jour. Nutr.*, 12 (1936), No. 3, pp. 321-328, fig. 1).—In this phase of the study sodium pyruvate was injected intravenously into normal and polyneuritic chicks. Blood analyses indicated a very rapid removal of the pyruvate from the blood of the normal chick, while a much slower rate of removal was noted in the polyneuritic lot. These results confirm the view that in polyneuritis there is a failure in the tissue metabolism of pyruvic acid.

The use of wax in the plucking of poultry, N. H. GRACE (*Ottawa: Natl. Res. Council and Dominion Dept. Agr.*, 1935, pp. 19, pl. 1, figs. 16).—This publication gives a detailed description of the various operations involved in the wax plucking of poultry. The methods have proven practical for use on the farm and in the small plant.

### DAIRY FARMING—DAIRYING

[Experiments with dairy cattle and dairy products in California] (*California Sta. [Bien.] Rpt.* 1935-36, pp. 56, 117-121).—Significant findings are described on high milk and fat production; factors involved in the development of oxidized flavor in milk; the elimination of feed flavors from milk; the improvement of quality of butter, cultured buttermilk, and ice cream; and improved methods of testing dairy products as to adequate pasteurization and detection of gelatin.

[Dairy cattle investigations in Hawaii], L. A. HENKE and G. W. H. GOO (*Hawaii Sta. Rpt.* 1936, pp. 68-70).—The results of feeding tests are briefly noted in determining the feeding value of various concentrate mixtures containing such local feeding stuffs as pineapple bran, molasses, and cane bagasse; the use of molasses in improving roughage consumption; and the comparative value of green Sudan grass v. green Napier grass.

[Investigations with dairy cattle and dairy products by the Cornell Station] (*[New York] Cornell Sta. Rpt.* 1936, pp. 80, 81, 82, 83, 94-96, 97-99).—Dairy cattle studies gave results on the influence of quality and quantity of protein in the concentrate ration on the production of dairy cows fed hay and corn silage, by G. W. Salisbury, F. B. Morrison, E. S. Savage, E. S. Harrison, and S. H. Work; raising dairy calves on calf pellets and calf starters, by Savage, P. E. Newman, and Harrison; the influence of coconut oil meal and palm-kernel oil meal on the percentage of fat in cow's milk, by Savage, Harrison, L. A. Maynard, and Work; and bull indexes, by Savage and C. F. Crowe.

From investigations with dairy products results are reported on the specific heat of fat globules in milk, by P. F. Sharp and A. H. Rishoi; the relation of ascorbic acid to the development of oxidized flavor in milk, by Sharp, E. S. Guthrie, and G. M. Trout; the quantitative determination of lactic acid in butter, by H. C. Troy and Sharp; a vacuum method of cooling milk and cream, by Guthrie; proteolytic bacteria in milk, by C. N. Stark, H. J. Brueckner, and P. Stark; varieties of *Streptococcus lactis*, by J. M. Sherman and E. S. Yawger, Jr.; and nonpathogenic hemolytic streptococci, by Sherman, P. Stark, and C. F. Niven, Jr.

[Experiments with dairy cattle and dairy products in West Virginia] (*West Virginia Sta. Bul.* 278 (1936), pp. 13-16).—Dairy cattle studies have yielded information on simplified rations for dairy cows, the phosphorus require-

ments of heifers during gestation and lactation, the cost of raising dairy calves, and the comparative value of Sudan grass v. sweetclover for pasture.

From dairy products studies results are reported on the cause and prevention of oxidized flavor in milk and the cause of bitter flavor in sour cream.

**Feeding dairy cows**, R. H. LUSH and E. W. NEASHAM (*Louisiana Sta. Circ.* 18 (1937), pp. 43, figs. 5).—This is primarily a revision of Louisiana Station Circular 1 (E. S. R., 63, p. 567), with supplementary data.

**An experiment in chopping alfalfa hay at the time of storage**, T. E. WOODWARD and J. B. SHEPHERD (*Jour. Dairy Sci.*, 19 (1936), No. 11, pp. 697-706, figs. 2).—The U. S. D. A. Bureau of Dairy Industry has made a comparative study of finely chopped ( $\frac{1}{4}$  in.), coarsely chopped ( $\frac{3}{4}$  in.), and long alfalfa hays. These hays contained from 25 to 27 percent moisture when stored.

Approximately three times as much finely chopped and twice as much coarsely chopped hay could be put in a given space as hay in the long form. The finely chopped hay heated much more and the coarsely chopped hay somewhat more than the long hay. The chopped hays lost all trace of green color during storage, the fine hay ranging from black to brown and the coarse hay being light brown, whereas a considerable percentage of original green color was retained in the long hays. Carotene loss was extensive in all lots, but somewhat greater in the chopped hays. The loss of dry matter during storage, while moderate in all cases, was highest (6.5 percent) in the finely chopped lot. The black chopped hay was the least palatable of the various lots, while the long hay proved somewhat more efficient than the chopped hays in tests with milking cows.

**Silage crops for dairy cattle**, W. B. NEVENS (*Illinois Sta. Circ.* 463 (1936), pp. 16, fig. 1).—This circular briefly discusses the advantages of silage as a feed for dairy cattle and the adaptability of corn and certain other crops for ensiling. Practical suggestions are offered on the proper stage of maturity for harvesting, methods of putting crops into the silo, the prevention of spoilage, estimating the money value of silage, and measuring the capacities of silos.

**The influence of grass silage prepared with and without mineral acid on the acid base equilibrium, health, and production of dairy cows** [trans. title], E. BROUWER and N. D. DIJKSTRA (*Biedermanns Zentbl., Abt. B, Tierernähr.*, 8 (1936), No. 4, pp. 340-353, figs. 2; *Eng. abs.*, p. 353).—Two groups of 12 milking cows each were fed ordinary grass silage and mineral acid grass silage, respectively. The ordinary silage was of low quality, while the acid silage was well preserved. Digestion trials showed little difference in the digestibility of the fat, nitrogen-free extract, and fiber of the two lots, but the digestibility of the protein in the ordinary silage was considerably lower than in the acid silage. Feeding the acid silage (pH 3.7 to 4) without supplementary bases resulted in lowering the pH of the urine to about 5.5 and a marked increase in urinary ammonia accompanied by a sharp reduction in the carbonic acid of the blood. This condition was readily corrected by adding either chalk or soda to the ration. Feeding acid silage caused a decrease in live weight of the animals and was reflected in the quality of the product by poor creaming quality and an increase in rennet coagulability. For the short duration of this experiment the level of milk production and the fat and total solids content of the milk was unaffected by the abnormal acid base equilibrium resulting from feeding acid silage.

**Soybeans and soybean products for dairy cows**, J. W. WILBUR and J. H. HILTON (*Amer Soybean Assoc. [Proc.]*, 15 (1935), pp. 24, 25).—This article presents a résumé of a number of trials conducted at the Indiana Experiment

Station. Data are presented on the comparative values of soybean oil meal and linseed meal in a dairy ration, the influence of soybeans on the fat content of milk, and the effect of time of harvest on the feeding value of soybean hay.

**Dried blood as a source of protein for dairy cows,** J. G. ARCHIBALD (*Massachusetts Sta. Bul.* 334 (1936), pp. 7).—In a further study to determine the value of slaughterhouse byproducts as a source of protein for milking cows (E. S. R., 74, p. 386), two groups of 11 cows each were fed by the double reversal method over four 40-day periods. Approximately equal amounts of digestible protein were supplied in each ration, 10 percent cottonseed meal and 10 percent soybean meal in the control ration being replaced by 10 percent dried blood and 10 percent cornstarch in the test mixture. No difficulty was experienced in getting the cows to eat the dried blood ration. There was no significant difference between the rations with reference to general appearance of the cows, milk production, composition, flavor, or curd tension of the milk. A slightly significant difference in live weight gains in favor of the control ration was noted. It is concluded that dried blood may be considered a satisfactory substitute for a mixture of cottonseed meal and soybean meal.

**The metabolism of galactose.—II, The synthesis of lactose by slices of active mammary gland in vitro,** G. A. GRANT (*Biochem. Jour.*, 29 (1935), No. 8, pp. 1905–1909).—In experiments at the Lister Institute, London, slices of freshly desiccated mammary gland of freely lactating guinea pigs were immersed in physiological salt solutions containing different hexoses. It is shown that glucose is readily converted into lactose, while there was but little evidence of synthesis from either fructose, mannose, or galactose. It seems likely that any of these forms must be converted into glucose before they can serve as substrates for the synthesis of lactose. A slight synthesis of organic phosphates obtained in one instance from added glucose and phosphate is noted.

**Mineral metabolism in the calf and the addition of inorganic minerals to the calf's diet,** E. J. SHEEHY and B. J. SENIOR (*[Irish Free State] Dept. Agr. Jour.*, 34 (1936), No. 1, pp. 1–32, figs. 5).—A series of feeding trials and balance experiments conducted at University College dealing with the mineral metabolism of calves weaned from milk at 7 weeks of age and reared on a dry concentrate and hay diet is reported. A deficiency of sodium chloride in the ration was reflected in unthrifty condition, harsh coat, and low retention of both calcium and phosphorus. Supplements are deemed particularly necessary when low quality roughage is supplied. Calcium deficiency which frequently resulted from feeding poor quality hay or very low hay consumption decreased the appetites, retarded shedding of old hair, and resulted in a low retention of both calcium and phosphorus. Supplying inorganic calcium sufficient to raise the calcium-phosphorus ratio above unity corrected the calcium deficiency and also increased phosphorus retention. No evidence of phosphorus deficiency occurred when a large part of the ration consisted of cereals and byproducts. The addition of supplemental iron or iodine failed to improve the ration. The addition of cod-liver oil to a diet including poor quality hay increased the digestibility of the entire ration and improved the retention of both calcium and phosphorus. However, no beneficial effects were noted from adding cod-liver oil to a ration containing good quality roughage.

**Milk and milk products,** C. H. ECKLES, W. B. COMBS, and H. MACY (*New York and London: McGraw-Hill Book Co.*, 1936, 2. ed., pp. XIII+386, figs. 92).—The second edition of this text (E. S. R., 62, p. 463) retains the same arrangement of chapters as the original edition, but has been revised to include certain changes and developments in the dairy industry and advances in the knowledge of fundamental facts concerning milk and its products,

The influence of the physical state of the fat on the calculation of solids from the specific gravity of milk, P. F. SHARP and R. G. HART (*Jour. Dairy Sci.*, 19 (1936), No. 11, pp. 683-695, fig. 1).—This report from the [New York] Cornell Experiment Station, in considering certain variables which are responsible for lack of agreement and reproducibility of results in calculating the total solids of milk from the butterfat content and the specific gravity, has shown that the specific gravity at 15° C. is markedly influenced by the temperature to which the milk has been previously subjected. This condition is due to a lag in the change of the physical state of the fat in the globules as the temperature is adjusted to this point. This effect becomes more pronounced as the fat content of the milk increases. The authors propose that the specific gravity determination on milk be made at 30° after previously warming the milk to 45° for ½ min., under which condition the fat will be in a liquid state. By following this procedure the equation

$$\text{Total solids} = 1.2537 \text{ fat} + 0.2680 \frac{\text{lactometer}}{\text{sp. gr. of milk}}$$

has been found to give close agreement between calculated and actual total solids content (as determined by drying) in a comparison of 421 samples representing a wide range of conditions regarding source of milk, season, and breed.

To what extent do tests from composite samples and fresh samples of milk agree? D. MEADE and J. N. LECKIE (*Milk Plant Mo.*, 25 (1936), No. 8, pp. 28-30).—In a study at the Maryland Experiment Station the test of regular 10-day composite samples was compared with the test on fresh milk samples taken on 3 days of each month. The trial included the milk from nine farms and extended over a 6-mo. period. The periodic fresh samples averaged 0.09 percent higher than the average of the composite samples, 60 percent of the composite samples testing lower than the fresh samples, 12 percent the same, and 27 percent higher. There was an average maximum range of 1.01 percent butterfat in the fresh samples over the entire period, as compared with an 0.84 percent range in the composites.

Why do fat tests vary? A perpetual query, J. C. MARQUARDT and H. L. DURHAM (*Farm Res. [New York State Sta.]*, 3 (1937), No. 2, p. 8).—With further reference to this subject (E. S. R., 76, p. 237), this article presents data indicating that the methods of sampling at the milk plant may produce slight variations. In a comparison of three methods 31.5 percent of the samples gave exact checks by the three methods, 80 percent checked within 0.1 percent, and 95 percent within 0.2 percent, indicating the small significance of the variations in tests due to commonly used sampling methods.

Effect of sunlight on some milk and cream products, F. J. DOAN and C. H. MYERS (*Milk Dealer*, 26 (1936), No. 1, pp. 76, 78, 80, 82, 84-87, figs. 2).—In a study at the Pennsylvania Experiment Station, it is shown that exposure of certain milk and milk products to sunlight ordinarily results in the development of off-flavors designated either as burnt or tallowy. These two appear to be distinct flavor changes, the former predominating in low fat products, the latter in high fat products. Paraffined paper milk bottles as used in this study offered considerably more protection to skim milk, whole milk, and buttermilk against the development of burnt flavor than was afforded by clear glass bottles. However, paper bottles were no protection to whole milk or cream against tallowy flavors caused by sunlight. Blue- and green-colored paper bottles or blue and green Cellophane wrappers on paper bottles retarded the development of both burnt and tallowy flavors. Off-flavors were detected first

in the milk in glass containers, but the intensity of tallowy flavor in milk and cream was greater in the paper bottle.

**Off-flavored milk: A problem of animal nutrition,** J. A. ANDERSON (*Milk Dealer*, 26 (1936), No. 1, pp. 60, 62, 64, 66).—Results are presented which indicate that the common occurrence of rancid and oxidized flavors in milk is fundamentally a matter of feeding. Such off-flavors were much more prevalent in milk from a herd receiving a ration of corn silage, field-cured alfalfa hay, and grain than when machine-dried alfalfa hay or fresh carrots was added to the ration. The addition of massive doses of a vitamin A concentrate to the ration gave questionable results, definitely less satisfactory than those obtained by feeding the machine-dried alfalfa or carrots: It seems apparent that these last-named feeds carry a factor or factors necessary for the production of milk of good flavor, and that a lack of these results in certain off-flavors. While this factor is not definitely identified, carotene seems to be very important in this connection.

**The bacteriological grading of milk,** G. S. WILSON ET AL. (*[Gt. Brit.] Med. Res. Council, Spec. Rpt. Ser. No. 206* (1935), pp. 392, figs. 29).—This extensive report gives a full account of a critical inquiry into the validity of the methods available for bacteriological examination and grading of milk. Based on experimental evidence obtained in the course of this study, the authors point out the shortcomings of the plate count, the coliform count, and other common tests used in determining the sanitary quality of milk. A modification of the methylene blue reduction test is described, and results are presented to indicate that it is particularly well adapted for grading milk as to its suitability for human consumption.

**Preservation of milk by gas pressure,** A. C. DAHLBERG (*Farm Res. [New York State Sta.]*, 3 (1937), No. 2, p. 14).—The author points out the similarity between the process, recently patented in Germany, of preserving milk by subjecting it to a pressure of approximately 150 lb. per square inch by oxygen gas and the process reported by the New York State Experiment Station 20 yr. ago (E. S. R., 19, p. 573), the principal difference being the use of carbon dioxide instead of oxygen in the latter. In view of the similar results obtained by these methods, it is suggested that the pressure involved rather than the presence of a specific gas is the main factor in inhibiting bacterial growth. Either process is considered to have a very limited practical application.

**Methods of caring for farm separators and their influence upon the quality of cream,** C. K. JOHNS (*Sci. Agr.*, 16 (1936), No. 7, pp. 373-390; *Fr. abs.*, p. 390).—When the separator bowl is held unwashed between the evening and morning separations at a temperature of 18° C. (64.4° F.), thorough flushing of the bowl with cold water following the evening separation and again prior to the morning separation reduces bacterial contamination from the bowl to a low figure, and a similar flushing with hypochlorite solution practically eliminates contamination.

When the bowl is held at 28°, however, such flushing will not prevent serious contamination of the cream, although hypochlorites are considerably more effective than cold water in this respect. It is shown that cream samples sour more readily than milk samples containing an equivalent bacterial content at 15.5°. Coliform organisms apparently had little influence on the rate of acid production at this temperature.

**Cheese ripening studies** (*Canad. Jour. Res.*, 14 (1936), No. 9, Sect. B, pp. 311-319; 320-324).—Continuing this series, two additional studies are reported (E. S. R., 73, p. 235).

*The influence of yeast extract on the types of streptococci found in starters*, B. A. Eagles, O. Okulitch, and A. G. Campbell (pp. 311-319).—In this phase of the study an active lactic acid cheese starter was carried through 20 successive transfers in fresh skim milk alone and in the same skim milk enriched with 0.15 percent yeast extract. Suitable dilutions of each were then plated on peptonized milk gelatin and peptonized milk gelatin plus 0.15 percent yeast extract and incubated for 7 days, after which time cultures were isolated for further study. The most significant result of the yeast enrichment was the development of a much larger proportion of slow acid-producing strains of streptococci which had the ability to ferment the more complex carbon sources, including salicin, maltose, starch, dextrin, and sucrose. The strains of lactic acid streptococci isolated are described, including six new strains and one new species.

*The influence of the configurational relations of the hexoses on the sugar-fermenting abilities of lactic acid streptococci*, O. Okulitch and B. A. Eagles (pp. 320-324).—In this phase a vigorous strain of *Streptococcus cremoris* was used in inoculating broths containing fructose, glucose, mannose, galactose, sucrose, maltose, lactose, dextrin, starch, and salicin, respectively. Repeated serial transfers in each sugar broth were made at 48-hr. intervals, and at each transfer milk tubes were inoculated with each culture and the time required to clot the respective milk tubes determined. After a few transfers it is shown that certain of the sugars exerted an inhibitory influence on the rate and amount of acid production in milk. Glucose and salicin showed the strongest inhibitory effect, and after 11 transfers in either of these the organism completely lost its ability to ferment lactose, while mannose and fructose also exerted considerable inhibitory action. Galactose or lactose, while failing to inhibit this activity completely, did exert a restraining influence. It appears that the inhibitory activity of glucose or one of its metabolic products may be the cause of the sudden or gradual loss of vitality in the starters.

*A comparison of pressure and centrifugal homogenization of ice cream mixes*, J. C. HENING (*Jour. Dairy Sci.*, 19 (1936), No. 11, pp. 707-714, figs. 2).—The New York State Experiment Station has studied the comparative effects of 2-stage homogenization (using various pressures on each stage) and centrifugal homogenization on the viscosity, average size of fat globules, and the degree of clumping of fat globules in ice cream mixes and the quality of the resulting ice cream. Pressure homogenization at 2,000-500, 1,200-400, and 900-300 lb. gave mixes very similar in viscosity and size of globules to those centrifugally homogenized. However, the former showed considerable clumping of the fat globules, whereas the latter contained no such clumps. When the mixes contained gelatin the resulting ice creams under each treatment were very similar in body and texture. When the mixes did not contain gelatin the range of treatments outlined above was not effective in increasing viscosity of the mix, and the resulting ice cream was coarse. The viscosity of the centrifuged mixes and the quality of the ice cream from such lots failed to equal that of the unhomogenized mixes. Higher homogenization pressures were effective in increasing the viscosity of mixes containing no gelatin. Data are presented on the effect of maintaining a constant pressure on each stage while employing a range of pressures on the other stage.

## VETERINARY MEDICINE

*History of veterinary medicine*, E. LECLAINCHE (*Histoire de la médecine vétérinaire*. Toulouse: Office du Livre, 1936, pp. XV+812, [fig. 1]; rev. in *Jour. Compar. Path. and Ther.*, 49 (1936), No. 2, pp. 181, 182).—Part 1 considers the the origin of veterinary schools through the Middle Ages and the period of the

Renaissance (pp. 7-227); part 2, the modern veterinary schools and colleges (pp. 229-812).

**Veterinary military history of the United States, with a brief record of the development of veterinary education, practice, organization, and legislation, I, II,** L. A. MERRILLAT and D. M. CAMPBELL (*Kansas City, Mo.: Haver-Glover Labs., 1935, vols. 1, pp. 620, figs. 291; 2, pp. 621-1172, figs. 168; rev. in Vet. Med., 30 (1935), Nos. 10, pp. 457-460, 11, pp. 513-516; Jour. Amer. Vet. Med. Assoc., 87 (1935), Nos. 5, pp. 586-589, 6, pp. 684-686*).—Following an introduction (pp. 23-117), the several parts of volume 1 deal with the subject as follows: Prior to the Civil War, 1792-1860 (pp. 117-146); Civil War and reconstruction, 1861-79 (pp. 147-190); Army veterinarians civilian employees with enlisted status, 1879-1901 (pp. 191-340); Army veterinarians civilian employees with commissioned status, 1901-16 (pp. 341-470); and Army veterinary service, zone of interior, 1916-20 (pp. 471-620). Volume 2 takes up the veterinary service of the American Expeditionary Forces, 1916-20 (pp. 627-910), and the present Army Veterinary Corps, 1920-35 (pp. 911-976), followed by lists of Army veterinarians, 1866-1935 (pp. 977-1145).

Chapters have been contributed to volume 1 by J. P. Turner (pp. 267-278). C. J. Marshall (pp. 483-490), and C. E. Cotton (pp. 491-502) and to volume 2 by W. H. Wright (pp. 789-798).

**Treatise on exotic veterinary and comparative pathology.—III, Sporadic diseases, intoxications, food deficiency diseases, etc.,** G. CURASSON (*Traité de pathologie exotique vétérinaire et comparée.—III, Maladies sporadiques, intoxications, carences. Paris: Vigot Bros., 1936, pp. 614, figs. 3*).—In this third volume of the work previously noted (*E. S. R., 75, p. 690*), particular attention is given to poisonous plant intoxications, including an extended consideration of the toxic species by families and genera. Chapter 20 (pp. 544-602) complements volumes 1 and 2. Bibliographies accompany the several chapters.

**Bernhard Bang: Selected works,** edited by V. ADSESEN (*Köbenhavn (Copenhagen): Levin & Munksgaard; London: Oxford Univ. Press, 1936, pp. XIV+560, pls. 7, figs. 4*).—This selection of the most important of the scientific works of the late B. Bang is presented in three groups, in each of which they are arranged in chronological order. The first (pp. 1-179) comprises Bang's investigations on a series of important animal diseases, including actinomyces, mastitis in cattle, infections caused by the bacillus of necrosis, endocarditis in swine erysipelas, epizootic abortion, chronic bacterial enteritis in cattle (Johne's disease), and abortion due to tuberculosis; the second group (pp. 180-236) comprises his investigations on tuberculosis of the udder and on tuberculous milk; and the third group (pp. 237-560) comprises a selection of his works on tuberculin and its application by the method that he developed for combating tuberculosis in cattle.

**Variations and diseases of the teeth of animals,** F. COLYER (*London: John Bale, Sons & Danielsson, 1936, pp. VIII+750, figs. [1021]*).—Variations of the teeth in number and shape and in the position of the teeth of animals, considered systematically by orders, which take up the greater part of the work, are followed by accounts of the abnormal eruption of teeth, injuries of the jaw, injuries of the teeth, overgrowth of teeth, hypoplasia of the teeth, caries of the teeth, loss of the tooth tissue from causes other than caries, dento-alveolar abscess, progressive destruction of the tooth sockets—parodontal disease, and odontomes.

**A rapid test for the detection of latent and clinical mastitis,** G. C. HOLM and D. F. EVELETH (*Vet. Med., 32 (1937), No. 1, pp. 20, 21*).—A description is given of a color test developed for the field diagnosis of both clinical and latent mastitis.

**Rickettsias and rickettsioses** [trans. title], L. BALOZET (*Rev. Gén. Méd. Vét.*, 45 (1936), No. 535, pp. 385-408, figs. 3).—This contribution includes a tabulation of the known pathogenic forms of *Rickettsia* (15 in number), the diseases caused, their geographical occurrence, natural (so far as known) and experimental vectors, natural hosts, hosts experimentally susceptible, and serological reaction.

**The incidence and pathology of tumours of domesticated animals in South Africa**, C. JACKSON (*Onderstepoort Jour. Vet. Sci. and Anim. Indus.*, 6 (1936), No. 1, pp. 460, figs. 187).—This contribution (E. S. R., 75, p. 538) reports upon a study of the Onderstepoort collection of neoplasms, with special reference to their histopathology.

**A compendium of parasitology, I, II**, E. BRUMPT (*Précis de parasitologie. Paris: Masson & Co., 1936, 5. ed., rev., vols. 1, pp. XII+1082, pls. 4, figs. [576]; 2, pp. 1083-2139, figs. [525]*).—A completely revised and enlarged edition of the work previously noted (E. S. R., 48, p. 774).

**Cutaneous reactions and the diagnosis of parasitic diseases (nonbacterial)**, J. CALLOT (*Réactions d'hypersensibilité cutanée et diagnostic des maladies parasitaires (non bactériennes). Paris: Vigot Bros., 1934, pp. 173*).—This review is presented with a 28-page list of references to the literature.

**Synopsis of the helminths of domestic animals in Brazil** [trans. title], C. PINTO and J. LINS DE ALMEIDA (*Campo [Rio de Janeiro]*, 6 (1935), No. 8, pp. 54-63, figs. 11).—This contribution includes annotated host lists of the helminth parasites of domestic animals in Brazil and a bibliography of 59 titles.

**The effects of natural factors, rain and sun, on survival of eggs and larvae of animal parasites under tropical conditions**, L. A. SPINDLER (*Puerto Rico Sta. Agr. Notes No. 74* (1936), pp. 4).—Observations and experiments conducted by the U. S. D. A. Bureau of Animal Industry in cooperation with the station from May 14 to August 6, 1936, in which eggs of the swine roundworm *Ascaris suis* and the swine thorny-headed worm *Macracanthorhynchus hirudinaceus* were used, together with infective larvae of the swine kidney worm *Stephanurus dentatus*, the swine nodular worm *Oesophagostomum dentatum*, the sheep stomach worm *Haemonchus contortus*, the dog hookworm *Ancylostoma caninum*, and various undetermined species of horse strongyles (Strongylidae), are reported upon.

Most parasite eggs and larvae were found to die quickly on unshaded grassed areas, but disappeared sooner on bare soil partially shaded and even more rapidly on unshaded bare soil. The eggs of the swine roundworm were quickly killed by sunlight, while heavy rainfall cleared the pasture areas of the eggs and larvae. Horse strongyles were found only in and close to piles of manure. It appears that the utilization of sunlight and heavy rains is important in parasite control.

**Disinfection and sterilization**, E. C. MCCULLOCH (*Philadelphia: Lea & Febiger, 1936, pp. 525, figs. 53*).—This work is presented in 19 chapters, each of which is accompanied by a bibliography.

**[Report of work in animal parasitology and pathology]** (*California Sta. [Bien.] Rpt. 1935-36, pp. 90-97*).—The work of the biennium 1935-36 with diseases and parasites of livestock referred to (E. S. R., 72, p. 689) includes the use of tuberculin in the diagnosis of and of B. C. G. in vaccination against tuberculosis of cattle, whey tests for the diagnosis of and use of low virulent culture for calfhood (E. S. R., 75, p. 106) and swine vaccination against Bang's disease, tick transmission of (E. S. R., 75, p. 254; 76, p. 249) and intravenous injections of sodium carodylate and glucose solution in treating cattle for anaplasmosis, vesicular exanthema of swine (E. S. R., 74, p. 392; 75, p. 101),

the seasonal incidence of *Ostertagia circumcincta* in sheep on irrigated pastures and the status and control of *Trichostrongylus axei* in sheep, vaccination of poultry for fowl pox (E. S. R., 75, p. 110), infectious coryza of poultry (E. S. R., 76, p. 697), pullorum disease (E. S. R., 73, p. 396), a protozoal disease of poultry a cause of poultry mortality, and the tick *Ornithodoros hermsi* known to be a vector of human relapsing fever (E. S. R., 74, p. 695; 76, p. 370).

**Animal diseases** (*West Virginia Sta. Bul.* 278 (1936), p. 8).—Brief notes are given on the negative effect on pigs of vitamin A in the ration as regards susceptibility to infestation by roundworms and on the use in sheep of copper sulfate for control of gastrointestinal parasites and of an oil extract of pyrethrum for lungworms.

[The fourth report of the director of the Institute of Animal Pathology, University of Cambridge, 1934–35] (*Cambridge Univ., Inst. Anim. Path. Rpt. Dir.*, 4 (1934–35), pp. 1–102, 212–304, pls. 13, figs. 8).—Contributions presented in this fourth report (E. S. R., 70, p. 825) are as follows: Contagious Pustular Dermatitis of Sheep: Vaccination, by R. E. Glover (pp. 1–15); Observations and Experiments With Myxomatosis Cuniculi (Sanarelli) to Ascertain the Suitability of the Virus to Control the Rabbit Population, by C. J. Martin (pp. 16–38); Fowl Paralysis—I, The Results of an Investigation Into Thirty-Eight Outbreaks, by F. Blakemore (pp. 39–50), and II, Experiments on Transmission, by F. Blakemore and R. E. Glover (pp. 51–64); The Persistence of *Brucella* in the Aborted Foetus and Its Membranes (pp. 65–71) and Examination of Faeces and Urine of Cows for the Presence of *Brucella abortus* (pp. 72–78), both by T. J. Bosworth; The Effect on *Cl[ostidium] welchii* Toxins of a Substance Present in the Normal Intestine, by T. J. Bosworth and R. E. Glover (pp. 79–93); Avian Tuberculosis in Cattle, by R. E. Glover and A. S. Griffith (pp. 94–102); Some Observations on the Physiological Actions of *Cl[ostidium] welchii* Toxins, by J. A. Nicholson (pp. 212–226); The Pathology of "Swayback", a Congenital Demyelinating Disease of Lambs With Affinities to Schilder's Encephalitis, by J. R. M. Innes (pp. 227–250); Preliminary Experiments in Calves on the Immunity Conferred by the Subcutaneous Inoculation of *Mycobact[erium] tuberculosis* in Oily Excipients, by J. B. Buxton and R. E. Glover (pp. 251–261); Duration of the Immunity Produced in Calves by the BCG Vaccine, I, by J. B. Buxton, R. E. Glover, and A. S. Griffith (pp. 262–279); and The Effects of Some Natural Factors on the Second Ecdysis of Nematode Infective Larvae, by G. Lapage (pp. 280–304).

**Studies on aseptically drawn milk from Bang's disease positive and Bang's disease negative cows**, H. B. MORRISON and F. E. HULL (*Jour. Dairy Sci.*, 19 (1936), No. 7, pp. 432, 433).—In continuation of their work in Kentucky (E. S. R., 74, p. 257) the authors report upon a study in two commercial dairies, samples being secured from each quarter of the udders of 184 cows.

A comparison of the (1) bromothymol blue reaction, (2) leucocyte content, (3) agglutination, and (4) examination for the presence of streptococci, made on the same sample, showed "the largest group among the positive cows to be positive to all four tests and the largest group from the negative cows to be negative to all four tests. It appears from these results that cows positive to Bang's disease are subject to considerably more udder trouble than cows negative to Bang's disease. The results secured from these herds indicate that proper care and management of herds containing Bang's disease positive and negative cows may influence the amount of udder trouble to a considerable extent."

**The vaccinal immunization of cattle for Bang's disease**, D. B. MEYER and I. F. HUDDLESON (*Michigan Sta. Tech. Bul.* 153 (1936), pp. 25).—The results of a 5-yr. study of a vaccine made from a selected nonvirulent strain of *Brucella*

*abortus* in cattle of an age varying from a few weeks to many years and situated in farm herds, conducted from 1929 by the U. S. D. A. Bureau of Animal Industry and the station cooperatively, are presented, the details being given in tables. The particular culture used is said to have been studied intensively as to its virulence and immunizing value at the station since 1921.

"During the study there was no evidence obtained of any harmful effects resulting from the vaccine on the breeding efficiency or milk production of the animals. Furthermore, it has been found that the strain of *B. abortus* used in the vaccine is nonpathogenic for human beings. Data pertaining to the effectiveness of the vaccine in immunizing cattle against infection from *B. abortus* have been analyzed mathematically using the (*chi*)<sup>2</sup> equation for testing independence. A (*chi*)<sup>2</sup> value of 24.5 was obtained by solving the equation. A number as great as this is proof that there is a significant difference in the incidence of infection in the vaccinated animals and those in the control groups. The presence of *Brucella*-immune opsonins in high titer in the blood of cattle indicates the degree of active immunity against Bang's disease."

**The incidence of streptococcic mastitis among dairy cattle**, C. S. BRYAN (*Vet. Med.*, 32 (1937), No. 2, pp. 70-74; *Ger., Fr. abs. p. 74*).—In a survey made by the Michigan Experiment Station covering 322 herds of a typical milkshed, 86 percent of all the herds had streptococcic mastitis and 26.2 percent of all milking cows tested were infected with the streptococci of mastitis. The incidence of infection was not influenced by the size of the herd, for some large and some small herds were found to have a high percentage of cows infected and others had a low incidence of infection.

**Do all bovine udders contain mastitis organisms?** G. J. HUCKER (*Farm Res. [New York State Sta.]*, 3 (1937), No. 2, p. 2).—In a search for the original source of the mastitis organism, about 50 udders were removed aseptically from cows and heifers and determined by post mortem not to show any changes in the tissue which would indicate the presence of mastitis. By special laboratory manipulations, these udders were cultured and it was found possible to isolate one of the mastitis streptococci (of which there are three known types or varieties) from every udder which had passed through one or more lactation periods. It would appear that all cows which have passed through a lactation period carry these mastitis organisms embedded in the udder tissue. Active infection is set up only when the cow's resistance is lowered by injury or other cause.

**A report on a control program for bovine infectious mastitis based on segregation of infected animals**, E. O. ANDERSON and W. N. PLASTRIDGE (*Jour. Dairy Sci.*, 19 (1936), No. 7, p. 432).—In further work with infectious bovine mastitis (*E. S. R.*, 75, p. 845), data collected before and after the adoption of the program of segregation based upon periodic examinations, chiefly bacteriological, and segregation of animal shedding streptococci identified as *Streptococcus agalactiae* by the method previously noted (*E. S. R.*, 76, p. 249) are reported upon.

**Infectious bovine mastitis: Report on a control program based on segregation of infected animals**, W. N. PLASTRIDGE, E. O. ANDERSON, F. J. WEIBERTER, and R. E. JOHNSON (*Jour. Dairy Sci.*, 19 (1936), No. 10, pp. 641-650).—This contribution from the [Connecticut] Storrs Experiment Station reports further (see above) upon a control program, a description of which has been noted (*E. S. R.*, 73, p. 104). By the use of this segregation plan the annual rate of spread of infectious streptococcal mastitis in herds may be reduced from 50 to 100 percent. While the rate of spread of infection is materially reduced by segregating infected animals at one end of the milking string and milking them last, complete separation is necessary to prevent entirely the spread of infec-

tion. Herds free from *Streptococcus mastitidis* (group A) (= *S. agalactiae*) may be established by segregation of the normal animals, disposal of infected individuals, and replacement by first calf heifers that have not been exposed to infection following parturition. The results presented support the opinion that it is possible to establish and maintain a herd free from the organism generally recognized as *S. agalactiae*.

**Production of white spotted kidneys in calves**, L. A. MOORE and E. T. HALLMAN (*Jour. Dairy Sci.*, 19 (1936), No. 7, pp. 434, 435).—The authors have found that "when calves at 30 days of age are placed on a ration of skim milk, cornstarch, bran, yeast, mineral, or similar rations which are low in their vitamin A content, so-called white spotted kidneys develop in many of the calves. During the past 4 yr. some 30 cases have been noted on autopsy. Macroscopically and microscopically the lesions are similar to those previously described which develop when colostrum is withheld from the newborn calf. The condition is also associated with the development of pneumonia and scours.

"The calves usually come to autopsy at from 90 to 150 days of age. The feeding of carotene in the form of 'caritol' seems to possess some preventative properties which would indicate that the condition may be related to vitamin A deficiency. Experiments are now in progress to establish the deficiency."

**A treatment for scours in calves**, J. N. SHAW and O. H. MUTH (*North Amer. Vet.*, 17 (1936), No. 7, pp. 35-38).—In work at the Oregon Experiment Station, *Lactobacillus acidophilus* milk cultures proved successful in bringing about a rapid recovery in 34 cases of dysentery in calves. Four cases failed to show any but temporary improvement, and 12 cases apparently were not influenced in any way by culture milk.

**The internal parasites and parasitic diseases of sheep: Their treatment and control**, I. CLUNIES ROSS and H. McL. GORDON (*Sydney: Angus & Robertson*, 1936, pp. XX+238, pls. 46, figs. 35).—Following a brief introduction, section 1 of this work on sheep parasites of major economic importance deals with the trematodes and cestodes (pp. 1-66), section 2 with the nematodes (pp. 67-185), and section 3 with the collection and preservation of parasites and method of diagnosis in the living animal (pp. 186-208). Reference is made to the parasites of rabbits and Australian native fauna—their relationship to parasitic infection in sheep—in an appendix. A glossary of terms, a five-page list of references to the literature, and an index are included.

**The Nematelminthes of sheep**, M. CROMBÉ-LANGRAND (*Les Nématelminthes du mouton. Thesis, Univ. Paris*, 1935, pp. 104, figs. [32]).—A brief introduction to the study of the roundworms of sheep, their morphology, biology, and classification, and a report upon such parasites, their habits, importance, etc., are followed by an account of preventive and control measures.

**Tuberculosis in milk goats**, O. C. CUNNINGHAM and L. H. ADDINGTON (*Jour. Dairy Sci.*, 19 (1936), No. 7, p. 435).—In tuberculin tests made in 1931 of a herd of milk goats kept by the New Mexico Experiment Station for breeding purposes, two reacted and were removed from the herd. Both of these on post mortem showed pronounced tubercular lesions. Since 1931 five more goats have been removed from the herd as a result of applying the intradermal tuberculin test. One of these on post mortem showed pronounced tubercular lesions and three others minor lesions that may have been tubercular.

The authors consider it highly desirable that goats kept for the production of milk for human consumption be tested for tuberculosis the same as are dairy cattle.

**The importance of the dilution fluid when testing with mouse the virulence and vitality of the swine-erysipelas bacillus**, P. VIRIDÉN (*Skand. Vet. Tidsskr.*, 26 (1936), No. 8, pp. 509-514; *Eng. abs.*, pp. 513, 514).—The author has

observed in diluting bouillon cultures of the swine erysipelas bacillus with a physiological sodium chloride solution that the virulence of the culture diminishes more rapidly than if the dilution medium consists of bouillon with the pH value 7.6, or if such a bouillon is diluted with physiological sodium chloride solution in the proportion of 1 part bouillon plus 4 parts of sodium chloride solution. In the course of many experiments it was found that the swine erysipelas bacillus in the bouillon culture often succumbed on dilution with sodium chloride solution, but that it did not on dilution with bouillon or with bouillon diluted in the manner above described.

**Contribution to the study of *Stephanurus dentatus* Diesing 1839, the etiological agent of stephanurosis of swine** [trans. title], C. PINTO (*Campo [Rio de Janeiro]*, 6 (1935), No. 11, pp. 27-30, figs. 3).—This account of the kidney worm of swine is accompanied by a list of 40 references to the literature.

**Meningoencephalomyelitis of the horse: Enzootic encephalitis, infectious encephalomyelitis, Borna disease** [trans. title], L. PANISSET (*Rev. Gén. Méd. Vét.*, 45 (1936), Nos. 532, pp. 193-207; 533, pp. 257-277, figs. 8).—A review of the present knowledge of this disease of the horse in its several forms is presented with a seven-page list of references to the literature.

**Studies on so-called cornstalk disease in horses.—IV, Toxic encephalitis or non-virus encephalitis**, R. GRAHAM and B. HARRIS (*Vet. Med.*, 31 (1936), No. 8, pp. 340-346, figs. 6; *Ger., Fr. abs.*, p. 345).—Reporting further (E. S. R., 73, pp. 393, 543; 75, pp. 258, 692) reference is made to one natural case of acute equine cornstalk disease in which encephalomalacia was encountered, *Pasteurella* micro-organisms being isolated from the brain tissue suspension as well as from liquid cultures of the brain tissue suspension through animal inoculation. Rabbits, guinea pigs, and pigeons received the tissue and culture inoculum, while the cultures isolated were successfully passed through rabbits, guinea pigs, and pigeons. Direct cultures of the horse brain tissue suspension on solid medium (plain agar plates) proved negative to *Pasteurella* micro-organisms upon animal inoculation.

In one peracute natural case of cornstalk disease showing encephalomalacia. *Pasteurella* micro-organisms were isolated directly from the heart blood. Animal inoculation of the liquid culture of the blood yielded *Pasteurella* micro-organisms in 20 percent of the animals inoculated.

"A composite spleen, thymus, heart, and lung suspension upon injection into rabbits, guinea pigs, and pigeons did not yield *Pasteurella* micro-organisms, while liquid cultures of the lungs, spleen, thymus, and pericardial fluid upon animal inoculation proved negative to *Pasteurella* micro-organisms. From the same animal liquid cultures of the peritoneal fluid, spinal fluid, and brain yielded *Pasteurella* micro-organisms. Intracerebral inoculation of the brain tissue suspension of this animal yielded *Pasteurella* micro-organisms from only 1 guinea pig, though a total of 12 received the inoculum with a 66% percent mortality."

**True equine piroplasmosis** [trans. title], P. ROSSI (*Rev. Microbiol. Appl.*, 2 (1936), No. 4, pp. 173-188).—This is a report of clinical observations and of hematological and therapeutic studies, presented with a list of 35 references.

**The etiology of helminth aneurisms and strongylosis of equines** [trans. title], C. PINTO and C. PROENÇA (*Campo [Rio de Janeiro]*, 7 (1936), No. 79, pp. 53-56, figs. 7; *Eng. abs.*, p. 56).—Helminths found in affected horses in Brazil include *Strongylus edentatus*, *S. vulgaris*, *S. equinus*, and *Trichonema goldi* (recorded for the first time from Brazil).

**Diseases of fur bearing animals**, A. C. SECORD (*Vet. Med.*, 31 (1936), No. 12, pp. 532-549, figs. 5).—The more important diseases and parasites of fur-bearing animals are considered.

[Contributions on diseases of poultry] (*Md. Agr. Soc., Farm Bur. Fed., Rpt.*, 20 (1935), pp. 378, 379, 380-400).—Contributions on diseases of poultry include the following: Economic Aspects of Mortality in Poultry, by C. R. Davis (pp. 378, 379); Diet and Disease in the Domestic Fowl, by H. Bunyea (pp. 380-385); Breeding and Disease in the Domesticated Fowl, by G. D. Quigley (pp. 385-389); and History of Diseases in the Domestic Fowl, by R. H. Waite (pp. 389-400).

Diseases of poultry, J. REIS, P. NORREGA, and A. S. REIS (*Tratado de doenças das aves. São Paulo, Brazil: Inst. Biol.*, 1936, pp. [8]+468+[1], pls. 4, figs. [362]).—The diseases and parasites of poultry are dealt with according to their etiology as follows: Filtrable viruses (pp. 1-91), bacteria (pp. 92-207), fungi (pp. 208-233), protozoa (pp. 234-311), helminths (pp. 312-352), arthropods (pp. 353-385), nutrition (pp. 386-407), and organic alterations (pp. 408-438). A list of references to the literature accompanies the account of each disease.

Occurrence of diseases in poultry, S. WALL (*Skand. Vet. Tidskr.*, 26 (1936), No. 7, pp. 477-497; *Eng. abs.*, pp. 495-497).—The occurrence of diseases of poultry in Sweden, based upon examinations of 4,419 fowl from 1925 to 1935, is reported upon.

A *Pentatrichomonas* associated with certain cases of enterohepatitis or "blackhead" of poultry, E. A. ALLEN (*Amer. Micros. Soc. Trans.*, 55 (1936), No. 3, pp. 315-322, figs. 8).—A description is given of a trichomonad of the genus *Pentatrichomonas* which has been observed during a period of 6 yr. in turkeys, chickens, and guinea fowls in cases that showed pathological changes closely resembling those of blackhead and in cultures made from such cases. This flagellate was grown in cultures isolated from the ceca of infected birds.

Following the feeding of cultures of the *Pentatrichomonas*, isolated from the ceca of infected poult, to turkeys, the birds developed lesions in the liver, and two turkeys, which died, had typical blackhead lesions in the ceca. A saturated solution of thymol added to iodine-eosin caused the flagella of the organisms to spread out, so that the counting of flagella was greatly facilitated. Quinamil, 1:10,000, reduced bacterial growth in the cultures.

"The evidence presented in this study indicates that various contentions that have appeared in the literature in regard to the etiology of 'blackhead' may have justification, in that it is probable that each of two species of flagellates, *H[istomonas] meleagridis* and a species of *Pentatrichomonas*, may produce similar lesions in the liver and ceca of poultry."

A list is given of 11 references to the literature.

Fowl cholera: *Pasteurella aviseptica*—behaviour and immunization, comparison with *P. suisepctica*, Z. MOROS and A. HOSNY MAHMOUD (*Vet. Jour.*, 92 (1936), No. 9, pp. 336-339).—The authors have found *P. aviseptica* and *P. suisepctica* to be morphologically and culturally indistinguishable. *P. aviseptica* is highly pathogenic to fowls and practically nonvirulent to guinea pigs on subcutaneous inoculation, while *P. suisepctica* is not pathogenic to fowls and is virulent to guinea pigs. Formalin or carbolic acid on addition to *P. aviseptica* broth cultures does not interfere with vaccine, while heating seems to interfere with the antigenic properties.

*Coryza* of fowls, G. KERNOHAN (*Nulaid News*, 14 (1936), No. 6, pp. 6, 7).—A discussion of the respiratory affections of the fowl.

The transmission of fowl-pox, A. L. BRODY ([*New York*] *Cornell Sta. Mem.* 195 (1936), pp. 37, pls. 3).—Following a brief consideration of the methods by which fowl pox is spread, experiments on the transmission of the disease by contact and by intermediate hosts are reported upon at length, the details being

given in tables covering 15 pages. The following methods of spread are considered to have been proved:

"Direct contact between diseased and healthy birds is one certain method by which fowl pox is spread within a flock. By contact the virus may spread not only to the epidermis of the head but also to the mucous membrane lining the oral and associated cavities. Non-blood-sucking flies of the family Calliphoridae probably do not transmit fowl pox. This conclusion is drawn from observations recorded in the foregoing pages and from unrecorded observations. *Aedes stimulans* may transmit pox by intermittent feeding. This insect may also harbor viable virus in or on its body for at least 2 days following the infective meal. *A. aegypti* can definitely transmit the disease more than once during its life. Mosquitoes which had been able to transmit the disease within 1 hr. after their infective meal were still able to transmit it from 39 to 41 days later. The inoculation of the bodies of mites (*Liponyssus silviarum*) 4 days after their last association with a diseased bird, produced pox on a susceptible bird. Adult mites when fed on a healthy bird 4 and 11 days after their last association with a diseased bird did not cause pox. Mosquitoes can best transmit the disease if they feed on pox lesions which are [from] 5 to 17 days old. (This conclusion is based in part on work with *Aedes vexans* and *A. aegypti* not reported in this paper.) The virus remains viable on inanimate objects for at least 42 days. In these experiments the virus could not be demonstrated on inanimate objects 61 days after contamination.

"The virus may be found in or on any part of the body of an infected mosquito during the first 3 days of the incubation period. By the fifth day at least the virus localizes in or on the proboscis and the head. The virus can still be found in or on the proboscis or the head, or both, for at least 15 days even when the insect has fed on three birds during that period."

There is said to be definite evidence that the fowl pox may arise at previously uninjured areas of the comb, although the greater number of lesions will arise at injured areas.

A list of 20 references to the literature is included.

**Observations on fowl paralysis (lymphomatosis)**, T. DALLING and G. H. WARRECK (*Vet. Jour.*, 92 (1936), No. 9, pp. 310-321).—The authors' investigations have led to the conclusion that lesions of lymphomatosis may be found in practically all tissues, including those of the nervous system, and that they may occur only in the nervous tissues or in other tissues or in both in the same bird. "Intestinal parasitic infestation plays no essential part in the causation of lymphomatosis in fowls. Clinical and histological evidence of lymphomatosis may be found in fowls at ages varying from 2 to over 38 mo. In the older affected birds there is evidence that the condition did not occur at an earlier age. There is some evidence that the injection of tissues from affected birds into healthy normal stock may play a part in transmitting lymphomatosis. Much seems to depend on the type of bird injected; some strains appear to be more readily susceptible than others. In some birds the injection of tissues from healthy birds seems to be followed by the occurrence of lymphomatosis. There is no evidence that lymphomatosis is transmitted by contact of potentially affected chicks or affected adults with healthy young chicks.

"Breeding experiments carried out in 1934 lead us to conclude that incubation and rearing play no part in the causation of lymphomatosis, for all hatches were treated similarly and the incidence in them did not differ materially."

**Epidemic tremors (trembling chick disease)**, C. A. BOTTOFF, A. E. TEPPER, C. L. MARTIN, T. B. CHARLES, and F. D. REED (*New Hampshire Sta. Circ.* 51

(1936), pp. 8).—This contribution, following a brief history of the disease first described by Jones in 1932 (E. S. R., 69, p. 112) and again in 1934 (E. S. R., 71, p. 702), reports upon transmission experiments, breeding and management studies, and the clinical history of epidemic tremors. This is an affection of the nervous system of poultry that results in a distinct and rapid tremor of the head and neck and in some cases the tail, and in a majority of which there is an ataxia, with a mortality running from 0 to 65 percent.

The transmission studies conducted, which included the placing of affected and nonaffected chicks together and intracranial inoculations of brain suspensions from affected chicks, failed to indicate how the disease is spread. The results of the breeding studies indicate that the disease is not hereditary. It occurred under four different types of brooding systems where normal brooding conditions were maintained; it also occurred in chicks fed all types of feed of varying protein level. Variations in incubation or hatching temperatures were not found to be a cause under the conditions observed. The affected birds studied showed no significant difference in body temperatures or blood counts. Attempts at treatment proved to be valueless.

**Contribution to a study of pullorum disease of the fowl, M. FERREOL** (*Contribution à l'étude de la diarrhée blanche bacillaire des poussins. Thèse Inaug., Univ. Zurich, 1935, pp. 79, pl. 1, figs. 2*).—This contribution reports upon the clinical symptoms, pathology, epidemiology, occurrence in Switzerland, economic importance, and organization of control work against pullorum disease, presented with a list of 69 references to the literature.

The pullorum-gallinarum group in comparative bacteriological tests, G. PACHECO and C. RODRIGUES (*Mem. Inst. Oswaldo Cruz, 31 (1936), No. 3, pp. 591-654, pls. 8; Eng. trans., pp. 655-705*).—In the course of the work here reported 38 strains of the *Salmonella pullorum*-*S. gallinarum* group of micro-organisms from Europe, North America, and Brazil were investigated to determine the fixity of their properties and the possibility of transforming one strain into another. Five types were recognized, namely, (1) gasogenic pullorum, (2) nongasogenic pullorum, (3) intermedius, (4) gasogenic gallinarum, and (5) nongasogenic gallinarum. A table which summarizes the more important characteristics of the five types, the first two and the last of which have been well known and recognized by specialists, the third was recognized by the author in 1935, and the fourth by Beck and R. Eber<sup>1</sup> in 1927, is included. The changes produced on neutral red, H<sub>2</sub>S production, fermentation of glycerol, isodulcitol, xylitol, dulcitol, sorbitol, and maltose, activity upon Seignette salt, gas production, and appearance of the colonies are among the characteristics on which the distinction of these five types is founded.

"The gasogenic gallinarum type, on account of its action on sorbitol and xylitol, and also on Jordan's medium, must be rather considered as a gasogenic intermedius type. Other biological characteristics, such as activity upon milk, milk whey, dextrin, etc., accepted by several specialists, appeared as of no practical value to the distinction of the different types of our strains. The strains kept their properties invariable during all the time of our investigations. The hypothesis of a possible transformation of one type into another has not been confirmed in any of the studied strains, and this justifies the idea of independence of each one of the accepted types. Some discrepancies in fermentation of maltose, as found by several authors in micro-organisms of this group, have been not confirmed in this paper. In blood horse serum a factor capable of transforming maltose was found making it fermentative. This substance is thermostable and resistant to some antidiastatic substances. The sero-

<sup>1</sup> Arch. Wiss. u. Prakt. Tierheilk., 56 (1927), No. 2, pp. 121-140, figs. 3.

logical analysis of the studied strains did not allow an antigenic distinction among the different types of the bacterial group."

A six-page list of references is included.

**The present status of pullorum disease in turkeys**, W. R. HINSHAW (*Nu-laid News*, 14 (1936), No. 8, pp. 10, 11).—Data obtained at the California Experiment Station have led to the conclusion that "baby turkeys (poults) are as susceptible to pullorum disease as are baby chicks, and show the same manifestations. The chief source of infection in poults is in the hatchery where turkey eggs and chicken eggs are hatched in the same incubator. Survivors from an acute outbreak apparently have a greater ability to absorb the infection than do chickens, and consequently fewer permanent carriers remain in the flock. Prevention of pullorum disease in turkey flocks can best be accomplished by the use of separate incubators for hatching turkey eggs and by avoiding all contact with chicks, either in the hatchery or in the brooder. In the light of our present knowledge, a general testing program for turkeys is probably not justifiable. Flocks that have accidentally become infected should be tested, however, if they are to be used for the production of hatching eggs."

**Ectoparasites and bird diseases**, C. M. HERMAN (*Bird-Banding*, 7 (1936), No. 4, pp. 163-166).—The relation of ectoparasites to the transmission of avian diseases is reviewed.

**Experiments in the treatment of poultry parasites in Puerto Rico**, W. H. WRIGHT (*Puerto Rico Sta. Agr. Notes* No. 73 (1936), pp. 7).—Observations of the internal parasites of poultry from January 6 to April 2, 1936, and the results of the administration of anthelmintics for their control, conducted by the U. S. D. A. Bureau of Animal Industry and the station, are reported upon.

Seven species of nematodes, namely, *Capillaria annulata*, *Tetrameres americana*, *Cheilospirura hamulosa*, *Strongyloides avium*, *Ascaridia galli*, *Capillaria retusa*, and *Heterakis gallinac*; five species of tapeworms, including *Davainca proglottina*, *Amoebotaenia sphenoides*, *Hymenolepis cantuniana*, *Railletina tetragona*, and *Railletina* sp.; and a trematode (*Postharmostomum* sp.) were found in island poultry. Gentian violet, azaminc, brilliant green, and mercurochrome (220 soluble) showed more or less promise for the removal of certain species of tapeworms from poultry. Gentian violet in repeated treatments also proved of value for the control of *S. avium*.

**Effects of sulphur on coccidiosis in chickens**, C. A. HERRICK and C. E. HOLMES (*Vet. Med.*, 31 (1936), No. 9, pp. 390, 391).—In work at the Wisconsin Experiment Station fowls of sulfur added to the dry mash and hopper fed prior to infection with coccidia has been found to be effective not only in reducing but also in preventing the effects of coccidia on chickens under experimental conditions. When fed for only 2 days before infection there was little if any effect of the sulfur on the coccidia, but when the sulfur was administered for 4 days before infection was established its effect was marked. The mortality was 42, 22, and 19 percent, respectively, for the controls and those receiving 10 and 20 percent sulfur. When 20 percent sulfur was fed for a period of 6 days there was a reduction in the severity of the lesions and no mortality from an infection of coccidiosis which was fatal to 70 percent of those that were not given sulfur. The feeding of 10 percent sulfur, although preventing visible lesions in one-third of those treated, did not prevent all mortality.

It is concluded that much work remains to be done before the method can be recommended as a practical means of controlling coccidiosis. There was no evidence that the administration of sulfur has any curative effect on coccidiosis in poultry after the infection has become established.

**Disinfection of poultry yards**, E. C. McCULLOCH (*Vet. Med.*, 31 (1936), No. 9, pp. 386-389).—This discussion, which is based upon the work previously noted (*E. S. R.*, 75, p. 699) and a review of the literature, is presented with a list of 20 references.

**Ovarian cyst in a parrakeet**, A. J. DURANT (*Vet. Med.*, 32 (1937), No. 2, p. 75, fig. 1).—This is a case report from the Missouri Experiment Station.

## AGRICULTURAL ENGINEERING

**[Agricultural engineering investigations by the California Station]** (*California Sta. [Bien.] Rpt. 1935-36*, pp. 3-8, 10, 11, 127-132).—Progress results are briefly presented of investigations on soil and water conservation, drainage, lowering of peat lands, irrigation by portable sprinklers, efficiency of irrigation pumping plants, ethylene treatment and dehydration of walnuts, machinery for lima beans and sugar beets, blowers for frost protection, and air cleaner performance.

**[Agricultural engineering investigations by the Cornell Station]** (*New York] Cornell Sta. Rpt. 1936*, pp. 73, 135).—The progress results are briefly presented of investigations on milk-cooling equipment, by H. W. Riley, B. A. Jennings, and H. J. Brueckner; milk-house construction and equipment, by Jennings, Riley, M. W. Nixon, and Brueckner; and air-conditioning in poultry houses, by G. O. Hall and F. L. Fairbanks.

**Ground water in Gila and San Simon Valleys, Graham County, Arizona** (*U. S. Dept. Int., 1936*, P. N. 128150, pp. 2).—This mimeographed leaflet gives a brief account of the ground water resources of these two valleys.

**Improving drain tile resistance to alkali conditions**, D. G. MILLER (*Agr. Engin.*, 17 (1936), No. 12, pp. 513-515, 544, figs. 3).—This paper is based on results of observations of experimental concrete specimens subjected to artificial sulfate solutions in the laboratory and to the behavior of specimens installed under natural field exposure conditions in Minnesota and North Dakota and in Medicine Lake, S. Dak. The salt content of the lake ordinarily averages about 5 percent, with an extreme around 12 percent during 1934 and 1935. About two-thirds of the salts are magnesium sulfate and one-fourth sodium sulfate. For this work over 60,000 2- by 4-in. cement-concrete and cement-mortar cylinders, 4,000 specially made concrete drain tile, and numerous miscellaneous specimens were used. The studies are cooperative between the Minnesota Experiment Station, the Minnesota State Department of Conservation, and the U. S. D. A. Bureau of Agricultural Engineering.

It was found that under identical exposure conditions concrete made of a highly resistant portland cement may last 10 times as long as that made of a cement of low resistance. Resistance of concrete is markedly increased by curing in water vapor at temperatures of from 212° to 350° F., almost to the point of immunity for the most favorable temperatures and curing periods. Resistance is not increased, however, by raising the curing temperatures until 212° is reached, except in connection with certain admixtures.

Apparently about equal resistance is secured by curing for the time periods and temperatures as follows: 212° for 8 days, 230° for 4 days, 260° for 2 days, 285° for 1 day, 315° for 12 hr., and 350° for 6 hr.

Calcium chloride used as admixture in concrete cured in water vapor at temperatures between 100° and 155° appreciably increases resistance, but check tests are too limited as yet to justify specific recommendations.

It is pointed out that, regardless of all other factors, care should be observed in all particulars to obtain the highest practicable 28-day strength with any given cement and any predetermined condition of curing. Strength, although

fallible for comparing different concretes, has much value as an index of the permeability and sulfate resistance of the products made of the same cement and by the same methods of manufacture. This is particularly true where rich mixes are used as is the case in the manufacture of high quality drain tile.

**Soil defense in the Piedmont, E. M. ROWALT** (*U. S. Dept. Agr., Farmers' Bul. 1767 (1937), pp. IV+63, figs. 31*).—This deals in a popular manner with erosion of the soil and measures of defense which have proved successful in controlling erosion in that part of the Piedmont country lying in the States of Virginia, Georgia, Alabama, and the Carolinas. Control measures involve terracing, contour tillage, strip cropping, rotation with close-growing crops, and contour furrowing in pastures.

**Cost of terracing with power equipment, D. G. CARTER and W. C. HULBERT** (*Agr. Engin., 17 (1936), No. 12, pp. 511, 512, fig. 1*).—In a brief contribution from the Arkansas Experiment Station cost data are reported based upon an analysis of 240 terracing jobs in 7 Arkansas counties where 40-hp. Diesel tractors operating 10-ft. blade terracers are in operation.

Soil improvement associations were organized in each of these counties to handle the equipment. Work included typical terrace construction, usually "seven-cut" or three and one-half rounds of the machine, and built according to the usual recommendations for vertical interval, grade, width, and cross section. The associations are required to make a uniform charge of \$3 per hour to the landowner for the use of the equipment and the operating crew. This charge is made for the time the tractor is in actual operation, but includes the service of surveying the field and laying out the terrace lines. The 240 jobs required 2,216.35 hr., the acres terraced amounted to 6,670, and the net average cost per acre was 99.7 ct. From data on lineal distances the costs are indicated as 33.8 ct. per 100 ft. of terrace. For the jobs analyzed the operating costs amounted to \$4,312.12, or 64.6 ct. per acre, or 21.9 ct. per 100 lineal feet of terrace. The hourly operating cost totaled \$1.95.

**Thermal expansion of typical American rocks, J. H. GRIFFITH** (*Iowa Engin. Expt. Sta. Bul. 128 (1936), pp. 36, figs. 21*).—This bulletin reports research the purpose of which was to determine the coefficients of expansion of typical American rocks of the type used for building purposes through the moderate ranges of temperature usually encountered in building practice. Approximately 100 representative American rocks of varying chemical constitutions and diversified geographical locations were included in the study.

The expansions appear to be dependent upon the amounts of free silica in the rocks; the rocks having a maximum of free silica expand the most, and those with a maximum of combined silica expand the least.

There was a lack of conclusive evidence of the presence of inversions as indicated by inflections in the thermal expansion curves. Discontinuities in slopes of curves for natural silicates appear to arise from several structural discontinuities such as minute cracks or slip planes in specimens. The inversions appear to occur through a range of temperatures rather than abruptly at the theoretical 220° C. expected.

An appendix includes thermal expansion curves.

**Strength, absorption, and resistance to weathering of common and face brick manufactured in Virginia, J. W. WHITEMORE and P. S. DEAR** (*Va. Engin. Expt. Sta. Bul. 26 (1936), pp. 32, figs. 2*).—The purpose of this investigation was to assemble authoritative information regarding the merits of Virginia manufactured bricks and their classification according to the latest tentative specification for the American Society of Testing Materials.

Of the bricks submitted as salable by the manufacturers, 95.5 percent represent bricks that are hard and well-fired, 95.5 percent represent bricks that are

resistant to weathering, 73.3 percent are suitable for use where exposed to severe weathering such as severe frost action, and 17.7 percent additional are suitable where exposed to ordinary weathering conditions. On the basis of strength alone, all of the bricks submitted pass the minimum requirements of the A. S. T. M. specifications.

The influence of the character of the petroleum on the initial toxicity to wood destroying fungi of creosote-petroleum mixtures, H. SCHMITZ (*Amer. Wood-Preservers' Assoc. Proc.*, 32 (1936), pp. 145-166, figs. 9).—Studies conducted at the Minnesota Experiment Station are reported.

The initial toxicity of creosote-petroleum mixtures appears to be influenced not only by the initial toxicity of creosotes entering such mixtures but also by the character of the petroleum in the mixture. Mixtures of petroleum of high specific gravity appear to be less toxic than mixtures of petroleum of lower specific gravity. Before this relationship can be accepted as established it will be necessary to make a more extended study of the subject.

Public Roads [January and February 1937], (*U. S. Dept. Agr., Public Roads*, 17 (1937), Nos. 11, pp. [2]+249-280+[2], figs. 19; 12, pp. [2]+281-303+[1], figs. 27).—These numbers of this periodical contain data on the status of various highway projects as of December 31, 1936, and January 31, 1937. No. 11 also contains an article entitled Experimental Bituminous Treatment of Sandy-Soil Roads, by P. F. Critz and H. L. Sligh (pp. 249-278), and No. 12 an article entitled Weed Control and Eradication on Roadsides, by O. K. Normann (pp. 281-300).

Alcohol and alcohol-gasoline blends as fuels for automobile engines.—VI, Studies on the use of alcohol-gasoline mixtures as fuels for a high compression eight-cylinder automobile engine, A. L. TEODORO and E. K. ONGSANBOY (*Philippine Agr.*, 25 (1936), No. 6, pp. 479-492, figs. 11).—This is the sixth contribution on the subject from the University of the Philippines (*E. S. R.*, 75, p. 405).

Studies were made to compare the performance curves of gasoline with those of alcohol-gasoline mixtures as fuels in an eight-cylinder automobile engine using high-compression heads. Two sets of cylinder heads were used, one set giving a compression ratio of 6.3 and the other a compression ratio of 7.5.

Using ordinary gasoline this engine when tested on the bench at a compression ratio of 7.5 could not develop more than one-half of the maximum power that could be developed at a compression ratio of 6.3. With four passengers as a carload and at a speed of from 20 to 35 miles per hour, higher mileage could be obtained with the use of high-compression heads than with low-compression heads. Detonation was very much in evidence when accelerating, when rounding curves, and when climbing hills. Unsteadiness in operation and loss of power were observed at speeds greater than 35 miles per hour.

When using a mixture of 90 percent gasoline and 10 percent dehydrated alcohol, detonation was so heavy at full load that it was not possible to obtain constant operation for over 10 sec. at any of the desired speeds. At three-fourths load using this mixture and at full load using a mixture of 80 percent gasoline and 20 percent dehydrated alcohol detonation was evident, though the engine could maintain constant load at the desired speed for about 30 min. No detonation was heard in any other tests.

The specific fuel consumption and the mileage obtained with mixtures containing from 40 to 60 percent alcohol when using high-compression heads were nearly the same as those obtained with gasoline when using lower-compression heads. The mileage obtained with the mixtures containing from 10 to 40 percent alcohol was greater than those with gasoline. The mileage gradually decreased as the percentage of alcohol increased from 10 to 40 percent. The

decrease in mileage was from about 1.8 to 4.5 percent per every 10 percent of alcohol added in the mixture with fuels containing from 40 to 95 percent alcohol.

The maximum power developed at the highest speed on full load with high-compression ratio when using the mixtures was more than 10 percent greater than the maximum power that could be developed at the same load with gasoline when using a compression of 6.3.

**Tractor engine lubrication under low temperature conditions**, E. A. HARDY (*Agr. Engin.*, 17 (1936), No. 11, pp. 465, 466, 470, fig. 1).—The results of experiments and observations of tractor engine lubrication under the low temperature conditions prevailing in western Canada during the winter are briefly presented as a contribution from the University of Saskatchewan.

It has been found that the tractor engine must be given special consideration if adequate lubrication is to be had. The engine must be warmed up quickly and maintained at a reasonably high operating temperature. The oil must be clean and of a grade which will flow freely in forming a mist to lubricate the working parts of the engine. The use of top lubrication or oil in the gasoline to protect the piston rings and cylinders during the warming-up period is imperative. Finally the engine must be in good mechanical condition and protected from the extreme cold when operated in zero or subzero weather.

**Nebraska tractor tests, 1920-1936** (*Nebraska Sta. Bul.* 304 (1937), pp. 38, fig. 1).—This summarizes the results of 87 tractor tests and includes data on all tractors reported on the market on January 1, 1937 (*E. S. R.*, 74, p. 706).

**Farm electrification statistics, September 30, 1936** (*C. R. E. A. News Letter* [Chicago], No. 14, (1936), pp. 2, 3).—Tabular data are presented showing, among other things, the farms in the United States having electric service on December 31, 1935, and on September 30, 1936.

**New developments in fertilizer placement research**, G. A. CUMINGS (*Agr. Engin.*, 17 (1936), No. 11, pp. 461-464, figs. 2).—In this brief contribution from the U. S. D. A. Bureau of Agricultural Engineering, the progress results are briefly summarized of the fertilizer placement phase of the work of the National Joint Committee on Fertilizer Application.

The results of the 1935 experiments in general indicate that fertilizer is of the greatest benefit to the crop when applied in a band at each side of the row. A placement approximately 2 in. to the side of the seed or plant and about 3 in. below the surface of the ground was the superior treatment in most cases. The most effective location of the fertilizer band at the side of the row differed somewhat with the crop, soil, and weather conditions, and the amount of fertilizer. Fertilizer placed directly under the seed or plant, either in a band or mixed with the soil, in most cases caused early injurious effects which were reflected in the yields. Fertilizer applied broadcast in a limited number of experiments was in all instances decidedly inferior to comparable placements at the side of the row.

The results of experiments with narrow row crops are also presented, and information is given on the development of equipment for advantageous placement of fertilizer.

**Harvesting with combines**, W. M. HURST and W. R. HUMPHRIES (*U. S. Dept. Agr., Farmers' Bul.* 1761 (1936), pp. [2]+37, figs. 13).—Practical information is given on the development of the combine, the function of its various parts, its attachments, operation, and care. Information also is given on crop characteristics as they relate to combining problems.

**New developments in sugar beet machinery**, E. M. MERVINE and S. W. McBERNEY (*Agr. Engin.*, 17 (1936), No. 11, pp. 467-470, figs. 5).—Recent developments in sugar beet machinery resulting from cooperative studies conducted by

the U. S. D. A. Bureau of Agricultural Engineering and the State agricultural experiment stations in the sugar beet growing States are briefly summarized.

**A new buhr type feed mill**, F. W. DUFFEE (*C. R. E. A. News Letter [Chicago]*, No. 14 (1936), pp. 24-26, fig. 1).—In a brief contribution from the Wisconsin Experiment Station a 6-in. buhr mill with the main part of the mill a one-piece casting, giving rigidity and simple construction, is described as developed at the station. Service tests have indicated that a half-hour's grinding a day with a 2-hp. motor will take care of the grinding for 20 cows. The mill grinds slowly but very cheaply, and can be operated with a motor varying in size from 0.75 to 3 hp. Tabular data on its operation are briefly presented.

**Energy consumption of large churns**, J. B. RODGERS (*Agr. Engin.*, 17 (1936), No. 12, pp. 516, 517, fig. 1).—Data on the electric power requirements of creamery equipment are reported by the Idaho Experiment Station.

**Orchard blowers for frost protection**, B. D. MOSES (*C. R. E. A. News Letter [Chicago]*, No. 14 (1936), pp. 9, 10, fig. 1).—The results of service experiments on the use of blowers for the protection of orchards against frost are briefly reported in a contribution from the California Experiment Station.

**Corn drying investigations of the Oregon Experiment Station**, F. E. PRICE and I. BRANTON (*C. R. E. A. News Letter [Chicago]*, No. 14 (1936), pp. 7-9, figs. 4).—Experiments briefly described on the dehydration of ear corn proved that the problem is a simple one of forcing heated air through kilns of ear corn of a depth of from 2 to 3 ft. For drying corn to be used for feeding it was found that the maximum temperature of the air from the furnace may be 175° F.

Satisfactory drying of ear corn was accomplished by using from 75 to 100 cu. ft. of air per minute per square foot of kiln area. It was found possible to recirculate from 50 to 75 percent of the air in the drying system, saving from 45 to 60 percent of the fuel required with no decrease in the speed of drying.

The drier developed for the experiments was a vertical column, continuous process drier. Heated air was forced through two moving vertical columns of corn from a duct between the two columns. The drier was so designed that the thickness of the corn column through which the heated air was passed could be changed to determine the column thickness that would give best results.

Increasing the drier temperature increased the output of the drier per unit area of column space. For that reason it is desirable to operate at as high a temperature as possible without injury to the corn. Shelled corn was dried in less than 1 hr. in the continuous process drier at 175°. In drying corn at temperatures of from 120° to 180° it is advisable to recirculate a considerable portion of the air in the drying system.

**The Wisconsin seed corn drier**, F. W. DUFFEE (*C. R. E. A. News Letter [Chicago]*, No. 14 (1936), pp. 5-7, figs. 2).—In a brief contribution from the Wisconsin Experiment Station the bin method of drying seed corn developed by the station is described and illustrated, it being pointed out that this method is practical only for use by those who make a business of producing seed corn.

The equipment necessary is a furnace, a multivane blower, a series of bins, necessary power, and a suitable building. The furnace heats the air to around 100° F. The fan blows the air through the bins filled with corn.

The most satisfactory arrangement of bins has been found to be two rows of bins with an alley 3 ft. wide between them. This alley receives the heated air from the fan and connects with the top and bottom of each bin. In this way the heated air can be conveyed to any bin as desired, and by means of dampers the direction of the air in any bin can be controlled.

Seventy-five percent of the air which passes through the corn is brought back to the fan or furnace for recirculating. This cuts the fuel bill up to 50 percent. The heated air is forced through the corn at a rate that does not allow it to make full use of its drying capacity.

A false slatted bottom made out of 1- by 4-in. lumber placed edgewise and about 1 in. apart is placed in each bin about 1 ft. above the floor. This supports the corn and permits the air to flow underneath. Each bin has two dampers, one at the top and one at the bottom, connecting with the alley, and these are open when corn is being dried. On the outside is a door used for loading and unloading the corn.

**Chili pepper dehydrator**, L. E. HOLMES (*C. R. E. A. News Letter [Chicago]*, No. 14 (1936), pp. 20-22, figs. 6).—This equipment as developed in southern California is described and illustrated, with some results of service tests.

**Electric pig brooders**, J. R. TAVERNETTI (*C. R. E. A. News Letter [Chicago]*, No. 14 (1936), pp. 10, 11, figs. 4).—In a brief contribution from the California Experiment Station experiments with electric pig brooders are reported.

Two of the brooders were of the radiant or light type, and two were of the underheat type. The light types consisted of 150-w bulbs in 12-in. white enameled reflectors placed over a hole in the top of a triangular-shaped hover 12 in. high and 3.5 ft. on the sides. The underheat type consisted of the same size and shape of hover containing an enclosed galvanized iron box 2 ft. square and 2 in. deep, in which were mounted open heating coils having a connected load of 100 w. The brooders were placed in a corner of the regular farrowing pens from which the guard rails had been removed. A total of 10 sows farrowed in the pens containing the brooders—5 in the two with the light type and 5 in the two with the underheat type.

No difference was observed with the two different types of brooders, but 83.6 percent of pigs farrowed in 1936 were raised to 10 days of age with brooders while only 81.7 percent were raised without brooders.

**Air conditioned poultry brooder houses**, J. E. NICHOLAS and E. W. CALLENBACH (*Agr. Engin.*, 17 (1936), No. 12, pp. 518-521, figs. 6).—Studies conducted at the Pennsylvania Experiment Station are reported which showed that insulation plays an integral part in maintaining desired temperatures and humidities. Four standard 12- by 16-ft. Penn State brooder houses were used, referred to as houses 19, 20, 21, and 22. Curtain and window openings were eliminated. Double doors were used, outside doors being the original standard 3- by 6.5-ft. batten doors. The 6-in. ceiling spaces and the 4-in. wall spaces in houses 19 and 20 were filled with insulating material (mineral wool for house 19 and processed vermiculite for house 20), held in place by  $\frac{3}{8}$ -in. wallboard. The inside doors were constructed with 4 in. of the respective insulation held in place by the wallboard. In houses 21 and 22, the walls, ceilings, and inside doors were lined with two thicknesses of 1-in. Celotex. The floors in all houses were covered with 2 in. of planer shavings.

Two of the brooder houses were operated as "hot" pens, the other two being "cold." In the former, the temperature to be maintained was 75° F., taken 2 in. above the floor at a point 28 in. from the edge of the brooder. The allowed temperature variation was to be approximately  $\pm 2.5^\circ$ . The two cold houses were to be maintained as near to 35° as the existing outside weather conditions would allow.

All equipment was operated electrically. The houses were provided with sufficient insulation and heat to permit six air changes per hour and maintain a 75° temperature differential in zero weather. Two electric heaters equipped with fans, having a heating capacity of 1,320 w each, were used in the hot

houses. One heater was placed in each cold house and set to operate when the house temperature dropped below 35°.

In the two experimental series, 125 sexed chicks were used in each house. The houses and equipment as described were used for the first series from November 27, 1935, to February 20, 1936, houses 19 and 22 being hot and 20 and 21 cold. In the second series from February 26 to May 20, 1936, houses 19 and 20 were hot, while 21 and 22 were cold.

It was impossible to hold the brooder houses at a temperature of 35° without refrigeration, even in winter brooding. There was a wide difference in relative humidity between the cold and hot houses when moisture was not supplied in the latter in the first series. The difference in relative humidities in the cold houses 19 and 20 without additional moisture was but 1 percent. In the hot houses 21 and 22, with additional moisture in the second series, the difference was 5 percent. This is probably due in part to the variation in the number of air changes in the respective houses.

**Farm and community refrigeration**, E. L. CARPENTER and M. TUCKER (*Tenn. Engin. Expt. Sta. Bul. 12* (1936), pp. 63, figs. 20).—This bulletin discusses in popular language the value, uses, designs, costs, and economical operation of refrigeration and refrigeration equipment for farms and rural communities.

## AGRICULTURAL ECONOMICS

[Investigations in agricultural economics by the California Station, 1934-36] (*California Sta. [Blen.] Rpt. 1935-36*, pp. 137-151).—Results of investigations not previously noted are reported for studies of the Gravenstein apple situation and the cost of producing honey.

[Investigations in agricultural economics and farm management by the Cornell Station, 1935-36] ([*New York*] *Cornell Sta. Rpt. 1936*, pp. 63-68).—Brief reports of results found in studies not previously noted are reported as follows: Costs and returns on 93 New York farms, 1934, and prices and yields of apple varieties, both by P. S. Williamson; 1935-36 farm management studies on 100 vineyard farms each in Schuyler and Yates Counties, by E. G. Misner; factors affecting United States imports of butter, variability in retail, wholesale, and farm prices of milk, retail and wholesale prices of butter and evaporated milk, farm prices of butterfat, etc., in the periods 1922-29 and 1930-35, and the spread between farm and retail prices of milk, 1922-35, all by L. Spencer; costs and methods of operation of commercial trucks in transporting fruits and vegetables to market in nine States, by M. P. Rasmussen, N. Fogelberg, and H. W. Mumford, Jr. (U. S. Farm Credit Administration); the public markets situation in south-central New York, by A. T. M. Lee and Rasmussen; land utilization and classification in six counties, by T. E. La Mont; costs of store credit, by O. H. Maughan; and sources and costs of farm credit, by G. W. Hedlund.

[Investigations in agricultural economics by the University College of Wales] (*In Survey of the work of the agricultural departments, University College of Wales, Aberystwyth. [Aberystwyth]: Univ. Col. Wales, 1936*, pp. 61-77).—The work in agricultural economics at the college is briefly described, and some results are given of investigations of agricultural progress in Wales, population, sources of labor and use of supplies, costs of production of milk, farm earnings, and incomes of farm families.

**Graphic summary of the agricultural situation, with some related general economic factors** (*Tennessee Sta., Agr. Econ. and Rural Social. Dept. Rpt. 21* (1936), pp. IV+36, figs. 33).—In part 1, The Agricultural Depression, graphs

present data as to the national and agricultural income, per capita production of major industries, prices received and paid by farmers, farm mortgage indebtedness and interest, farm prices and freight rates in the United States, foreign production of agricultural products and other industries, demands for feeds for work stock, etc. Part 2 discusses Some General Economic Factors Affecting the Agricultural Situation.

**Agricultural outlook for Illinois, 1937** (*Illinois Sta. Circ. 464 (1936)*, pp. 32, figs. 13).—"The Illinois agricultural outlook for 1937 is intended to supply information which will enable farmers to plan more intelligently their farming and marketing operations for the coming year. The information given is based on present available knowledge concerning State, national, and worldwide agricultural and economic conditions—the present and probable future supplies of farm products and the present and probable demand for these products and of the commodities farm people buy."

**Drainage and irrigation, soil, economic, and social conditions, Delta area, Utah.**—Div. 8, **Economic conditions**, W. P. THOMAS and G. T. BLANCH (*Utah Sta. Bul. 273 (1936)*, pp. 50, figs. 7).—This bulletin, the third of the series previously noted (E. S. R., 73, p. 586), deals with the economic conditions of the area. It analyzes and discusses the ability of the farmers to pay taxes, farm indebtedness, and farm expenses, and makes recommendations for farm business reorganizations. Analysis is made of the farm business in the area, using 85 farm reports for the 1929 crop year, 92 for 1930, and 111 for 1931.

During the 3 yr. studied the average farm investment of the farms surveyed was \$7,804, indebtedness \$3,357, yearly receipts \$1,461, cash operating expenses \$1,304 exclusive of \$166 for livestock purchases, and labor income—\$709.

The major steps recommended in reorganization of the agriculture of the area are "(1) taking from cultivation all large areas of land that normally do not produce sufficiently to pay the costs of cultivation; (2) transfer of irrigation water from the less productive soils to the better soils of the area; (3) establishment of larger farm units; (4) livestock production as the major enterprise of the area; [and] (5) capacity of the land to produce should be the basis for the reorganization program for the area."

**A socio-economic atlas of Oklahoma**, M. F. BURRELL (*Oklahoma Sta. Misc. Paper, 1936*, pp. VI+124, figs. 168).—Included are maps and charts showing county boundaries, cities, post offices, physiographic regions, soil types, climatological data, number of farms, use of land, crop data, values of farm land, buildings, and machinery, numbers or amounts of livestock and livestock products, tenure of farm lands, type of farming area, mineral resources, public utilities, transportation facilities, distribution of industrial plants, population, illiteracy, banking, county bonded indebtedness, and other similar data.

**Farm tenure in Iowa.**—I, **Tenancy problems and their relation to agricultural conservation**, R. SCHICKELE and C. A. NORMAN (*Iowa Sta. Bul. 354 (1937)*, pp. 161-184, figs. 12).—This bulletin summarizes the discussion with 28 County Agricultural Conservation Committees of the amounts and causes of mobility of tenants, instability of ownership and insecurity of tenants, types of leases, and the provisions as to length, compensation for unexhausted improvements, minor repairs, rent adjustments, landlord's lien, use of land, etc., and improvements in the leasing practices. The study was made in cooperation with the U. S. D. A. Bureau of Agricultural Economics, the Agricultural Adjustment Administration, and the Resettlement Administration.

**Migratory labor in California** (*San Francisco: State Relief Admin. Calif., 1936*, pp. [9]+224, [pls. 8, figs. 10]).—This study, prepared under the direction

of A. Holzschuh, includes a history of migratory labor in California, by F. Safer; the findings in a study of 775 agricultural workers on relief in California, by G. E. Kimble and R. Wilson; and case studies of four migrating families, by E. Edwards, H. White, and W. J. Plunkert.

**Drought refugee and labor migration to California** (*U. S. Dept. Labor, Bur. Labor Statis., Mo. Labor Rev., 42 (1936), No. 2, pp. 312-318; 43 (1936), No. 6, pp. 1355-1363*).—In No. 2, by P. S. Taylor and T. Vasey, tables show by months, June 16–December 15, 1935, and by State of origin the numbers of migrants "in need of manual employment" entering California, the number entering California in automobiles, the major race groups entering from selected States, and the number of Mexican migrants. Of the 53,374 migrants, 89.5 percent were white and 6.3 Mexican and 19.1 percent were returning Californians.

No. 6, by E. J. Rowell, covers the year ended June 15, 1936.

**References on the Great Lakes-Saint Lawrence waterway project**, E. E. EDWARDS and E. J. LOWE (*U. S. Dept. Agr., Library, Bibliog. Contrib. 30 (1936), pp. [5] + 185*).—This mimeographed annotated bibliography includes 5 references to bibliographies, 10 general background references, 43 references to the documents of Canada and its provinces and the United States and States, 650 references to books, pamphlets, and articles, and 211 references on the Georgian Bay, Sault Ste. Marie, and Welland Canals and lake level problems.

**Characteristics and costs of county government in Arkansas**, C. O. BRANLÉN (*Arkansas Sta. Bul. 338 (1937), pp. 91, figs 3*).—"The chief purpose of this study has been to determine the costs and bases of support of county government in relation to operating divisions and their functions, and to indicate, wherever possible, changes that might be made either for reduction in cost or improvement in services. The methods used have included the collection of information from official sources on revenues, operations, and expenditures, and the arrangement of such information to reveal, primarily, essential facts pertaining to administrative costs." The period used is the budget years of 1931 and 1932.

The duties of administrative offices and the fee system of payment of officers are described. Analysis is made of the budgets and costs, and the variations between counties and the possibilities of reducing costs are discussed.

The total average (1931 and 1932) cost of county government was \$7,667,036, of which 30.6 percent (\$1.27 per capita) was expended for constitutional offices, 30.7 percent for general county expenses, including bonds, and 38.7 percent for county roads. Of the general costs, 33 ct. per capita went for court costs other than administrative office fees, 21 ct. for pauper and other charity, 21 ct. for county bonds, 4 ct. for agricultural and home economics extension work, 3 ct. for health service, and 45 ct. was unspecified.

"It is evident that many of the costs of county government are too high in terms of the actual services performed, mainly because of the arbitrary number of officers provided in the constitution, the fee method of compensation prescribed by the general assembly, and the lack of privilege on the part of the county to manage either expenditures or personnel. . . . If worth-while county governmental reform is ever to be realized, it will be necessary to amend the constitution. The least that a constitutional amendment, for this purpose, should provide at the option of the county are the following: (1) Consolidation of county offices and rearrangement of the duties between officers, (2) management of the fiscal and personnel affairs of the county, (3) substitution of appointive for certain elective officers, particularly the tax assessor, and (4) an elective board of managers, not to exceed 15 members per county,

to take the place of the present quorum court, to have official charge of all county business, including administrative offices, special services, and the county road system."

**Reorganization of local government in New York State** (*N. Y. State Comm. Rev. Tax Laws Rpt.*, 6 (1935), pp. 695, pl. 1, figs. 35).—This sixth report of the New York State Commission for the Revision of the Tax Laws includes chapters on reorganization and the transfer of functions, the present legal framework of local government, highway construction and maintenance, public health and welfare, the control of crime, county clerk and the register, the assessment of property and collection of taxes, the cost of local government in New York, local controls over expenditures, State aid in New York, the personnel problem in New York State's local governments, municipal credit in New York State, the fee system of compensation, the village as a special problem, the attitude of county officials toward the reorganization of local government, efficiency and economy through the establishment of cooperative services, and new problems of local government, and the conclusions reached by the commission and its recommendations to the legislature.

**Some economic problems of cotton gins in Oklahoma**, R. A. BALLINGER and R. C. SOXMAN (*Oklahoma Sta. Bul.* 231 (1936), pp. 76, figs. 5).—"The purpose of this study is to examine thoroughly the operation of cotton gins as a public service business under the supervision of the State Corporation Commission of Oklahoma. The available records of the commission, particularly with respect to the number, size, and location of gins, the volume of ginnings, the operating revenues, expenses, and profits of the industry in relation to the variable factors peculiar to the business have been analyzed in order to show the importance, or lack of importance, of various factors in determining the financial success of cotton gins." The legal regulations regarding gins, the establishment of ginning rates by the Corporation Commission of Oklahoma, the importance of snapping cotton and its influence on the financial structure of gins, and the cotton buying activities of ginnerers are also discussed.

The number of gins decreased with some fluctuations from 568 in 1926-27 to 380 in 1932-33 in the eastern part of the State and increased from 331 to 391 in the western part of the State. During the period from 1929-30 to 1932-33 the average book value per gin was \$15,112 in the eastern part and \$23,707 in the western part of the State. The average number of bales received per gin was 880 and 1,472, and the average number of saws per plant 314 and 375, respectively, in the two areas. Of the gins, 52.2 percent in the eastern part of the State and 51.3 percent in the western part were owned by corporations. Of all plants, 16.6 percent were operated by partnerships, 16.5 by individuals, and 11.6 percent by cooperative associations, 95.7 percent of the cooperative associations being in the western part of the State.

Operating revenues per plant in the western part of the State were more than double those in the eastern part, but the net income per plant was several times larger in the western part. Reduction of ginning rates during the 4-yr. period reduced revenues per bale 29.6 percent in the eastern part and 22.2 percent in the western part of the State, but the decreases were more than offset by decreased expenses per bale of 37.1 and 28.4 percent, respectively, in the two areas. Since 1930-31 the net income per bale has decreased in the eastern part and increased in the western part of the State. The expense of ginning declined rather consistently as the number of bales ginned increased. From 1929-30 to 1932-33, 719 gins (22.1 percent of the total number), of which 78.7 percent were in the eastern part of the State, were operated at a loss. The gins showing a loss ginned on an average 490 bales as compared with 1,361

bales in the plants showing a profit. When analyzed on the basis of number of bales to gin there was little if any significant difference in the profits per bale in gins under different types of ownership nor in the relation of number of days gins were operated to expenses and income per bale.

Snapped cotton made up 52.5 percent of the cotton ginned during the 4 yr., 94.5 percent of the gins receiving 20 percent or less of their unginned cotton as snapped cotton being in the eastern part of the State. The larger proportion of snapped cotton increased the profits per bale in the western gins. Of the total ginnings, 63.5 percent were purchased by the ginners, of which amount 31.5 percent was purchased in seed (principally in the eastern part of the State), and 68.5 percent as lint.

**Rates for ginning and wrapping American cotton, and related data, seasons 1928-29 to 1935-36, J. W. WRIGHT and W. B. LANHAM (U. S. Dept. Agr., Bur. Agr. Econ., 1937, pp. 35, figs. 4).**—Tables and charts are included and discussed showing among other data the capacity of gins, volume of ginnings, systems of assessing charges used, and estimated average charges under each system. A table of rate conversion formulas is given.

Average charges for ginning and wrapping upland cotton declined from \$5.96 per 500-lb. bale in 1928-29 to \$4.12 in 1931-32, then rose to \$5.04 in 1934-35 and 1935-36. The charges for American-Egyptian cotton decreased from \$17.21 in 1928-29 and 1929-30 to \$11.06 in 1931-32, then increased to \$12.72 in 1935-36. The quantity of seed cotton required for a standard bale in the different sections of the Cotton Belt varied considerably. The averages in 1934-35 were hand-picked cotton 1,423 lb., snapped cotton 1,972, bollies 2,242, and sledded cotton 2,589 lb. Of the cotton gins, approximately one-half were owned by individuals and one-fourth each by partnerships and corporations.

**The distribution of American raw cotton, season 1932-33, J. W. WRIGHT and J. H. McLURE (U. S. Dept. Agr., Bur. Agr. Econ., 1937, pp. 121, figs. 34).**—Tables, charts, and maps are included and discussed showing the primary distribution from producing regions, the world distribution of American raw cotton, supply areas of domestic consuming centers, areas of supply and distribution for ports and interior markets, modes of transportation, types of bales, and seasonal movements of cotton.

Approximately 42 percent of the cotton in 1932-33 went to domestic consuming centers, the remainder being exported. Of the domestic distribution, approximately 83 percent went to mill centers in cotton-producing States. The exports were principally to Germany, Japan, Great Britain, France, and Italy. Of the domestic distribution, about 72 percent was shipped by rail, 21 percent by trucks, and 7 percent by water or combined rail and water. Of the cotton received at southern ports, 72 percent was transported by rail, 22 percent by trucks, and 6 percent by inland waterways. Of such cotton, approximately 38 percent was shipped in uncompressed square bales, 58 percent in compressed square bales, and 4 percent in round bales. Seventy percent of the cotton was shipped during the months from September to January, inclusive.

**Trends in the Canadian tobacco industry, 1920-1934, T. G. MAJOR (Canada Dept. Agr. Pub. 487 (1936), pp. 32).**—The areas in production, development of the leaf production industry, prices, costs of production, the domestic market, and export trade are discussed. The conditions in other producing countries are also described briefly.

**World wheat survey and outlook [January, May, and September, 1936], M. K. BENNETT, H. C. FARNSWORTH, and H. WORKING (Wheat Studies, Food Res. Inst. [Stanford Univ.], 12 (1936), Nos. 5, pp. [2]+183-220, figs. 8; 9, pp. [2]+313-338, figs. 5; 13 (1936), No. 1, pp. [2]+31, figs. 7).**—Data as for these three dates are reported in the respective numbers.

**World wheat utilization since 1885-86, M. K. BENNETT** (*Wheat Studies, Food Res. Inst. [Stanford Univ.], 12 (1936), No. 10, pp. [2]+339-404, figs. 13*).—This study represents a pioneer attempt to survey developments in the utilization of wheat, as distinguished from production or supplies of wheat, in a specially defined "world" during the past 50 yr. The course of world wheat utilization reflects broadly measurable changes in population and in per capita utilization. For each of 15 post-war years it is possible to estimate roughly, for most of the 40 countries included, total and per capita amounts of wheat used annually for food, feed, and seed. The prospects for expansion of world food consumption of wheat are more limited than they have been considered heretofore.

**Variability of cropping systems and yields within the eastern meat producing area of Iowa, W. W. WILCOX and N. V. STRAND** (*Ames: Iowa State Planning Bd., 1936, pp. [2]+30, figs. 9*).—Eight townships each were selected on a basis of soil surveys as representative of the most, intermediate, and least productive soils. Tables show for each group the percentages of soils in each soil productivity class; size of farms; tenure in each size group; percentage of land in corn, hay, and small grains; and farms having specific yields of corn and oats on owned and rented farms in each size group.

Soil abuse in the area is due more to failure to grow sufficient soil-conserving crops than to overcropping to corn. Nearly 50 percent of the farmers on the more productive soils are failing to meet recommendations as minimum acreages of soil-conserving crops. Tenants till a larger proportion of their farms than owners. Tenants' systems of farming tended to be more exploitive on the least productive lands, and they offend to a greater degree in not growing sufficient soil-conserving crops. Average yields of corn and oats on owner farms were slightly higher than on tenant farms. There was no significant difference as between soil groups. The percentage of farms of less than 140 acres was highest on the least productive soils, and a higher proportion of small farms was operated by owners.

**A farm management study of small farms in two areas of Puerto Rico.—I, Carolina-Trujillo Alto; II, Isabela, J. E. McCORD, S. L. DESCARTES, and R. HUYKE** (*Puerto Rico Col. Sta. Bul. 43 (1936), pp. 64, figs. 5*).—This bulletin presents the results of a study of records obtained by personal visits to 138 farms in the Carolina-Trujillo Alto area and 99 farms in the Isabela area. Analysis is made of the farm organization and factors affecting labor income in each area.

The factors having the greatest apparent effect on labor income were gross receipts, total and per cuerda (0.97 acre), cash labor costs per cuerda in crops, percentage of total value of products sold, and crop index.

"On the individual farms, as the number of the more important of these factors increased above average the higher were the labor incomes. Those farmers who had the best organized business enterprises had returns for their own labor from 3 to 10 times greater than the average. Basically, the standard of living on small farms depends upon the amount of good land, cash crops of high value per acre, yields higher than the average of the community, and full utilization of land and labor to provide cash income and family living from the farm."

**An economic survey of the commercial broiler industry, W. D. TERMOHLEN, J. W. KINGHOENE, E. L. WARREN, and J. H. RADABAUGH** (*U. S. Dept. Agr., Agr. Adjust. Admin., 1936, pp. V+54, figs. 9*).—Included is factual information regarding the physical set-up of the industry, production, marketing, and costs of production. An intensive study was made of the industry in the Delaware-Maryland-Virginia Peninsula (approximately 66 percent of the commercial

production of the United States is in this area), through questionnaires, county meetings, and personal contacts. Data of the Maryland Experiment Station on costs of production previously noted (E. S. R., 75, p. 412) were used. The industry in the United States and in the area studied is described. The data are analyzed and discussed under the headings of broiler chicks, credit, production costs, local marketing, terminal marketing, prices, and consumption.

[Truck crop growing, grading, and packing in Hawaii], H. H. WARNER, R. H. GAST, and H. B. CADY (*Hawaii Sta. Rpt. 1936, pp. 66-68*).—The comparative prices of graded and standard packed and ungraded tomatoes are given, and a table showing the areas in truck crops and fruits and nuts and number of growers as of June 1936 is included.

Soybean costs and production practices, R. C. ROSS (*Illinois Sta. Bul. 428 (1936), pp. 341-388, figs. 4*).—This bulletin is based on detailed cost records covering the period 1928-34 on farms in Champaign and Piatt Counties and enterprise cost records in 1928 and 1929 from 226 farms in 10 central counties and 2 other counties. Analysis is made of the relations to yield of amounts of labor and power, cultivation, width and time of planting, and variety; inoculation and seed costs; costs of production and of harvesting by different methods; time of and losses in harvesting; value of straw; and methods of disposing of beans to costs of production. The income and profit from soybeans and their place on central Illinois farms are discussed.

Total acre costs of production in 1934 were \$17.95 for beans harvested with binder and thresher, \$14.89 with combine, and \$16.36 for hay. Preharvest costs declined markedly from 1928 to 1934 due largely to reductions in the price of seed and rates for labor and power. Harvesting with combines required less than one-third as much man labor and less than one-sixth as much horse work as with binder and thresher. Grain yields increased about 0.94 bu. per acre with each additional input of man labor up to from 5 to 5.5 hr. per acre. Losses of beans were much greater with binders and threshers than with combines. Man labor per acre for ground preparation, seeding, and cultivation varied from 1.5 to 10 hr. Horse labor increased with man labor, but tractor use was relatively constant. Hay yields were affected but little by amount of labor input before harvest. Row planting showed no particular advantage in yield over drilling solid. The soybean acreage on the farms studied increased from 16.5 percent of the farm area in 1928 and 1929 to 36 percent in 1935, and in the latter year exceeded the acreage in corn. The crop was generally profitable in 1928-30 and in 1934. From 1930 to 1934 soybeans were more profitable than corn, but the price relationships were abnormal.

Financial management of farmers' creameries as affected by volume and prices, A. MIGHELL and P. E. QUINTUS (*Iowa Sta. Bul. 351 (1936), pp. 40, figs. 8*).—This bulletin is based on a series of annual reports for 19 cooperative creameries in Iowa using a uniform system of supervised creamery accounting, 1929-34, and the comparable records of 66 cooperative creameries in 1933, "The study includes a brief description of the creamery business as reflected in the financial statements, with special reference to the effect of volume on creamery operating costs and margins. It should be of interest to managers, boards of directors, and farmer patrons." In the analysis the creameries were divided into four groups on the basis of volume of butterfat handled.

The operating expenses in 1933 for the 66 creameries averaged 3.8 ct. per pound of butterfat in those handling less than 250,000 lb. of butterfat, 3.24 ct. for those handling from 250,000 to 450,000 lb., 2.67 ct. for those handling from 450,000 to 650,000 lb., and 2.37 ct. for those handling over 650,000 lb. The cost ranges were 4.95-2.72 ct., 4.5-2.3 ct., 3.46-2.07 ct., and 3.44-1.72 ct., respectively, and the margins retained by the creameries averaged 3.71 ct., 3.31 ct., 2.89

ct., and 2.57 ct., respectively. The average financial ratios for the 66 creameries as of December 31, 1933, were: Current assets to current liabilities 1.34:1, net worth to total liabilities 2.22:1, net worth to fixed assets 1.15:1, net worth to capital stock 1.94:1, and pounds of butterfat per \$1 fixed assets 37.1. The creameries handling over 650,000 lb. of butterfat had higher average ratios in all cases and the group handling from 450,000 to 650,000 lb. in all but the net worth to capital stock ratio.

The net incomes of 17 creameries studied in 1933 were from 0.1 to 0.92 ct. per pound of butterfat less than the cost in the 5 mo. from January to March and November and December. In the other 7 mo. it was from 0.09 to 0.83 ct. per pound higher.

The total volume of butterfat handled by 19 creameries increased from approximately 365,933 lb. in 1929 to 561,498 lb. in 1934, the annual increases ranging from approximately 43,600 to 50,500 lb. The average operating expenses per pound of butterfat decreased from 3.72 to 2.66 ct. in 1933 and then increased to 2.81 ct. in 1934. The margins retained by the creameries decreased from 3.84 to 2.84 ct. in 1933 and then increased to 2.93 ct. in 1934.

**Livestock marketing methods in Denmark, Great Britain, and Canada,** G. SHEPHERD (*Iowa Sta. Bul.* 353 (1937), pp. 113-160, figs. 9).—The recent developments in livestock marketing practices and how farmers are meeting their marketing problems in the three countries are discussed.

**The marketing of Australian and New Zealand primary products,** W. M. SMITH (*London: Isaac Pitman & Sons, 1936, pp. XVII+352, figs. 3*).—The operation of the existing mechanism by which commodity exchanges are effected between Australia and New Zealand and the United Kingdom and the equity of the adjustments that have been made under existing trade agreements are discussed in chapters on the impulse to large scale marketing, legal aspects of marketing organization, marketing control organizations, the structure of the markets, the problem of maximizing returns to producers, and the marketing prospect.

**Crops and Markets, [December 1936]** (*U. S. Dept. Agr., Crops and Markets, 13* (1936), No. 12, pp. 405-472, figs. 3).—Included in addition to the usual livestock estimates, market reports, and data as to the price situation and price movements of important agricultural products are the final crop reports for the year 1936 with comparisons with 1935 and tables showing the estimated gross costs, credits, and net costs per acre and net cost per bushel of producing corn, wheat, and oats in 1935 by groups of States and the estimated gross costs, credits, and net cost per acre and per pound of lint in producing cotton in 1935.

**Variations in retail prices of certain branded foods,** M. G. RED and E. SCHICKELE (*Jour. Home Econ., 28* (1936), No. 10, pp. 691-695, figs. 2).—Data were obtained on the prices of 28 branded commodities in 8 stores in Ames, Iowa (a college town of about 10,000 population) on Tuesdays and Saturdays from February 26 to June 18, 1935. The average number of price changes per commodity was 2.4, varying from 1.3 to 4.2 for the different stores and from 1 for cocoa to 5.6 for canned peas. In the 3 stores with the greatest number of price changes, Tuesday prices averaged 0.6 percent higher than Saturday prices for the 28 commodities and 1.2 percent higher for the 16 commodities having the greatest number of changes.

The limited survey showed "(1) in some grocery stores prices are much more stable than in others; (2) price changes are more frequent for some staple commodities than for others; (3) Saturday markdowns are not entirely counterbalanced by markups, but they are offered on so few items at a time that the effect on the general price level is rather negligible; (4) the

great frequency of price change, especially for certain products, makes it very difficult to compare the price levels in competing stores; [and] (5) important savings are possible to one who is willing continually to shop from store to store and to keep a record of regular prices by means of which unusually low prices can be recognized."

**Organization and management of consumers' cooperative associations and clubs (with model bylaws)** (*U. S. Dept. Labor, Bur. Labor Statis. Bul. 598 (1934), pp. VI+71*).—Information is presented on the methods of organizing and operating consumers' cooperative associations and clubs. Model bylaws for such associations and clubs are included.

**Membership relations of cooperative associations**, J. W. JONES (*Farm Credit Admin. [U. S.], Coop. Div., Bul. 9 (1936), pp. IV+111*).—The influence of the association structure, attitudes of managers and directors, member's position in the association, means of making contact with the membership, expense of membership service, and house organs and other means of publishing news are described and discussed.

**Consumers', credit, and productive cooperation in 1933**, F. E. PARKER (*U. S. Dept. Labor, Bur. Labor Statis. Bul. 612 (1935), pp. VI+80*).—The results of a statistical study of the 1933 experience of all types of cooperative associations in the United States (except farmers' marketing associations) are presented under the headings of consumers' organizations, central consumers' organizations, credit and banking societies, and workers' productive associations.

**Ohio agricultural statistics, 1935**, G. S. RAY, L. H. WILAND, and P. P. WALLRABENSTEIN (*Ohio Sta. Bul. 577 (1936), pp. 88, fig. 1*).—This bulletin, prepared in cooperation with the U. S. D. A. Bureau of Agricultural Economics, continues the series previously noted (*E. S. R.*, 74, p. 409). In addition to the preliminary county estimates for crops for 1935 and numbers of livestock on farms January 1, 1936, it includes revised county estimates for 1930-34 for corn, wheat, and oats, for 1929-34 for potatoes and tame hay, and for January 1, 1930-35, for numbers of livestock on farms.

## RURAL SOCIOLOGY

**First annual report, Resettlement Administration** (*Resettlement Admin. [U. S.], Ann. Rpt., 1 (1936), pp. VIII+173, pl. 1, figs. 35*).—This report covers progress in land utilization, rural rehabilitation, rural resettlement, and suburban resettlement.

**Planning for city, State, region, and Nation: Proceedings of the Joint Conference on Planning, May 4, 5, and 6, 1936, Richmond, Virginia** (*Chicago: Amer. Soc. Planning Off., 1936, pp. VIII+170*).—These proceedings of a meeting of the Joint Conference on Planning of the American City Planning Institute, American Planning and Civic Association, and the American Society of Planning Officials included papers as follows: County Planning in Iowa, by P. H. Elwood (pp. 54-58), Distinctive Features of Planning Procedure in Clackamas County, Oregon, by L. C. Stoll and V. B. Stanbery (pp. 59-65), and County Agricultural Adjustment Planning, by B. W. Allin (pp. 66-71); on intercounty organization—The Georgia Eastern Coast District, by H. T. McIntosh (pp. 72-74), and Tennessee Counties, by G. Gimre (pp. 75-77); and on the progress of State planning in Massachusetts by E. M. Herlihy (pp. 81-87), South Dakota by W. R. Ronald (pp. 87-90), Florida by C. B. Treadway (pp. 91-94), New Jersey by C. P. Messick (pp. 94, 95), and Virginia—State Planning and Education, by S. B. Hall (pp. 96, 97), State Planning and Conserva-

tion and Development, by W. C. Hall (pp. 97-101), and State Planning and Legislative Planning, by W. R. Shands (pp. 101, 102). Other papers are included on city and national planning.

**Report of the Illinois State Planning Commission, December 1934** ([*Springfield*]: *Ill. State Planning Comn.*, 1935, rev., pp. [8]+91, [figs. 47]).—This report presents facts as to the population, natural resources, land utilization, transportation, private industry, and public works of the State; draws conclusions thereon; and makes preliminary recommendations for the State.

**Preliminary report, State Planning Board of Indiana** ([*Indianapolis*]: *Ind. State Planning Bd.*, 1934, vol. 1, 2. ed., pp. [6]+163, [pls. 79]).—This volume includes data on the living conditions, gainful occupation, land use, and transportation of Indiana, and discusses the public works program recommended and legislation necessary to carry it into effect.

**Proceedings of Southeastern Planning Conference, Savannah, Georgia, December 4-5, 1935** (*Albany, Ga.*: *Natl. Resources Com.*, Fourth Dist., [1935], pp. [4]+96, [pl. 1]).—Included are the following papers or summaries of papers presented at a 1935 conference of the Fourth District National Resources Committee (Alabama, Georgia, Florida, and South Carolina): Organization of City and County Planning Boards, by R. H. Randall (pp. 9-14); State Planning, by M. L. Wallerstein (pp. 15-23); State Planning in Florida, by C. B. Treadway (pp. 24-28); A Forestry Program, by J. C. Kircher (pp. 29-37); Citizen Support of Planning, by F. A. Delano (pp. 38, 39); Plan in Our Future, by D. Sholtz (pp. 40, 41); The Gulf-Atlantic Ship Canal and the Southeastern States, by S. L. Lowry, Jr. (pp. 42-52); Cooperation of Federal Agencies Through National Resources Committee, by R. H. Randall (pp. 53, 54); Federal, State, and Local Cooperation in Planning the Works Program in Georgia Under CWA, FERA, and WPA, by G. B. Shepperson (pp. 55-59), with discussion, by P. A. Fellows (pp. 60-73); The Rural Resettlement Program, by P. Weltner (pp. 74, 75), with discussion, by W. A. Hartman (pp. 76-81); Maps and Mapping the Sine Qua Non for Planning, by B. R. Van Leer (pp. 82-91); and Regional Planning, by E. S. Draper (pp. 92-95).

**Maine State Planning Board Report, 1934-1935** (*Maine State Planning Bd. Ann. Rpt.*, 1 (1935), pp. [2]+XIV+396, pls. 2, figs. 243).—This report covers the year ended March 15, 1935, reviews the planning procedure and research of the board, and describes the board's program for public works. Data are presented as to transportation; land use and agriculture; conservation; recreation; public utilities; sanitation, public health, and welfare; social conditions; industry and commerce; water resources; climatology; public administration, and surveys and maps.

**Report of the Virginia State Planning Board, IX. Pt. 17, Mobility and changes of populations in Virginia, 1930 to 1935** ([*Richmond*]: *Va. State Planning Bd.*, 1936, vol. 9, pt. 17, pp. III+84, pls. 18).—Data analyzed in this report include those dealing with natural gains, the school census, the agricultural census, and probable populations and composition changes as in 1935.

**The hill country of northern New England: Its social and economic history, 1790-1930**, H. F. WILSON (*New York: Columbia Univ. Press*, 1936, pp. XV+455, [pls. 4, figs. 13]).—The readjustments in agriculture in northern New England from 1790 to 1930 and the forces responsible for the readjustments are described.

**[Iowa State Planning Board, second report, 1935]** ([*Ames*]: *Iowa State Planning Bd.*, 1935, pp. XXIV+226, pls. 8, figs. 129).—This second report (E. S. R., 72, p. 548) is divided into parts as follows: Land, with sections on need for adjustment, recommended physical adjustments, proposed plans for advancing such adjustments, wildlife areas and land use planning, and part-time

farming; water, with sections on investigations, field work, and the lower Des Moines River Valley; people, with sections on population and social trends, public education, Iowa's housing problem, proposed program for recreation, zoning and planning, and historic and scenic sites; and commerce, with sections on planning Iowa's transportation system, public service in the State, surveys of business and industry, and a program for public works construction in the State.

**Rural organizations and land utilization on Muscatine Island: A study of social adjustments**, R. E. WAKELEY and J. E. LOSEY (*Iowa Sta. Bul.* 352 (1936), pp. 41-111, figs. 14).—Muscatine Island, located south of the city of Muscatine, has an area of 22,000 acres, 17,000 of which are suitable for farming.

While floods, occasional drought, and a sandy soil discouraged corn growing, by 1870 the commercial production of melons and cantaloups was firmly established. Sweetpotatoes soon became one of the most important crops. Production of other vegetable crops, including cabbage, tomatoes, cucumbers, and asparagus, increased during the decade following the Civil War. Canning factories, established in Muscatine, encouraged the growing of these crops, and large acreages were grown on the heavier soil near Muscatine. The isolation of the island from the surrounding farming territory was increased by this change in type of farming.

By 1900 increased production of melons in other parts of the United States and the use of refrigerator cars increased the competition. Marketing problems became acute. Melon wilt became a major factor in island agriculture in 1908, making it impossible to produce a profitable crop of melons oftener than once in 7 yr. Idle land and resulting lack of income remained major problems at the time of this study.

The creation of a drainage district in 1914 made a large part of the swampy land along the slough available for agricultural purposes. This increased the number and importance of the heavy-land farmers who specialized in the production of grain and livestock.

Population data are presented for the 160 families interviewed. Of the total of 727 persons, 595 in 134 families lived on farms.

Approximately one-third of the families on the island are of German descent and the rest of English extraction. The foreign-born were mostly past 45 yr. of age and constituted a very stable element in the population.

Natural families averaged 4.7 persons per family. Farm families averaged 4.8 persons and nonfarm families averaged 4.2 persons per natural family.

Only 23 percent of the farm operators and only 9.2 percent of the wives of operators were born on the island. No farm family had lived on the same farm for more than two generations. The average period of residence on their present farm was 13.1 yr., and on the island 26.1 yr.

Island homes were seriously lacking in modern conveniences and equipment. Less than 1 in 6 had electric lights, 1 house in 30 had piped hot and cold water, and 1 in 20 had a furnace. Island homes excelled in the number of homes with water pumped in the house by hand pumps, usually located in the kitchen.

Expenditures by all island families for health and medical care were small. Twenty families of the 175 living in Fruitland Township received relief, ranging in amount from \$2 to \$20 per month during the winter of 1933. Only six families in the sand-land area received relief, and only three of these were farm families.

Elementary schools gave all the education obtained by nearly three-fourths of the island population 15 or more years of age. All had attended school but 5 percent had not passed fourth grade. Ten percent had received some educa-

tion above grade school, less than 1 in 25 had attended college, and none had been graduated from college.

"Generally expressed, the interests of island farmers rank as follows: First, church activities; second, social activities; third, home development; fourth, scientific farming; fifth, school activities; sixth, farmer organizations; seventh, politics; eighth, young people's activities. Nearly 50 percent more families expressed church interests than any other. Scientific farming, home development, and school activities were about equally strong."

**The Japanese rural community**, F. R. YODER (*Rural Sociol.*, 1 (1936), No. 4, pp. 420-429).—The author studied Japanese rural social life for 10 mo. and made brief general surveys of 14 Japanese rural communities.

The convenient rural community unit for study in Japan is the mura, a rather self-sufficient rural unit containing the mura government hall and offices, a 10- to 20-room elementary school, a dozen or more Shinto shrines and Buddhist temples, a post office, small trading shops, buildings and headquarters of farmers' cooperative societies, and various types of fellowship and amusement center facilities and buildings. The very small size of farms makes the mura a compact social unit. The average size of farms for all Japan is only 2.7 acres, with only 1.3 percent over 12 acres. The Japanese peasant families are voluntarily bound together in little groups of five households each for purposes of mutual help and protection.

The land and tenure system of Japanese agriculture affects the structure and the social relationships of the rural community. As late as 1873 most of the agricultural land was held by a relatively small number of landlords, and the great mass of rural dwellers worked as serfs on the land. The government undertook in 1873 to redistribute the land among the workers on the soil, but while land has been made a marketable economic good, it changes hands or families only with the greatest difficulty and thus inflexibility holds the rural community to a rather rigid cultural pattern.

The local agricultural society is a cellular unit of the Imperial Agricultural Society, national in its scope and organization. Practically every rural community also has its cooperative buying, selling, utilizing, and credit societies, of which more than half of the Japanese farmers are members. The local societies are federated into provincial and national associations.

While the Japanese rural people are fairly religious, worship is rather by families and individuals than by groups. Only on certain festival, holiday, and patriotic occasions is there a manifestation of communal worship at the shrines and temples, but these are likely to be large community events for the peasants.

The rural elementary schools are of large size, usually having from 10 to 20 teachers and from 500 to 1,000 pupils. The superintendents of the schools are highly respected by the community and are quite often leaders in its activities and organizations.

The local government of the mura is closely tied in with the agriculture of the community. The mayor is often the president of the local agricultural society or of one or more of the cooperative societies.

The chief changes that have taken place in Japanese agriculture have been in the increase of scientific methods of cultivation, selection and improvement of varieties of plants, yields per acre, and development of agricultural associations and cooperative societies. The social organization of the rural community has changed little in many years. Japan as a nation, therefore, presents a strange contrast of almost medieval rural communities alongside modern machine-made cities.

**With rural relief in Colorado, February–November 1935, O. F. LARSON** (*Colorado Sta. Res. Bul. 1* (1936), pp. [3]+28, figs. 5).—This is the first of a series of bulletins planned to present selected phases of the rural relief situation in Colorado as found in representative counties from February to the end of November 1935. It gives the reasons for opening and closing rural relief cases, shows what disposition was made of such cases when the Federal Emergency Relief Administration stopped giving assistance, and describes the type of cases selected by the various agencies to which cases went from the rural relief rolls. The basis for the information presented is data collected by the survey of current changes in the rural relief population, a study made by the social research division of the Works Progress Administration.

**Social security and rural relief in Colorado, O. F. LARSON and J. E. WILSON** (*Colorado Sta. Res. Bul. 2* (1936), pp. [5]+12+[1], figs. 4).—This report describes the extent and characteristics of cases which received general assistance from the Emergency Relief Administration between June and the end of November 1935, and which were potentially eligible for such specified aid under the social security program as old age assistance and aid to dependent children. Data are presented as to the extent and characteristics of cases which were unemployable or potentially unemployable. Some of the types of "problem cases" discovered in these rural areas are discussed.

**Rural youth and relief in Colorado, O. F. LARSON and J. E. WILSON** (*Colorado Sta. Res. Bul. 3* (1936), pp. [4]+16, pl. 1, fig. 1).—Data are presented which show the number and distribution of rural youth aged 16–25 who were in households receiving general assistance from the Emergency Relief Administration during the period between June 1 and November 30, 1935. A description is given of some of the characteristics of these youth which are considered important from the standpoint of aiding youth adjustments. These characteristics include family status, educational attainments, employment status, and occupational experience. A limited comparison is made of relief and nonrelief youth.

**Contemporary background of California farm labor, P. S. TAYLOR and T. VASEY** (*Rural Sociol.*, 1 (1936), No. 4, pp. 401–419, figs. 7).—As pointed out in a previous article (E. S. R., 76, p. 266), the value of intensive crops represented less than 4 percent of the total value of California agricultural production in 1879, but by 1929 it was practically four-fifths of the total. Demand for farm labor in California is heavy because of this intensive crop production and also concentrated to a marked degree because of the scale of farm operation. More than one-third of all large-scale farms in the entire country were located in California in 1930. The large farm is very prominent in the rural economy, and the large grower exercises great influence in councils of agricultural employers.

The tenuousness of the connection of California farm laborers with the farm is further emphasized by the fact that only 43.5 percent resided on the farm in 1930, as compared with 74.4 percent of paid farm laborers in Mississippi.

California agriculture has thus built up a rural proletariat, partly of alien race, propertyless, without ties to the soil which it tills, and subject to regular unemployment caused by the highly seasonal demand for labor which at its slack in January is only 23.4 percent of the peak demand of September. High mobility has therefore become a necessary characteristic of those who "follow the crops."

Decline of cotton production in Imperial and Riverside Counties was followed almost immediately by tremendous expansion in the San Joaquin Valley of central California with corresponding changes in the need for seasonal labor.

Scores of thousands of men, women, and children in California live part or all of the year literally "on wheels." In April 1927, the California Department of Education enumerated 37,000 migratory children. The migrants follow the harvests and when these are over the opening of the next season is awaited in the small town and urban slum areas of the State in partial or complete idleness.

The family farm, which still expresses the national ideal, is subordinate in California to the influence of agriculture on an industrialized pattern.

**Preface to peasantry**, A. F. RAFFER (*Chapel Hill: Univ. N. C. Press, 1936, pp. XIII+423, [pls. 44, figs. 22].*).—This is a study of rural Negroes and whites living on the fringe of the economic system in Griffin and Macon Counties, Ga., as typical of the cotton-growing sections of the old South.

**The relation of density and aggregation of population to the family**, D. SANDERSON ([*New York: Cornell Sta. Rpt. 1936, p. 138*]).—The study shows the proportion of persons married, single, widowed, or divorced, and the age at marriage as associated with the size of the community for native whites of native parentage.

**The trend of the marriage rate in rural North Carolina**, C. H. HAMILTON (*Rural Sociol., 1 (1936), No. 4, pp. 452-471, figs. 6*).—This paper is based on a study of 1,703 families located in representative open-country areas of five North Carolina counties. About one-half of the households were in the two Piedmont areas and the other half in the three Coastal Plain areas. The 15- to 29-yr. age group has been used as a basis for calculating marriage rates.

During the depression years 1932-34 the marriage rate of the relief population was significantly and substantially below that of the nonrelief population. Over a long period of time, however, no significant difference was found.

In two cotton counties, Johnston and Robeson, of the North Carolina Coastal Plain, there appears to be a highly significant correlation between marriage rates and average local cotton prices of the previous year as reported by the North Carolina Department of Agriculture. Young farm people, two-thirds of whom remain on farms, respond to the pressure of economic circumstances in much the same way as their city cousins. In times of poor prices farm youths delay marriage and the beginning of their careers. When recovery sets in, the marriage rate for rural youths responds very quickly because of delayed marriages. Consequently, the marriage rate of the nonrelief population rose substantially in 1933, whereas the marriage rate of households (to be on relief in 1934) continued to decline.

Females marry approximately 3 yr. earlier in life than males. Older males (from 20 to 29) marry at more nearly the same rate as females than is the case with younger males and females. There is no significant or uniform difference in the paces at which the various marriage rates change from year to year.

Beginning as early as 1927, the marriage rates for Negroes, male and female, began to decline, whereas the marriage rates for white persons changed very little. The marriage rate for white females, after dropping slightly in 1929, 1930, and 1931, increased rapidly in 1932 and 1933. The marriage rate for white males was most constant of all, but it followed the white female rate upward in 1932 and 1933.

The marriage rate of the population in or from farm-owner families (as of 1934) was somewhat lower than that of the nonowner group. Marriage rates of owner and nonowner groups are closely and positively correlated, and the rates for both groups have risen since 1931.

**The rural church today and tomorrow: A report of the National Conference on the Rural Church** (*New York: Home Missions Council and Council*

of Women for Home Missions, 1936, pp. 90).—This is a report of the National Conference on the Rural Church held by the Home Missions Council and the Council of Women for Home Missions, in Washington, D. C., January 13-17, 1936.

### AGRICULTURAL AND HOME ECONOMICS EDUCATION

**Authority of State executive agencies over higher education, J. H. McNEELY** (*U. S. Dept. Int., Off. Ed. Bul. 15* (1936), pp. III+57, figs. 48).—A diagram for each State indicates "schematically the governing boards of the institutions of different types and the particular State executive-officials and agencies vested with authority over them. Each specific power conferred on an official or agency dealing with the internal administrative affairs of the institutions has been paraphrased in abbreviated fashion in the diagrams."

**Young men in farming, E. R. HOSKINS** (*U. S. Dept. Int., Off. Ed., Vocat. Ed. Bul. 188* (1936), pp. V+117).—This is a study of young men to determine the qualifications, opportunities, and needs for training in farming, together with derived guidance, placement, and training objectives. Data were obtained by personal visits for 100 young men from 15 to 25 yr. of age in the northern part of Tompkins County, N. Y., of which 38 were fully established in farming and expressed no desire to change occupation, 44 were partly established in and intended to continue in farming, and 18 were not yet established and doubtful as to their desire to continue in farming. Analyses are made showing the attitudes toward farming, the age, physical characteristics, and nationality, education, receipts and expenses before and after leaving school, net worth of the young men, agricultural and human resources and modes of life of the area, the home farms as business enterprises, and family relationships and adjustments. The experience and status of the young men, particularly those established and partly established in farming, are discussed and illustrated by cases. The curriculum objectives in agriculture suitable for such a group of young men are outlined and discussed under the headings of guidance, placement, and training objectives.

### FOODS—HUMAN NUTRITION

**Foods and nutrition [at the Hawaii Station]** (*Hawaii Sta. Rpt. 1936*, pp. 58-66, figs. 6).—This progress report (E. S. R., 75, p. 415) includes brief summaries of studies by C. D. Miller and R. C. Robbins on the nutritive value, including vitamin content, of the papaya; by M. Potgieter, Miller, and Takase on the vitamin content and total and available calcium of the taro; by Miller and Robbins on the absorption of vitamin B from rice bran by Chinese cabbage, daikon, and eggplant when pickled in a paste of salt and rice bran, with tabulated data on the proximate and mineral composition of these vegetables when fresh and bran-salt pickled; by Miller and Robbins on the nutritive value, including minerals and vitamins, of the opihī, and the proximate and mineral composition of the marine alga limu kohu; and by C. J. Hamre and Miller on the blood and blood-forming organs of adult rats in recovery from nutritional anemia.

**Report of the Food Investigation Board for the year 1935, F. E. SMITH ET AL.** ([*Gt. Brit.*] *Dept. Sci. and Indus. Res., Food Invest. Bd. Rpt., 1935*, pp. X+232, figs. 80).—The report summarizes the progress of the investigations carried out during the year, including sections on meat; poultry and eggs; pork, bacon, and hams; fish; fruit and vegetables; canning; and engineering.

**Correlation of experimental and commercial baking tests, J. FRELICH, S. McHUGH, and C. N. FREY** (*Cereal Chem.*, 12 (1935), No. 6, pp. 668-691, figs.

11).—To find a correlation between laboratory and large-scale baking results, a study was undertaken of the different steps in the straight dough procedure, using a typical commercial formula and following the usual baking procedure. Differences were noted between machine molded and hand molded breads and between breads baked in bakery ovens and in the laboratory. Otherwise the differences were very slight, demonstrating that laboratory conditions can be adjusted to produce results equal to those obtained in the bakery if a machine mold is used and the loaves are baked in a small laboratory oven similar in construction to bakery ovens.

**The occurrence of acetylmethylcarbinol in bread and its relation to bread flavor**, F. V. HOOFT and F. J. G. DE LEEUW (*Cereal Chem.*, 12 (1935), No. 3, pp. 213–229, figs. 7).—Acetylmethylcarbinol has been identified as a constituent responsible for the characteristic flavor of good bread. A method for its determination in doughs and finished bread is given, and the term “acetylmethylcarbinol figure” or “A. F.” is proposed to indicate the number of milligrams of acetylmethylcarbinol found in 150 g of bread dough or bread crumb. Factors found to have a favorable influence on the A. F. are high sugar:yeast ratio, diastase preparations, low fermentation temperature, short fermentation time, sponge-dough method, hydrogen acceptors or oxidizing agents and oxygen, and proper yeast selection.

**Peanut meal: Food value and uses**, L. ASCHAM (*Georgia Sta. Bul.* 195 (1936), pp. 18, figs. 10).—About 40 standard recipes accompanied by modifications to incorporate peanut meal are presented in this bulletin.

**Frozen desserts**, P. H. TRACY (*Illinois Sta. Circ.* 462 (1936), pp. 28, figs. 17).—In this revision of Circular 377 (E. S. R., 66, p. 89), the section on types of freezers includes a description of a new motor-driven freezer developed for use in the freezing unit of a household refrigerator, and the section on recipes for the automatic refrigerator has been extended to include quantities of various materials to use for flavoring ice cream, recipes for sirups, and suggestions for a variety of ice cream sundaes.

**Studies of numbers and types of microorganisms in frozen vegetables and fruits**, A. G. LOCHHEAD and A. H. JONES (*Food Res.*, 1 (1936), No. 1, pp. 29–39, figs. 2).—Frozen-pack asparagus, peas, beans, corn, strawberries, and raspberries were studied. The vegetables were packed dry, in water, or in 3 percent brine solution. The fruits were packed in sugar sirup. All products were packed in paraffin-lined cartons and stored at  $-17.8^{\circ}\text{C}$ . Duplicate cartons were defrosted at  $37^{\circ}$ , and the number of coli-aerogenes organisms, anaerobic spores, yeasts, and molds were estimated.

A wide variation was noted in microbial count of freshly packed materials, but this tended to become obliterated during storage. The method of packing did not significantly affect the organism count except with the corn, which contained a considerably larger proportion of bacteria surviving with the water pack. Bacteria predominated in the vegetable packs, while yeasts and molds were more numerous in the acid fruit packs. The coli-aerogenes type of organism decreased during the first 6 weeks of freezing to an insignificant content, while the anaerobic spores persisted in small amounts. The experiments indicate that appreciable amounts of micro-organisms may remain alive even after 9 mo. of storage at  $-17.8^{\circ}$ .

Additional tests showed enormous increases in bacterial count in vegetables defrosted at room temperature for  $1\frac{1}{2}$  or  $3\frac{1}{2}$  days, with only moderate increases when defrosted at refrigerator temperatures at from  $5^{\circ}$  to  $10^{\circ}$ . Relatively smaller increases were noted in the fruits tested under similar conditions. The coli-aerogenes organism increased only in the vegetable samples held at room temperature. Anaerobic spores and coli-aerogenes organisms

showed no development in the fruits. Further tests demonstrated that micrococci and species of *Flavobacterium* survived freezing relatively better than other types of bacteria. The results emphasize that fruits and vegetables, when frozen promptly and kept frozen uninterruptedly, are safe from microbial spoilage, but should be regarded as distinctly perishable products and consumed promptly on defrosting.

[Nutrition studies by the Cornell Station] ([New York] Cornell Sta. Rpt. 1936, pp. 87, 88).—Brief notes are given on studies conducted on rats by C. M. McCay, L. A. Maynard, and M. Crowell on the effect of the protein level on health after middle life; basal diets for vitamin B<sub>1</sub> assays, by McCay; and the effect of low levels of fluorine intake on the bones and teeth, by Maynard and G. Ellis.

Food values—what they are and how to calculate them, M. McKILLOP, rev. by E. C. MOTTRAM (London: George Routledge & Sons, 1936, [4. ed., rev.], pp. XI+155).—This volume, the first edition of which has been noted (E. S. R., 36, p. 663), revises and brings up to date the practical application of existing knowledge on nutrition. Following the introductory review of nutrition, the food requirements and vitamins are discussed. "The brown bread controversy" is the subject of one chapter. The remainder of the book is devoted to food value tables and recipes, with calculations on nutritive values.

The significance and accuracy of biological values of proteins computed from nitrogen metabolism data, H. H. MITCHELL, W. BURROUGHS, and J. R. BEADLES (*Jour. Nutr.*, 11 (1936), No. 3, pp. 257-274).—This contribution from the Illinois Experiment Station describes a series of paired rat-feeding trials in which the proteins of beef round were compared with those of raw peanuts, roasted peanuts, and pecans. Biological values of the proteins were determined by the nitrogen balance method and checked against the comparative nutritive values of the proteins as measured by the growth rates obtained under the paired feeding method, supplemented by carcass analyses.

The biological values of these proteins averaged 76, 58, 56, and 60, respectively. The biological value for a given protein as determined by the nitrogen balance method with a number of individual test animals showed an average standard deviation of 3.7, this tending to be larger the smaller the biological value. The relative nutritive equivalence of two protein mixtures was practically the same whether evaluated by the nitrogen balance or the paired feeding method, indicating that biological values as determined by this laboratory method possess an absolute as well as a relative significance.

Diet in relation to physical efficiency, G. E. FRIEND (*Brit. Med. Jour.*, No. 3944 (1936), pp. 276-278).—The author discusses school and institutional feeding and reviews the conclusions drawn from a 20-yr. survey of the diets of boys living at a hospital school. The various requirements of a normal diet and the division of calories for protein, fat, and carbohydrate advanced by the British Medical Association committee on nutrition are outlined. It is thought that improvement in the health and efficiency of school children would result if the requirements for adequacy could be met and the knowledge acquired through research applied to the question of diet in relation to physical efficiency.

Physical growth of white children: A review of American research prior to 1900, H. V. MEREDITH (*Natl. Res. Council, Soc. Res. Child Develpmt. Monog. No. 2* (1936), pp. [3]+83).—The author presents in chronological order a critical review of research published between 1858 and 1900 dealing with growth in external bodily dimensions of physically normal American white children, ranging in age from birth to 18 yr. An extensive list of literature references is included.

**Diets of low-income families surveyed in 1933, D. G. WIEHL** (*Pub. Health Rpts. [U. S.], 51 (1936), No. 4, pp. 77-97, figs. 3*).—This is a statistical study of the adequacy of the diet in a large number of low-income families living in New York City, Birmingham, five large industrial cities in the North, South Carolina cotton mill villages, and a mining district of West Virginia. Detailed records of the food supply of each family were kept over a 1-week period, and the results were compared with the Stiebeling and Ward standards of a so-called "adequate" and a "restricted" diet (*E. S. R., 70, p. 416*).

Among the families living in the five Northern industrial cities having a weekly income of less than \$2 per person, the average energy value of the food supply was approximately 20 percent below the adequate standard of 3,000 calories per day per adult male unit, and in one-fourth of these families the average intake was less than 2,200 calories daily. Among the lowest income families, the greatly diminished supply of milk, vegetables, and fruits was very apparent. This deficiency in the protective foods resulted in a diet of very poor nutritional balance, particularly lacking in calcium and vitamins. In Birmingham the average intake at all income levels equaled or exceeded the standard, but the number of families is too few to warrant considering the results typical. In New York City the families with \$3-\$4 and lower incomes showed an average fuel value of approximately 20 percent below the adequate standard, with the lowest income families including in their diets an adequate amount of vegetables and a minimum amount of milk, with less than the recommended quantities of the cheap high caloric foods such as bread, cereals, potatoes, and dried legumes. In the South Carolina villages and the West Virginia mining towns for each income group the calories averaged more than 3,000 per day per adult male unit. The lowest income families studied in these two States purchased less than half of the recommended amount of milk and included very small quantities of fruits in the diet.

In a previous survey a consistent correlation of the sickness rate with the economic status of the families was demonstrated, and the results of this study show that this was in part due to an unbalanced and insufficient dietary.

**Nutrition and national health, I-III, R. MCCARRISON** (*Jour. Roy. Soc. Arts, 84 (1936), Nos. 4371, pp. 1047-1066, figs. 3; 4372, pp. 1067-1083, fig. 1; 4373, pp. 1087-1107, figs. 3*).—The three Cantor lectures of 1936, delivered before the Royal Society of Arts, are here given.

**I. Food, nutrition, and health.**—The author reviews the principles of nutrition and surveys his research studies with human subjects and experimental animals to show that nutrition is a vital factor in physiological well-being. Emphasis is placed on the importance of using whole cereal grains, milk and milk products, eggs, fruits, and fresh vegetables in adequate quantities to maintain the structural integrity and functional efficiency of the body.

**II. Relation of certain food essentials to structure and functions of the body.**—This is a discussion of the different parts played by proteins, mineral elements, and vitamins in nutrition and of the effects of their inadequate supply or inadequate utilization when supplied in sufficient quantities. "If the knowledge acquired during the past quarter of a century is to yield its fullest fruit in the betterment of the national health it must be recognized that an optimum supply of all vitamins, in an otherwise well-balanced diet, is a prerequisite of optimum health, and that a minimum supply, while it may suffice for the prevention of certain specific 'deficiency diseases,' creates the conditions precedent to the occurrence of a wide range of other sicknesses. All of which, in regard to vitamins, is not to minimize the great importance of other food essentials in maintaining nutritional harmony and this, in its turn, the melody of health."

**III. National health and nutrition.**—The author discusses the dietary habits and the incidence of disease in different parts of the British Empire. Experimental evidence and reviews of data gained from surveys are presented to show that food of improper constitution and poverty are responsible for a large proportion of the ill health and poor physique of the people. One of the most urgent problems at present is how to insure that each member of the community will receive a diet that will satisfy the physiological needs. "It is clear that to achieve this much-to-be-desired end many barriers—poverty, unemployment, apathy, ignorance, prejudice, habit—must be surmounted, and many interests—agricultural, industrial, and commercial—readjusted." The author stresses the need for greater consumption of milk and green vegetables, better distribution of and storage facilities for perishable foodstuffs in the poorer urban districts, and education of the public in the principles of dietetics.

[Nutrition in health and disease] (*Lancet [London]*, 1936, II, No. 5, pp. 260–262).—This is an abstract of a discussion before the nutrition section of the British Medical Association at its 1936 meeting. The discussion was opened by R. McCarrison, who reviewed the contacts of the nutrition section with the other sections of the Association. This was followed by discussions by R. A. Peters on the vitamin B complex and its relation to disease, by H. N. H. Green on the fat-soluble vitamins, particularly vitamin A and its relation to infection, by S. S. Zilva on the chemistry of vitamin C as related to its behavior in the body, by D. Hunter on minerals in nutrition, particularly sodium, calcium, phosphorus, and iodine, and by L. Wills on nutritional anemias.

**A purified diet satisfactory for growth, reproduction, and lactation in rats.** W. M. Cox, JR., and M. IMBODEN (*Soc. Expt. Biol. and Med. Proc.*, 34 (1936), No. 4, pp. 443–446).—The authors fed for a period of over 2 yr. and to three generations of rats a diet of casein 20 percent, dextrin 55.1, lard 9, aqueous extract brewer's yeast 4, wheat germ oil 1.6, carotene solution 3:1,000 in corn oil 0.3, calcium acetate 1, a mixture of salts 3.1, and rice cellulose 5.9 percent. Growth, reproduction, and lactation on this diet were as satisfactory as when a standard stock diet was used.

**The relation of diet to the occurrence of gastric lesions in the rat.** E. L. HOWES and P. J. VIVIER (*Amer. Jour. Path.*, 12 (1936), No. 5, pp. 689–700, pls. 2).—Groups of young and adult rats, hooded and albino strains, were placed on a modified Pappenheimer-Larimore (*E. S. R.*, 53, p. 165) lesion-producing diet of flour and salt mixture. After 42 days 90 percent of the young rats developed stomach lesions, accompanied by anorexia, xerophthalmia, and failure to gain weight, while the adult rats remained free from these symptoms for 61 days. When the adult rats were starved every other day, 70 percent developed stomach lesions within 49 days. The young rats showed improved growth when adequate amounts of vitamins A and D were supplied, but 50 percent of them and 60 percent of the adult rats developed lesions. Carotene and butter supplements also failed to protect them. The addition to the diet of 5 percent whole yeast alone or in combination with 5 percent of cod-liver oil or 20 percent of casein protected the young rats from the formation of lesions. An increased quantity of yeast granted protection to the adult rats. When the amount of flour and salt mixture was restricted, 5 percent of whole yeast granted less protection than when a liberal amount of the diet was allowed or when other food factors were supplied. The addition of 10 percent of dried feces to the diet prevented the lesions. The ulcerations occurred in hypertrophied squamous epithelium in the rumen and glandular portions of the stomach. "There is no similarity between these lesions and peptic ulcer in man."

**A study of the dietary factors concerned in nutritional muscular dystrophy,** S. MORGULIS and H. C. SPENCER (*Jour. Nutr.*, 11 (1936), No. 6, pp. 573-591).—Muscular dystrophy was observed in rabbits fed on a diet of rolled oats, wheat bran, casein, lard, cod-liver oil, and salts, the whole diet being mixed and treated with either ethereal or aqueous ferric chloride. When the ferric chloride treatment was omitted a few delayed cases of dystrophy occurred, as shown by clinical observation and histological examination. The results were unchanged when corn oil was substituted for the lard in the ration. Fresh green alfalfa and whole wheat germ both prevented and cured the disease, but dried alfalfa, lettuce, vitamin A as carotene in oil, or vitamin E as cold pressed wheat germ oil were ineffective when given singly. When fresh green alfalfa, lettuce and wheat germ oil, dried alfalfa and wheat germ oil, or whole wheat germ were used to supplement the dystrophic diet, prevention and cure were observed.

Two nutritional factors would thus seem to be involved in the prevention or cure of muscle dystrophy. Both factors are present in fresh green alfalfa and in whole wheat germ, one factor is supplied by cold pressed wheat germ oil, and the other is present in lettuce and in dried alfalfa. Drying, extracting with water or alcohol, or treating with ethereal ferric chloride destroys at least one of the factors.

**The creatine-creatinine excretion and the creatine content of muscle in nutritional muscular dystrophy,** T. G. NI (*Chin. Jour. Physiol.*, 10 (1936), No. 1, pp. 199-206).—In this study nutritional muscular dystrophy was induced in 1-month-old guinea pigs by diet No. II, described by Goettsch and Pappenheimer (E. S. R., 66, p. 796). Preformed creatinine was determined by Folin's method (E. S. R., 31, p. 661), and creatine was estimated as creatinine. Muscle creatine was determined by the method of Rose, Helmer, and Chanutin (E. S. R., 58, p. 500).

The results showed that guinea pigs with symptoms of nutritional dystrophy excreted in 24 hr. in the urine from 22.4 to 53.6 mg of creatine and from 8.1 to 17.2 mg creatinine per kilogram of body weight, while the corresponding excretions for normal guinea pigs were from 6.7 to 14.2 mg creatine and from 20.4 to 22.3 mg creatinine. The muscle creatine for dystrophied animals was found to be from 122 to 375 mg per 100 g of muscle for gastrocnemius, from 175 to 408 mg for adductor magnus, and from 222 to 258 mg for the heart, and for normal animals from 489 to 508 mg, from 465 to 490 mg, and from 227 to 232 mg for the muscle tissues, respectively. The creatine tolerance test showed that the dystrophied animals retained from -15 to +37 percent and the normal animals from 49 to 53 percent.

Muscular dystrophy in young guinea pigs was accompanied, therefore, by a rise in creatine coefficient (milligrams creatine per kilogram of body weight in 24 hr.), a fall in creatinine coefficient, a low creatine content of the muscle except the heart, a decrease in creatine tolerance, and clinical symptoms of paralysis.

**The relation between calcium retention and the store of calcium in the body, with particular reference to the determination of calcium requirements,** B. W. FAIRBANKS and H. H. MITCHELL (*Jour. Nutr.*, 11 (1936), No. 6, pp. 551-572, fig. 1).—In this study at the Illinois Experiment Station, three groups of rats each consisting of 11 or 12 pairs were fed by the paired feeding method. During a preliminary period pairs in group 1 received rations containing 0.18 and 1.25 percent of calcium, pairs in group 2, 0.32 and 1.25 percent, and pairs in group 3, 0.49 and 1.25 percent of calcium. At the end of this period three or four pairs in each group were sacrificed for chemical analyses and the remaining pairs in all groups were fed at the 1.25-percent level until they

attained a weight of 200 g (regardless of the time required to attain this weight), when all were sacrificed for measurements and analyses.

From the data reported it is concluded that the calcium content of growing rats is dependent not only on the calcium content of the diet but also on the rate of growth, which is largely determined by the rate of food consumption. The coefficient of correlation between rate of growth and calcium content of the carcass is found to be  $-0.929 \pm 0.013$ . This inverse relationship is attributed to the tendency for rapid growth to be associated with (1) slow calcification of the bones and (2) a high ratio of soft tissue to skeletal tissue. Very low levels of calcium in the diet retarded growth not only during the consumption of such a diet but also during the subsequent period of adequate calcium supply.

Differences in the percentage of calcium in the carcasses of various groups at the end of the preliminary period and differences in rate of retention during the subsequent feeding at a high level indicate that the rate of calcium retention by growing animals under conditions of adequate nutrition measures the day-to-day requirement for calcium only when the calcium stores have been saturated by appropriate prefeeding. Otherwise, the observed calcium retentions will be greater than the daily requirements.

**A study of the magnesium needs of preschool children**, A. L. DANIELS, G. J. EVERSON, ET AL. (*Jour. Nutr.*, 11 (1936), No. 4, pp. 327-341, figs. 2).—Thirty-three calcium, phosphorus, and magnesium balance studies were performed on 10 boys and 3 girls, ages from 4 to 7 yr. The details of the procedure have been reported in a previous study (E. S. R., 75, p. 882).

The magnesium ingestions varied from 11.3 to 19 mg per kilogram, and the retentions ranged from 0.4 to 3.1 mg per kilogram. The urinary magnesium tended to parallel the magnesium ingestion, and it is suggested that this might be taken as an indication of an adequate magnesium ingestion. The calcium:magnesium ingestion ratios ranged between 2.8 and 6.7 and the calcium:magnesium retention ratios between 3.8 and 30.3, with no relationship between the calcium and magnesium retentions or between the magnesium retentions and the calcium:magnesium ingestions. Of the children studied, 75 percent showed high urinary magnesium, with high retentions following high ingestions of magnesium. "It was concluded tentatively that diets of children of the ages studied should contain not less than 13 mg per kilogram of body weight."

**Cholesterol metabolism in children with and without endocrine dysfunctions**, M. MOLITCH and S. POLIAKOFF (*Arch. Ped.*, 53 (1936), No. 9, pp. 613-616).—The subjects were boys aged from 8 to 18 yr. who were inmates of an institution. Approximately 25 percent were found to have some type of endocrine dysfunction.

The total serum cholesterol was determined by a modification of the Sackett method (E. S. R., 54, p. 10). The daily diet included 1 qt. of milk and at least one serving of meat. To test the influence of diet on the cholesterol content, 47 boys were placed on a high fat-high cholesterol intake for 2 weeks by adding to the daily diet  $\frac{1}{2}$  lb. of meat organs or several eggs. The average rise in serum cholesterol was 12 mg per 100 cc above the level before the special diet was given. It appeared that the serum cholesterol depended to a certain extent upon the fat and cholesterol contents of the diet.

The control group consisted of 284 normal boys. Its total serum cholesterol was found to range from 81 to 204 mg per 100 cc, with 85 percent of the group between 100 and 160 mg per 100 cc and the average 130.7 mg. The 157 subjects with endocrine dysfunction, with one exception, showed a range of total serum cholesterol between 81 and 200 mg per 100 cc, with 79 percent of the group between 100 and 160 mg and 91 percent between 100 and 180 mg per 100 cc.

These values were within the normal range of total serum cholesterol. The authors confirmed Rothbart's findings (E. S. R., 73, p. 879) in that no correlation was found between total serum cholesterol, basal metabolism, and mental level.

**Cytophysiological study of the action of vitamin A** [trans. title], P. JOYET-LAVERGNE (*Bul. Soc. Chim. Biol.*, 18 (1936), No. 6, pp. 1041-1054).—The author reviews the cytophysiological studies on vitamin A and summarizes the results of his investigations on the presence of vitamin A in the nucleolus and chondrioma of plant and animal cells. When vitamin A is lacking, cell multiplication ceases and growth is limited, showing that vitamin A is a growth factor. The role of vitamin A in metabolism appears to be that of an independent factor in catalysis. The manifestations of avitaminosis A are attributed to its indispensable function as catalyst of oxidation and reduction processes.

**Changes in the vaginal epithelium of the rat on an excessive vitamin A diet**, T. C. SHERWOOD, M. A. BREND, and E. A. ROPER (*Jour. Nutr.*, 11 (1936), No. 6, pp. 593-597).—A group of 18 female rats 150 days old receiving a complete diet was examined at 8-hr. intervals for the normal vaginal smear content until 8 complete oestrous cycles had been determined. The animals then received as supplement 1,500 international units of carotene daily for 15 days. The vaginal smear technic was continued during and following carotene administration until 8 normal oestrous cycles had again been observed. This procedure was repeated with another group of 16 female rats 150 days old receiving 3,750 international units of carotene daily for the 15-day period.

Examination of the vaginal smear picture showed no deviation from normal in the control rats receiving the normal diet, with or without the addition of cottonseed or corn oil. Following carotene administration to the experimental animals, abnormality was apparent within 2 days. Nucleated epithelial cells predominated at all stages of the oestrous cycle, and leucocytes were continuously present, while the cornified cells were rare or absent. The cycle did not return to normal until 20 days after cessation of the carotene feeding.

**Lesions of the nervous system in vitamin deficiency.—IV, The effect of carotene in the treatment of the nervous disorder in rats fed a diet low in vitamin A**, H. M. ZIMMERMAN and G. R. COWGILL (*Jour. Nutr.*, 11 (1936), No. 5, pp. 411-423, figs. 2).—Continuing an earlier study (E. S. R., 69, p. 311), young rats were maintained from weaning on an artificial diet deficient in vitamin A but containing hydrogenated vegetable oil and linoleic acid. Some animals received prophylactic doses of carotene, others received curative doses, and the remainder were fed the vitamin A-deficient diet without supplement. Tests were employed to study evidences of neurological manifestations, and at post mortem the sciatic nerves, brachial plexuses, spinal cord, and cerebrum were examined microscopically.

The results obtained in the previous study were confirmed by this investigation, i. e., "that rats subsisting on an artificial ration low in vitamin A often develop neurologic manifestations of disease which are due to demyelination of the peripheral nerves and spinal cord." The administration of carotene in inadequate dosage of 50  $\mu$ g (micrograms) given late in the course of the deficiency did not prevent the occurrence of the neurological symptoms and death. The animals receiving an adequate dosage of carotene, 100  $\mu$ g, relatively early in the course of the deficiency were restored to good health, with the neurologic disorder persisting to an even more marked degree than in the untreated animals. The daily administration of 50  $\mu$ g of carotene throughout the experiment was effective in preventing the development of the nervous disorder, but since the presence of linoleic acid in the diet did not prevent it, vitamin A

rather than the presence or absence of unsaturated fatty acids is evidently the factor.

[**The physiological mechanism of avitaminosis A**] (*West Virginia Sta. Bul.* 278 (1936), pp. 27, 28).—This progress report (E. S. R., 72, p. 728) deals with the water metabolism of rats and of dogs (E. S. R., 75, p. 727) in vitamin A deficiency.

**The vitamin-B and -G content of commercial beer**, P. B. DONOVAN and M. E. HANKE (*Soc. Expt. Biol. and Med. Proc.*, 33 (1936), No. 4, pp. 538-543).—Five samples of commercial beer, three of which were advertised as a source of vitamins, were fed at dose levels ranging from 2.5 to 30 cc per day. The experimental animals were 21-day-old rats depleted of the vitamin B complex for 2 weeks following weaning and before being placed on the test doses.

The results, based on rat growth and survival when 0.4 g of dried yeast or the beer supplements were fed, show that pasteurization did not affect the vitamin B complex concentration. Filtration through sintered glass did not appreciably change the vitamin content, whereas filtration through paper caused a loss of some vitamin B and nearly all of the vitamin G. When the three beers which were advertised as a source of vitamins were fed at the 10-cc level, the rats showed approximately 50 percent more growth than was shown by the rats receiving other beers.

That the limiting factor in the growth of rats receiving beer supplements is vitamin B was shown by feeding B extract containing a minimal amount of vitamin G and autoclaved yeast containing a minimal amount of vitamin B. The addition of vitamin B extract increased the growth rate to the level attained by the positive control rats, a level not reached when autoclaved yeast was fed. The approximate concentration of vitamin B in the beers tested was calculated to range from 0.05 to 0.1 Sherman unit per cubic centimeter. The concentration of vitamin G was considerably greater. These results show that beer is a wholly inadequate source of vitamin B for the rat.

**The B-vitamins in human urine**, M. H. ROSCOE (*Biochem. Jour.*, 30 (1936), No. 6, pp. 1053-1063, fig. 1).—During a period of 12 days on an ordinary hospital diet, with and without the addition of a known amount of vitamin B complex, the amounts of vitamins B<sub>1</sub> and B<sub>2</sub> in the urine of three normal subjects and one case of "alcoholic" polyneuritis were estimated by methods similar to that of Harris et al. for vitamin C (E. S. R., 72, p. 568). The total urine for each subject during each period was concentrated to 1 l and fed to rats deprived of vitamin B<sub>1</sub> or B<sub>2</sub>, respectively. The vitamin B<sub>1</sub> activity was estimated by a curative method and the vitamin B<sub>2</sub> activity by a growth method, using rats as the experimental animal.

No vitamin B<sub>1</sub> could be found in the urines of subjects receiving the ordinary hospital diet. When 720 international units of vitamin B<sub>1</sub> daily were added to the diet, 167-333 international units of the vitamin were excreted in the urine and the remainder of the additional intake was assumed to have been retained. When the subjects were receiving the hospital diet, small quantities of vitamin B<sub>2</sub> were present in the urines. The addition of supplementary vitamin B<sub>2</sub> caused increased excretion and apparently increased retention. In the case of the alcoholic polyneuritic the initial amount of the vitamins excreted was comparable with that of the normal subjects. When additional vitamins were given, the vitamin B<sub>1</sub> retention appeared to be slightly less and the vitamin B<sub>2</sub> retention slightly greater than those observed in the normal subjects.

**Role of adenylic acid in vitamin B<sub>2</sub> deficiency**, T. W. BIRCH and L. W. MAPSON (*Nature [London]*, 138 (1936), No. 3479, pp. 27, 28, fig. 1).—The action of adenine nucleotides on the heart of both the normal and the vitamin B<sub>2</sub>-

deficient animal was studied. It was found that the bradycardia present in rats deficient in vitamin B<sub>1</sub> was increased when adenosine or adenylic acid from muscle or yeast was injected. A much smaller effect was produced in normal animals. "These results suggest that the B<sub>1</sub>-deficient animal is unable to render these compounds innocuous at the same rate as does the normal animal." The authors have established the fact that deaminase activity of vitamin B<sub>1</sub>-deficient cardiac tissue is approximately 20 percent lower than that of similar tissue from animals adequately fed. The deaminase activity became normal in 18 hr. after the administration of vitamin B<sub>1</sub>. All attempts to obtain this restoration by the direct addition of vitamin B<sub>1</sub> to deficient tissue in vitro have been unsuccessful. This failure of the deaminase mechanism may result in the increased accumulation of adenylic acid in the tissue, which is the cause of bradycardia. Other effects obtained with vitamin B<sub>1</sub>-deficient tissue, such as increased lactic acid and decreased oxygen consumption, may be due to the inhibition by adenylic acid of the oxidative mechanisms which are responsible for the removal of the metabolites.

**Successful treatment of human pellagra with the "filtrate factor",** P. J. FOUTS, S. LEPKOVSKY, O. M. HELMER, and T. H. JUKES (*Soc. Expt. Biol. and Med. Proc.*, 35 (1936), No. 2, pp. 245-247).—In this preliminary report the results are summarized of the treatment of 4 pellagrins on a pellagra-producing corn diet with concentrates of various factors of the vitamin B complex.

No improvement was noted following continued treatment of two of the patients with 10 and 20 mg, respectively, daily of lactoflavine, but when this was replaced by 6 vials daily of liver extract (derived from 600 g of liver) there was rapid improvement in all of the symptoms. The treatment of a third patient with 35 cc daily of the concentrate of the filtrate factor (chick antidermatitis) of Lepkovsky et al. noted on page 839 was followed by very marked improvement. After 10 days the mouth was normal, there was no diarrhea, and only an increase in pigmentation of the skin over the involved parts remained of the dermatitis. The fourth patient, who had severe polyneuritis in addition to the pellagic symptoms, was given 20 cc daily of a concentrate of vitamin B<sub>1</sub> prepared as described by Stuart et al. (*E. S. R.*, 72, p. 443). After 4 days the general condition had improved and the caloric intake had increased, but the dermatitis, diarrhea, and stomatitis grew worse. The filtrate factor was then administered daily in 50-cc doses, with complete disappearance of the diarrhea in 3 days and rapid improvement in the dermatitis and stomatitis.

"Pellagrins can be cured while on a maize diet by the administration of a liver filtrate which contains the chick antidermatitis factor but which is free from lactoflavine and rat vitamin B<sub>6</sub>."

**Vitamin sources, XVIII, XIX** [trans. title], T. L. ISUMUDOWA (*Ztschr. Untersuch. Lebensmit.*, 71 (1936), No. 4, pp. 324-330).—Two papers are presented.

**XVIII. Antiscorbutic concentrates from sorrel** (pp. 324-326).—Guinea pigs were protected from scurvy when 0.3 g of sorrel juice, acidified to pH 2.90-2.99 with hydrochloric acid, was fed daily. Signs of scurvy were evident in animals receiving the sorrel juice without added hydrochloric acid. From the results of biological tests it was estimated that 1 kg of the acidified concentrate contained 3,000-5,000 units of vitamin C. Applying the Tillmans titration method, values of 2,100-2,200 units per kilogram were obtained.

**XIX. The effect of freezing on the antiscorbutic activity of potatoes** (pp. 326-330).—Biological tests were made on groups of guinea pigs with two varieties of potatoes. The results show that storage of the potatoes at temperatures of from -13° to -16° C. preserved the vitamin C content, 1 kg

containing at least 166 units. Potatoes stored at a temperature not lower than from 2.5° to 3° showed a loss of antiscorbutic potency. In tests made on the cooked potatoes it was found that slightly greater loss of antiscorbutic potency resulted when the frozen potatoes were immersed in cold water before cooking than when hot water was used. The animals receiving 0.6 g daily of frozen potatoes which had been immersed in hot water before cooking were protected from scurvy.

The preceding paper in the series is by Jarussowa (E. S. R., 75, p. 571).

**Distribution of vitamin C in different parts of common Indian foodstuffs,** M. N. RUDRA (*Biochem. Jour.*, 30 (1936), No. 4, pp. 701-703).—The ascorbic acid content of different parts of various Indian fruits and vegetables and a few animal foods was determined by the indophenol method. In the fresh and young fruits and vegetables the ascorbic acid was more concentrated in the skin than in the flesh, but this was reversed when the food had been stored or dried. Various organs and tissues of the goat gave the following values: Liver 0.263 mg per gram, kidney 0.176, bone marrow 0.088, milk 0.085, heart 0.077, and muscle 0.66 mg per gram.

**The vitamin C content of human milk and its variation with diet,** I. SELLEG and C. G. KING (*Jour. Nutr.*, 11 (1936), No. 6, pp. 599-606).—Values obtained by the indophenol titration technic, as described by Bessey and King (E. S. R., 71, p. 137), are given for the vitamin C content of human milk. Orange juice providing varying amounts of vitamin C per day was given to some groups of patients, the remainder receiving the good hospital diet without supplement.

The vitamin C content of human milk determined in the 53 patients at the beginning of the experiment varied from 0.012 to 0.108 mg per cubic centimeter, the average being 0.055 mg. The patients without orange juice supplement showed a gradual rise in the average value of vitamin C to reach 0.064 mg per cubic centimeter of milk on the tenth day post partum. The corresponding values for the two groups receiving orange juice supplement equivalent to 210 and 430 mg of vitamin C per day rose to 0.073 and 0.081 mg. The range of vitamin C was approximately 0.06-0.08 mg per cubic centimeter of milk when the mother was receiving an adequate diet. This indicates that the normal requirement of vitamin C per day for an infant may be established from the amount supplied in mother's milk when the diet of the parent is adequate. Under optimum conditions, with a fluid intake of 21 oz., a child might receive from 40 to 50 mg of vitamin C daily in the first few weeks of life.

**Quantity of vitamin C necessary to maintain the normal reducing value of animal tissues** [trans. title], D. DE CABO (*Hoppe-Seyler's Ztschr. Physiol. Chem.*, 240 (1936), No. 3-4, pp. 179-190, fig. 1).—The adrenals of guinea pigs maintained on a vitamin C-free diet were studied. The content of vitamin C in the tissues was determined at various stages during the development of scurvy and the curative period by titration with 2,6-dichlorophenolindophenol. The rate of disappearance of vitamin C from the adrenals was found to be roughly represented by an exponential curve.

Injectations were more potent than oral administrations in maintaining the normal concentration of ascorbic acid in the adrenals and liver. Larger amounts than the ordinary protective dose against scurvy were required. More effective results were obtained when the oral administration was given as a natural constituent of the food than in aqueous solution.

The injection of 12 mg of isoascorbic acid gave similar results to those obtained by injections of 5 mg of ascorbic acid in protecting the guinea pigs and maintaining the normal reducing power of the adrenals. It is suggested

that the presence of ascorbic acid in normal concentration in the tissues provides a necessary condition for optimum cell activity rather than acting as a reserve.

**Vitamin-C deficiency in Addison's disease**, J. F. WILKINSON and C. A. ASHFORD (*Lancet [London]*, 1936, II, No. 17, pp. 967-970).—Three women patients with Addison's disease were shown to be suffering from vitamin C subnutrition when diagnosed by the method of Harris and Ray (*E. S. R.*, 73, p. 427). The degree of subnutrition ran parallel to the severity of the symptoms. The possible significance of the finding and the relationship of vitamin C to pathological pigmentation are discussed.

**Experiments confirming the antiscorbutic activity of dehydroascorbic acid and a study of its storage and that of ascorbic acid by the guinea-pig at different levels of intake**, F. W. FOX and L. F. LEVY (*Biochem. Jour.*, 30 (1936), No. 2, pp. 211-217, fig. 1).—Young guinea pigs were placed on the scurvy-producing diet described by Bracewell et al. (*E. S. R.*, 64, p. 497) supplemented by dehydroascorbic acid, which was prepared from orange juice treated with norite. At the end of the 14-week experimental period, scurvy was not present in any of the test animals. One animal born during the experiment was successfully reared on the diet with oxidized vitamin supplement.

Following the method of Birch et al. (*E. S. R.*, 70, p. 741), the amount of antiscorbutic vitamin in the livers and adrenals of the animals was estimated. It was concluded that the guinea pig has a small and definite capacity for storing the vitamin in the liver and that dehydroascorbic acid is not as easily stored as ascorbic acid. Further experiments to determine the ascorbic acid content of the liver and adrenals of guinea pigs killed after 10 days on the scorbutic diet showed that the amount of ascorbic acid stored is closely dependent upon the actual level of intake.

**Rachitogenic factors in cereals** [trans. title], O. RYGH (*Bul. Soc. Chim. Biol.*, 18 (1936), No. 6, pp. 1091-1096).—The vitamin D content of oats was determined by the method of Poulsson and Lövenskiöld (*E. S. R.*, 59, p. 293). The fat was extracted from the oats, saponified, and the fatty acids recovered from the saponified fraction. The unsaponifiable fraction contained approximately 880 international units of vitamin D per gram, which was equivalent to 6 international units per gram of whole oats. The fatty acids from the saponifiable fraction were found to be actively rachitogenic. The fatty acids derived from the fat of green plants exhibited antirachitogenic activity and when fed to the test animals receiving doses of fatty acids derived from oats the rachitogenic effect was neutralized. When sufficient caustic soda was added to partially neutralize the fatty acids from oats, the unneutralized portion became more potently rachitogenic. Fractional distillation destroyed the rachitogenic action of the fatty acids.

**Effects on the fetus of hypervitaminosis D and calcium and phosphorus deficiency during pregnancy**, L. W. SONTAG, P. MUNSON, and E. HUFF (*Amer. Jour. Diseases Children*, 51 (1936), No. 2, pp. 302-310, fig. 1).—This is an investigation of the relationship between abnormalities of the intake of minerals and vitamin D by the mother and mineralization of the rat fetus. The experimental animals were eight litters of 30 virgin rats maintained on a modified Sherman B diet. The animals were bred and following conception were subjected to one of four procedures: A control group received the stock Sherman diet during pregnancy; group 2 received a diet deficient in calcium, phosphorus, and vitamin D; group 3 received the deficient diet supplemented by 0.2 cc of viosterol 2,700 D; group 4 received the deficient diet supplemented by graded doses ranging from 0.08 to 0.15 cc of viosterol. Immediately after parturition the newborn rats were killed, weighed, and ashed, and calcium and phosphorus

determinations were made. Roentgenograms were made of the rat mothers immediately after conception and after parturition.

The data, based on findings with 19 litters, demonstrate that the offspring of rats that received a diet deficient in calcium and phosphorus had a lower calcium and phosphorus content than the offspring of the control rats. The calcium and phosphorus contents of the offspring were not increased by the administration of high doses of vitamin D to the rats receiving the mineral-deficient diet during gestation. The weight of the offspring was decreased when vitamin D, calcium, and phosphorus were lacking in the mother rat's dietary. The offspring of rats on the deficient diet, with and without vitamin D, showed a higher calcium : phosphorus ratio than did the offspring of the rats receiving graded doses of vitamin D, or the control rats. The experiment indicates that the mineral content of the offspring is dependent upon the mineral metabolism of the rat mother.

The success of treating celiac disease from a standpoint of vitamin deficiency, C. V. RICE (*Arch. Ped.*, 53 (1936), No. 9, pp. 626-629, figs. 2).—The author reports the successful treatment of celiac diseases in three children by a dietary regime containing high vitamin sources. A detailed account of one case is given. The diet included fat in the form of evaporated milk, sugar as wheat germ sugar, and vitamin concentrates.

Note on the non-identity of lactoflavin and the "extrinsic factor" in pernicious anaemia, C. A. ASHFORD, L. KLEIN, and J. F. WILKINSON (*Biochem. Jour.*, 30 (1936), No. 2, pp. 218-223).—In continuation of the series of papers noted previously (E. S. R., 73, p. 889), the authors studied the hemopoietic activity of lactoflavine. Three human subjects failed to respond to parenteral administration of lactoflavine alone or incubated with the fraction P 5 [the active fraction prepared by alcoholic precipitation of the press juice from hog's stomach] (E. S. R., 71, p. 140), or to the intramuscular administration of lactoflavine incubated with normal gastric juice. These results show that lactoflavine is neither the liver antipernicious anemia principle nor the extrinsic factor concerned in hemopoiesis.

The anemia of deaminized casein, M. I. SMITH and E. F. STOHLMAN (*Pub. Health Rpts. [U. S.]*, 51 (1936), No. 24, pp. 772-786, figs. 7).—The authors describe a series of feeding experiments showing that the anemia of deaminized casein, as described by Hogan and Ritchie (E. S. R., 72, p. 892), is an intoxication and not a deficiency disease. Groups of rats were placed on a diet in which deaminized casein was the sole protein source, one in which lysine, tyrosine, and histidine had been added in amounts approximately equivalent to those present in casein when fed at the optimum level of 18 percent, and diets supplemented with 5 and 12 percent dried brewers' yeast, 5 percent casein and 5 percent dried brewers' yeast, and 15 percent casein and 5 percent dried brewers' yeast. None of the experimental animals was completely protected from anemia. Treatment with liver extract of a group of anemic rats appeared to have no effect on the blood picture and no influence in arresting the progress of the anemia. The experiments indicated that in animals receiving a diet containing adequate protein in addition to the deaminized casein the red blood cells and hemoglobin did not fall so rapidly nor to as low a level as they did in the less adequately supplemented diets. The authors interpret the results as follows: "First, the nutritive value of deaminized casein is low or nil; second, deaminized casein appears to contain an unidentified toxic factor highly specific for the blood elements."

A residue was prepared from deaminized casein by suspending 25 g of deaminized casein in 400 cc of methyl alcohol containing 6-7 cc of 9 N sodium hydroxide in an Erlenmeyer flask, refluxing in a water bath at 72°-75° C. for

$\frac{1}{2}$  hr., filtering, washing with methyl alcohol and with ether, and drying. This residue fed at a level of 10 percent as the sole source of protein was wholly inadequate when judged by weight curves and periods of survival, but no evidence of anemia could be found. A group of rats fed 5 percent of yeast protein in the form of 12 percent of dried brewers' yeast demonstrated a moderate degree of anemia. In another group on a diet in which 15 percent of casein was included in addition to the "detoxified" deaminized casein only one of seven rats had a red cell count and hemoglobin slightly below normal. "These results seem to prove conclusively that the anemia-producing and growth-inhibiting factor or factors of deaminized casein are to a large extent removed or destroyed by boiling with alkaline methyl alcohol."

An extract of the detoxified product was distilled in vacuo, and the residue was taken up in a small amount of water, neutralized with hydrochloric acid, dried on starch, and incorporated at a level corresponding to 10 percent of deaminized casein in a ration containing 12 percent of dried brewers' yeast as the sole source of protein for 3 weeks and 6 percent for the following 3 weeks. Both rats on the experiment showed a normal blood picture at the end of the period. "It may be concluded . . . that the hematotoxic factor in the deaminized casein had not been extracted but was largely destroyed by boiling with alkaline methyl alcohol."

When detoxified deaminized casein, reprecipitated by HCl and filtered, was fed to one group of rats and the filtrate concentrated to a small volume was injected into another group, none of the animals developed anemia.

In order to identify the toxic substance, various extracts of deaminized casein were prepared and their effects on the blood picture were studied. The only way to recover the toxic factor was by rather drastic hydrolysis of the deaminized casein with hydrochloric acid. The residue so obtained produced anemia when tested in rats. "This would seem to indicate that the toxic factor is so firmly bound to the protein molecule that it could not be liberated without the more or less complete disintegration of the protein." Three preparations of partially active hydrochloric acid hydrolysates of deaminized casein are described which, when injected intraperitoneally in rats, produced the morphologic changes in the blood picture of the majority of the animals, thus furnishing conclusive evidence of the toxic nature of the anemia of deaminized casein.

## TEXTILES AND CLOTHING

A series of technical studies on unweighted and weighted silk, I-V (*Rayon and Melliand Textile Mo.*, 16 (1935), No. 12, pp. 39-41, 48, fig. 1; 17 (1936), Nos. 1, pp. 49-53, figs. 5; 2, p. 66, figs. 3; pp. 67, 68, figs. 4; 3, pp. 36-38, figs. 2; 4, pp. 72, 73, fig. 1; 5, pp. 35, 36, figs. 4; 6, pp. 65, 66, fig. 1).—The following papers are taken from the report of a series of 12 studies on unweighted and weighted silks made at the Pennsylvania State College:

I. *The effect of the tin-weighting process on the strength of new silk*, W. M. Forbes and P. B. Mack (pp. 39-41, 48).—Three series of tests were made on silk fabrics prepared from satin-faced crepe. In series 1, one sample was unweighted while the other five were passed from one to five times through a stannic chloride-disodium phosphate bath. In the same manner the samples of degummed silk in series 2 and 3 were weighted without being given a commercial finishing. To determine the degree of weighting the samples were immersed successively in water at 65° C., alcohol and ether, 2 percent hydrofluoric acid at room temperature, and 2 percent sodium carbonate at 65°. The percentage content of the material other than fibroin, the mineral weighting,

and the ash values were obtained. The effects of weighting on the strength of the new silk were studied by testing the breaking strength, bursting strength, tear resistance, and abrasion resistance.

The results show that with increased weighting the breaking strength and the ability to withstand tear resistance were decreased. The abrasion-resistance test showed that after 1,000 rubs on the testing machine the weighted samples were less resistant to tearing strain. The unweighted silks resisted breakage after 2,000 rubs, while the weighted samples ruptured, the greatest damage being noted in the more heavily weighted silks.

II. *A study of the effects of light and air on unweighted and tin weighted silk*, N. M. Roberts and P. B. Mack (pp. 49-53).—Using samples of the same silk fabrics as in the above study, and others of a similar weave, the weighting process was carried out by two different methods. The weighting determinations and physical tests were made as above. Further tests were done to determine the effects of aging in the absence of light, in indoor daylight, by irradiation with a sunlight (S-1) lamp, and in evacuated tubes in the dark.

The weighted samples to which a commercial dressing had been applied were considerably lower in breaking strength than were the undressed samples of about the same percentage of weighting. Although the loss in breaking strength after aging was not as great as in the dressed silks, this saving in durability did not compensate for the loss in breaking strength. Aging for 6 mo. in the dark produced slightly greater losses in breaking strength in the unweighted and lightly weighted samples than was produced by irradiation for 100 hr. with a sunlight lamp. In the heavily weighted samples the greatest loss was produced by irradiation in the air and in evacuated clear quartz tubes, with less loss after storage in the dark. In the unweighted and lightly weighted samples less loss in breaking strength was produced by 100 hr. of irradiation than by 4 months' exposure to indoor daylight.

III. *The effect of darkroom storage on unweighted and tin weighted silk*, A. A. D'Olier and P. B. Mack (p. 66).—Tests were made on the same fabrics as above to determine the effect of from 6 to 31 mo. of darkroom storage on the breaking strength of the silks. The results show that the breaking strength decreased progressively as the percentage content of a weighting material increased and was greater in the samples to which a commercial dressing had been applied.

IV. *The effect of tin weighting on the air permeability of silk*, N. M. Roberts and P. B. Mack (pp. 67, 68).—Previously noted (E. S. R., 67, p. 781).

V. *The effect of drycleaning and of water washing on the strength of unweighted and of tin weighted silks, parts 1-4*.—This presents the subject matter in four parts, as follows:

Part 1. *The effect of drycleaning, stains, stain removal agents, and pressing*, E. C. Ramsay and P. B. Mack (pp. 36-38).—Silks from the same bolts as in the previous studies but with different amounts of weighting were used. The standard procedure for cleaning silks was repeated from 1 to 15 times on each fabric. Nine representative types of stains were applied in studying the effect of the stain alone, the stain and the removal reagent, and the reagent alone. The fabrics were ironed with an electric hand iron, a steam-heated flatwork iron, and a hand steam iron. One of each series of fabrics after 15 dry cleanings was pressed with a hand steam iron.

Dry cleaning alone produced very little effect upon the breaking strength of the fabrics. The stains and spotting reagents of an acid character had a tendency to reduce the breaking strength in both unweighted and weighted fabrics, the action being more apparent in the latter group. Oily stains and

volatile spotting agents showed very little effect, but serious loss of breaking strength was noted when fountain pen ink, mercurochrome, rust, perspiration, tannin, black carbon ink, iodine, and blood were allowed to remain on the fabric for 3 weeks. Spectroscopic examination revealed that the tin was removed from the tin-silk combination in the weighted silk by the acid present in the stain or removal agent.

In the pressing process the new silk was more tender following the application of dry heat than moist heat. The steam-heated flatwork ironer had less tendering effect than the steam hand iron. The fabrics which had been dry-cleaned before pressing did not show any greater losses in breaking strength.

**Part 2. *The effect of various drycleaning solvents on unweighted and on tin weighted silks*, M. D. Hale and P. B. Mack (pp. 72, 73).**—In cleaning a typical pure-dye flat crepe silk containing 5.9 percent dressing and a tin weighted sample containing 55.48 percent dressing and weighting there were used carbon tetrachloride, trichloroethylene, perchloroethylene, Dow Solvent 68, and orthodichlorobenzene. The fabrics were dry cleaned for 25 min. by the following methods: (1) Predried for 1 hr. in an 85° C. drying oven and cleaned with solvent alone, (2) humidified in an atmosphere of 100 percent relative humidity for 1 hr. and cleaned in solvent alone, (3) preheated for 1 hr. and cleaned with solvent to which 2.5 percent of anhydrous potassium oleate soap had been added, and (4) humidified and cleaned with the solvent and soap. The fabrics were all brought to constant weight in an 85° oven before the breaking strength measurements were made.

Predrying caused only slight losses in breaking strength, and the pure-dye silks showed less losses than the tin-weighted silks. When soap was used, slightly greater losses were shown by the pure-dye silks, with only slight differences noted in the weighted silks. All of the synthetic solvents tested caused losses greater than 40 percent when soap was used and the fabrics were pre-humidified, as compared with approximately 20 percent losses when the fabrics were predried.

**Part 3. *Practical drycleaning trials of miscellaneous silks*, C. It. Phillips and P. B. Mack (p. 73).**—To determine how weak silk fabric need be in order to break during the commercial dry-cleaning process, the breaking strengths of 18 silk fabrics in varying stages of aging were measured before and after the dry-cleaning process. The fabrics were dry cleaned for 25 min. in a commercial machine, using Stoddard Solvent and 2.5 percent of anhydrous potassium oleate soap, followed by a 15-min. rinse in clear solvent.

The resulting losses in breaking strength varied from 0 to 19.8 percent, with rupture occurring only when the initial strength in the weaker direction was very low. More satisfactory results were obtained in dry cleaning the pure-dye silk fabrics than the weighted silk, spun silk, or silk fabrics with discharge printed designs which had been aged.

**Part 4. *The effect of water-washing upon the strength of unweighted silks*, B. Cohen and P. B. Mack (pp. 35, 36, 65, 66).**—The six fabrics tested were those described in paper 1 as a graduated series with respect to the degree of weighting. The following treatments were administered: (1) Soaking in distilled water for 2, 7, 12, and 24 hr. at 18°, (2) soaking in distilled water for 2 hr. at 18°, 38°, 50°, and 100°, (3) soaking for 7 hr. at room temperature in distilled water containing 8 grains each of hardness from both calcium carbonate and magnesium sulfate, (4) soaking in distilled water for 2 hr. at 50°, containing various kinds of soap, and (5) washing for 2 hr. at 50° by various home methods. In addition 11 miscellaneous weighted and unweighted silks were laundered in one commercial and two home electric washers.

The strength losses became progressively greater as the time of soaking was increased, and were greatest in fabrics of intermediate degrees of weighting. After the 2-hr. soaking period the least losses were shown in the most heavily weighted silks and the pure-dye silks. However, with longer soaking periods, these fabrics showed proportionately greater percentage of shrinkage than the intermediate weighted fabrics. The losses increased as the temperature of the water was increased, with the heavier weighted fabrics showing the lowest loss at 18°. Shrinkage increased only slightly with temperature increases and was greater at all temperatures for the fabrics of intermediate weighting content. Soaking in distilled water caused smaller losses than in hard water, with the fabrics of the lowest weighting content showing the greatest losses in the hard water. Excessive strength losses and shrinkage resulted in all fabrics soaked in water containing alkaline soap with and without rosin. Neutral soaps and water caused strength losses and shrinkage slightly less than that caused by distilled water.

The mechanical action tests demonstrated that greater tendering effect and shrinkage resulted from rubbing the fabric between the knuckles, squeezing between cupped hands, and rubbing on the washboard. Washing with the vacuum type of washing machine produced the least tendering effect except with the most heavily weighted fabrics, which showed the best results after the process of squeezing with the cupped hands.

The losses in breaking strength of the miscellaneous silks increased with increases in weighting. No definite trends could be demonstrated for shrinkage tests because the fabrics were of different weaves. Generally, the strength losses of all fabrics were practically the same for the commercial washer and the two types of home washing machines.

**A modified method for measuring wool damage due to scale breakage,** J. H. KETTERING (*Jour. Home Econ.*, 28 (1936), No. 4, pp. 255-259, fig. 1).—This test, as developed in the U. S. D. A. Bureau of Home Economics, is used to determine accurately the extent to which undyed fibers or fabrics have been damaged during the manufacturing process or subsequent service, and it also indicates the amount of service a fabric may be expected to give. The method, which is a modification of the Rimington-Pauly test, is as follows:

"To a mixture of 10 cc of 10-percent sodium sulfanilate and 5 cc of 8-percent sodium nitrite, add 2 cc of concentrated hydrochloric acid, shake gently, and let stand for 1 min. Then add this mixture to 15 cc of 9-percent sodium carbonate solution which contains a 0.1-g sample of the wool weighed under standard conditions, and allow to stand exactly 10 min. Remove sample, wash it in a sintered glass crucible with 300 cc distilled water, and dry it on a watch glass in a dark room. When dry add the sample to 50 cc of 2 N sodium hydroxide and allow to stand for 18 hr. Shake well and compare this solution with 0.1 percent New Acid Brown S, using colorimeter and artificial light." The dye solution should be prepared the previous day and filtered immediately before use. The reactions should be performed in a constant temperature laboratory kept at 70° F.  $\pm 1^\circ$ , and all solutions should be brought to that temperature before beginning the test.

Using this modified procedure, reproducible results were obtained from fabrics both slightly and extensively damaged. The values obtained were correlated to the strength index and showed a linear relation existing between the results of the revised test and of a physical measure of deterioration.

**Guides for buying sheets, blankets, and bath towels,** B. M. VIEMONT, M. B. HAYS, and R. O'BRIEN (*U. S. Dept. Agr., Farmers' Bul. 1765* (1936), pp. [2]+28, figs. 10).—This presents guides to aid the housewife in judging the

durability and drying qualities of bath towels, such as knowledge of the length and width of the towel, the colorfastness, the amount and rate of water absorption, the number of filling and warp yarns to the inch and their breaking strengths, the weight per square yard, and the number of square inches of terry in the entire towel. Revisions of the material as to sheets and blankets contained in Leaflet 103 (E. S. R., 71, p. 142) and Leaflet 111 (E. S. R., 73, p. 573) are also included.

### MISCELLANEOUS

**An outline of biometric analysis, A. E. TRELOAR** (*Minneapolis: Burgess Pub. Co., 1936, [2. ed.], pp. [12]+193, figs. [44]*).—This outline "has in view the aiding of students in grasping the fundamentals of courses in biometric analysis, given by the author at the University of Minnesota, and its contents are entirely limited by the demands of that teaching."

**Partners in agricultural progress: [Biennial Report of California Station, 1935-36], C. B. HUTCHISON and S. G. RUBINOW** (*California Sta. [Bien.] Rpt., 1935-36, pp. IX+230, pls. 23*).—The experimental work not previously referred to is for the most part noted elsewhere in this issue.

**Report of the Hawaii Agricultural Experiment Station, 1936, [O. C. MAGISTAD ET AL.]** (*Hawaii Sta. Rpt. 1936, pp. 96, figs. 16*).—The experimental work not previously referred to is for the most part noted elsewhere in this issue.

**Index to Vols. 1-18 (inclusive)** (*Michigan Sta. Quart. Bul., 1936, Index vols. 1-18, pp. 68*).—This includes both subject and author indexes.

**Farm Research, January 1, 1937** (*Farm Res. [New York State Sta.], 3 (1937), No. 2, pp. 14, figs. 6*).—In addition to papers noted elsewhere in this issue, the following are included: Holland's Contribution to Cheese Making, by C. D. Kelly (p. 6); The Seed Situation for This Season, by M. T. Munn (p. 7); and Need Improved Strains of Legume Bacteria, by A. W. Hofer (p. 12).

**Forty-ninth Annual Report [of Cornell Station], 1936, C. E. LADD ET AL.** (*[New York] Cornell Sta. Rpt. 1936, pp. 63-162*).—The experimental work not previously referred to is for the most part noted elsewhere in this issue.

**Service to agriculture: Report of the West Virginia Agricultural Experiment Station for the biennium ending June 30, 1936, F. D. FROMME** (*West Virginia Sta. Bul. 278 (1936), pp. 40, figs. 4*).—The experimental work not previously referred to is for the most part noted elsewhere in this issue.

## NOTES

---

**Kansas College and Station.**—The legislature has appropriated \$2,511,000 for the support of the institution during the biennium beginning July 1, 1937. This includes as special items \$450,000 to replace the physical science building burned in 1934, \$106,700 for the four substations, \$42,000 for outlying experiment fields, \$30,000 for laboratory equipment, \$30,000 for research on diseases of livestock, and \$160,000 for extension. The physical science building will be a three-story limestone structure 300 ft. long with 80-ft. wings, and it is hoped to have it ready for occupancy in the fall of 1938.

Thomas E. Will, professor of political economy from 1894 to 1897 and president from 1897 to 1899, died in Belle Glade, Fla., on March 5 at the age of 75 years.

**Nevada Station.**—In cooperation with the U. S. D. A. Forest Service and the Division of Irrigation of the Bureau of Agricultural Engineering, the station is inaugurating a study of spring precipitation in the Lamolle Basin of the larger Humboldt River Basin. The purpose of the project is to determine the relative rainfall at a higher elevation in terms of precipitation on the basin floor, in order to determine the weight that should be given the spring precipitation in forecasting the total run-off.

A shelter cabin has been erected midway between Jarbidge and Marys River Basin for the better protection of snow surveyors. As funds become available, similar cabins will be erected in the various basins of the State.

**Cornell University.**—A State appropriation of \$30,000 has been provided for the construction of two greenhouses, each 100 by 35 ft., to be used for potato research by the departments of plant pathology and plant breeding. The houses will be partitioned into several sections, all beds will be tiled for steam sterilization, and blower fans will be used for forced air ventilation. Several small gas-proof sections will be constructed for studying the virus diseases of potatoes.

In further development of the program previously noted (E. S. R., 68, p. 876), action has been taken by the trustees of Cornell and Syracuse Universities whereby all instructions in professional forestry, both graduate and undergraduate, offered under State auspices will be concentrated after July 1 in the New York State College of Forestry at Syracuse. All professional instruction in wildlife conservation and management will be offered in the New York State College of Agriculture at Ithaca. The degree of master of forestry will no longer be given at Cornell, and its department of forestry will limit its instruction to nonprofessional courses designed to round out, as to forestry, the program of students of agriculture or of wildlife conservation and management. The extension work, however, will be continued, as well as the development of research forest properties and certain phases of other research in forestry, such as forest soils and forest pathology. C. H. Guise, professor of forest management, has been transferred to the office of resident instruction of the College of Agriculture, where he has served since February 15 as professor of personnel administration.

Provost A. R. Mann has resigned to become vice president of the General Education Board, effective July 1.

**New York State Station.**—Drs. G. J. Hucker and Carl S. Pederson, chiefs in research in bacteriology, have been granted leaves of absence for 6 months. Dr. Hucker will spend 4 months in New Zealand conferring with bacteriologists, dairy specialists, and veterinarians on the detection and control of mastitis and septic sore throat, dividing his time between the University of Hamilton, the Veterinary Laboratory at Wallaceville, and the Dairy Research Institute at Palmerton North. Dr. Pederson will study sugar spoilage in Cuba.

Majorie Rogers Crawford resigned as librarian March 15 to engage in commercial library work and has been succeeded by Rachel Evans Hening. Dr. Frederick W. Hayward has been appointed assistant in research (chemistry).

**Pennsylvania College and Station.**—Winfred W. Brame, associated with the station and the Institute of Animal Nutrition since 1903 and at the time of his retirement in 1936 associate professor of animal nutrition, died March 24 at the age of 63 years. A native of Massachusetts, he was graduated from Worcester Polytechnic Institute in 1897 and received the M. S. degree from the college in 1908. He has been succeeded by Dr. Seth R. Johnson.

**Utah College and Station.**—Dr. W. E. Carroll, professor and chief of swine husbandry in the Illinois University and Station, has been appointed dean of the School of Agriculture and animal husbandman in the station, effective July 1.

**Virginia Station.**—Frances Hicks Bass, assistant in household engineering, resigned March 31. R. E. O'Brien, Jr., has been appointed assistant agronomist, effective March 1.

**Washington College and Station.**—A substantial increase in appropriations for the next 2 years will permit of some much needed additions to the teaching and research staffs and some increases in maintenance allotments. A special appropriation of \$62,500 was made for the establishment of a tree fruit substation in the Wenatchee fruit-growing region.

Through the new Department of Social Security of the State and the State Planning Council, a fund of \$37,000 has been allotted for soil surveys for the biennium ending March 31, 1939. The work will be a part of the project on soil survey and land classification conducted by the station in cooperation with the State Planning Council.

Robert D. Eichmann has been appointed assistant entomologist in the station beginning April 10. Walter J. Clore, research assistant in horticulture, has been appointed assistant horticulturist of the main station and horticulturist of the Irrigation Substation, and will work primarily on problems of vegetable crops.

**American Meteorological Society.**—At a meeting held at the U. S. D. A. Weather Bureau, Washington, D. C., April 28-29, 1937, the principal themes were long-time trends of weather, droughts, and long-range forecasting pertinent thereto; and physical bases for the development and movement of pressure systems and the air masses of which they are constituted, with suggestions of lines along which further research is especially needed. Sound films prepared by the Department of Agriculture on the subjects of Fire Weather and Flood Weather were presented, and there was an exhibit of radiometeorographs. A joint session was held with the American Geophysical Union.

# INDEX OF SUBJECTS

**NOTE**—The abbreviations "Ala.", "Conn.[New Haven]", "Mass.", etc., after entries refer to the publications of the respective State experiment stations; "Hawaii" and "P.R." to those of the experiment stations in Hawaii and Puerto Rico; "Can." to those of the experiment stations in Canada; and "U.S.D.A." to those of this Department.

Abortin, use. U.S.D.A. 688.

Abortion—*see also* *Brucella abortus*.

agglutination test in cattle, low titer reactions to, Mo. 689.

agglutination test, 1:50 and subsequent test behavior, 536.

control and eradication, Mich. 689.

control in breeding herds, Tenn. 102.

detection and control, U.S.D.A. 688.

diagnosis, agglutination value, 10, importance in, 248.

immunization studies, 102; Mich. 689, 849.

in mares, experimental studies, 244.

in swine, transmission to cattle, Mo. 689.

in swine, vaccination against, Calif. 848, low agglutination titers in, significance, 248.

studies, 248; Ariz. 97; Colo. 533; Tex. 533.

testing, Mo. 689.

transmissibility among dairy cattle in a Utah dairy village, Utah 248.

whey tests for diagnosis, Calif. 848.

*Acallestes camelus*, new from South America, 512.

*Acanthomyops niger*, poison bait for, 518.

*Acanthoscelides obtectus*, *see* Bean weevil.

Acetylmethylcarbinol in bread, relation to bread flavor, 878.

*Achorion muris*, notes, 99.

*Achorutes armatus* in mushroom beds, 67.

*Achroia grisella* in Oregon and California, 501.

*Achromobacter* sp., cause of musty flavor in butter, 532.

Acid phosphate, *see* Superphosphate.

Acids—

amino, *see* Amino acids.

fatty, *see* Fatty acids.

organic, metabolism in plants, 456.

*Acrobasis caryae*, *see* Pecan nut casebearer.

*Acrocoella jehovae*, attendance on citrus mealybug of Palestine, 215.

*Acrospermum compressum*, development of ascocarp, 18.

*Actinomyces* spp. from scabby potatoes, comparative study, [N.Y.]Cornell 804.

Addison's disease and vitamin C deficiency, relation, 888.

Adenylic acid, role in vitamin B<sub>1</sub> deficiency, 885.

Adobe construction, 550.

Adolescence, research in, 720.

*Aenoplex carpopapsae*, effect on codling moth, Mo. 655.

*Aeolothrips bicolor*, notes, S.C. 217.

*Aerobacter aerogenes*, indol tolerance, 691.

Aerobic and anaerobic dissimilations, macrorespirometer for study, 18.

Agar plate technic, standard, proposed changes in, 312, 527.

*Agave*, genetic studies, 609.

Agglutination—

specific bacterial, important factor in mechanism, 97.

testing, Mich. 689.

tests, tube v. plate tests on low reacting serums, Mo. 689.

Agricultural—

adjustment and farm tenure, 407.

balance, data, U.S.D.A. 551.

census of Canadian Provinces, 407.

census, world, data on Union of South Africa, Australia, Finland, Argentina, and Peru, 557.

college freshmen, bases for predicting scholastic success, 715.

colleges—*see also* Iowa, Kansas, Massachusetts, *etc.*

nutrition courses in, 715.

credit research in FCA, 407.

credit situation in Maryland, handbook, Md. 122.

credit, sources and costs, [N.Y.]Cornell 863.

credit system, 551.

credit, treatise, 260.

depression, graphic summary, Tenn., 863.

development and grasshoppers in North Dakota, 862.

Economics, Canadian Society, proceedings, 407.

economics—*see also* Farm economic.

work at University College of Wales, 863.

## Agricultural—Continued.

education, graduates in, preemployment records and activities, Pa. 288.

education in world, 417.

engineering, *see* Engineering.

extension, *see* Extension.

industry in Illinois, future population in, 265.

journals, new, 143, 576, 736.

labor—*see also* Labor.

income of landlords and tenants, Ark. 705.

of California, contemporary background, 875.

of California, historical background, 266.

wages, 707.

legislation, international yearbook, 264

machinery—*see also* Combines, Thresher, *etc.*

for harvesting buffalo grass seed, 114.

for sugar beets, new developments in, 860.

improvement, 404.

testing, measuring apparatus for, 404.

museums, references on, U.S.D.A. 418

organization in New Zealand, 413

outlook for Illinois, Ill 864

policy, Canadian, 407.

prices, textbook, 711.

production, adjustments in to conserve fertility and prevent erosion, Ky. 117

production control, adjustments in cropping systems due to, Mo. 705.

products—

cost of production, N.C. 119.

demand and prices, outlook, Okla 551.

drying, 702.

marketing, *see* Marketing.

of Ohio farms, estimated gross cash income from, 260

of Oklahoma, purchasing power, Okla. 408.

prices in New York State, 1941 to 1935, [N.Y.]Cornell 263.

production-consumption balance, Mich. 709.

readjustments in northern New England from 1790 to 1930, 872.

relief, *see* Relief.

research, application of statistical methods to, 575.

situation, Okla. 408.

situation, world, 410.

situation, world, treatise, 705.

statistics, U.S.D.A. 124.

statistics, international yearbook, 415, 712.

statistics of Ohio, Ohio 871.

tenancy, *see* Farm tenancy, Farm tenure, and Land tenure.

workers on relief in California, 865.

## Agriculture—

and industry, production control in, 407.

application of physics to, 178.

Department of, *see* United States Department of Agriculture.

electricity in, *see* Electricity.

in Maine in 1935, Me. 259.

in Washington, trends and desirable adjustments, Wash. 410.

in West Virginia, trends, W.Va. 118.

income in, 706.

Agromyzidae, new Central American, descriptions, 366.

Agronomy, statistical methods and application to, 468.

*Agropyron* and *Triticum*, hybridization, 610

*Agrostis nebulosa*, chromosome behavior in, 173.

*Agrilus*, *see* Cutworms.

Air—

cleaner performance, Calif. 857

conditioning and engineering, treatise, 406.

coolers, home-made, description, 117.

effect on unweighted and tin weighted silk, 891.

humidities, effects of altering on vapor pressure gradients, 460.

mass analysis, introduction to study, 5.

*Alabama argillacea*, *see* Cotton leaf worm.

Albumin, blood, spreader used with oil sprays, 359.

Albumin, egg—

acetone dried, lysozyme from, 581

as sole source of protein and vitamin B<sub>2</sub> for rats, toxic effects, 419.

foaming, 560.

height of firm portion as measure of condition, 379.

isoelectric point, effect of method of preparation and of cations, 741.

ovoglobulin in, change in concentration during egg formation, 380

seasonal variation in performance, 716

thickness, factors affecting, U.S.D.A. 612.

*Alcaligenes viscosus*, studies, 93.

Alcohol—

and gasoline blends for high compression eight-cylinder automobile engine, 859.

and gasoline blends, tests, 547.

as fuel for automotive engines, 859.

Alcohols, fatty, rhodanates of as insecticides, 215.

*Aleurocanthus woglumi*, *see* Blackfly, citrus.

*Aleuroglyphus*—

*agilis* and *Cheyletus eruditus*, interaction between, 213.

*ovatus*, heat and cold resistance, relation to temperature of development, 358.

## Alfalfa—

- aphid, notes, U.S.D.A. 654.
- bacterial wilt and winter-killing, control, Colo. 486.
- breeding, Calif. 780; U.S.D.A. 617.
- bromegrass mixture, good pasture from, Mich. 618.
- cold resistance in, relation to reserves, Iowa 619.
- cutting, late summer and early fall, effect, 782.
- cutting tests, Hawaii 780.
- cuttings, stimulation of root formation, 470.
- dwarf, transmissible by grafting, 344.
- failure, cause, Ky. 46.
- fatigue of soils cropped to, role of bacteriophage, 599.
- freshly cut, v. alfalfa leaf and blossom meal for poultry, Hawaii 835.
- green color and carotene in, factors affecting, U.S.D.A. 528.
- grown in South Africa, vitamin C in, 429.
- hay as sole ration for dairy cattle, Nev 227.
- hay, chopped, storage in ventilated containers, 703.
- hay, chopping and storing, Ind 549.
- hay, chopping at time of storage, 842.
- hay, color, effect of variations in sun exposure, Ariz. 29.
- hay, composition, digestibility, and milk-producing value, Va. 383.
- hay, feeding value, Mich 678.
- hay from phosphorus-treated ground, feeding value, Ariz. 89.
- hay improvement and avoidance of winter injury, Mich. 618.
- hay in storage, color and pigments, 527.
- hay, long v. chopped, for pregnant ewes, [N.Y.]Cornell 835.
- hay, third cutting, vitamin A activity, effect of curing, 680.
- hay, vitamin A in, effect of storage, 836.
- hay, vitamins in, Colo. 518.
- inheritance studies, Ariz. 29.
- inoculation studies, Colo 468.
- Iadak, tests of merit, Mont. 618.
- leaves, moisture content when shattering occurs, 703.
- longevity and growth, relation to frequency of cutting, [N.Y.]Cornell 781.
- looper, control with pyrethrum dusts, Colo. 501.
- looper outbreak, 656.
- meal as protein supplement for pregnant sows, Mich. 668.
- meal, effect on development of body organs of cockerels, 229.
- meal, feeding value for pigs, 229.
- molasses silage v. alfalfa hay, feeding value, Mich. 679.
- nodules, abnormal structure, effect of nitrate supply to host, 770.

## Alfalfa—Continued.

- on alkaline calcareous soils, fertilization, Ariz. 825.
  - Peronospora trifoliorum*, on, in New Mexico, U.S.D.A. 685.
  - pollination in, mechanism, 782.
  - production-consumption balance, Mich. 709.
  - response to degrees of liming, W.Va. 762.
  - root development, effect of reaction of soil strata, 162.
  - root hairs, infection by nodule bacteria, effect of sodium nitrate, 14.
  - seed, lygaeid plant bugs and pentatomid bugs on, U.S.D.A. 654.
  - silage, see Silage.
  - snout beetle, control, [N.Y.]Cornell 820.
  - snout beetle in New York, status, 368.
  - snout beetle, parthenogenetic, early embryological development, 78.
  - soils, fatigue of, causes and remedies, 200, 201.
  - stands, duration, effects of various treatments, Ark. 617.
  - time for seeding, Vt. 178.
  - timothy mixtures, fertilizer experiments, N.H. 469.
  - use of ammonium phosphate for, Ariz. 6.
  - variety tests, Ky. 29; Tex. 468.
  - weevil, notes, U.S.D.A. 654.
  - weevil, status and control, 369.
  - yield and composition, effect of fertilizers and soil types, 29.
- Alfalaria, galls on, Ariz. 46.
- Algae, green, auxins from, effect on *Phytophthora cactorum*, 17.
- Algae, marine, mineral composition, Hawaii 877.
- Alkali—
- disease, causative agent, U.S.D.A. 375.
  - disease or selenium poisoning, 246.
  - soils, black, reclamation with various kinds of sulfur, Calif. 309.
  - soils, reclamation by electrodialysis, 450.
  - soils, white, reclamation in Imperial Valley, Calif. 308.
- Alkaline soils, acidulated fertilizers for, 760.
- Allantoin occurring in maggot secretions, stimulation of healing by, 690.
- Allergy, clinical, in humans and experimental anaphylaxis in animals, basic identity, 571.
- Almond—
- Coryneum* blight and blossom blight, Calif. 804.
  - tree blight, 817.
- Almonds—
- breeding, U.S.D.A. 625.
  - effect of ammonium sulfate, 800.
- Alternaria—
- leaf blight of flax, Ariz. 46.
  - solani* on tomatoes, temperature studies, U.S.D.A. 59.
  - sp., cause of blackening of wheat, 490.
  - sp., cause of tomato black rot, 208.

**Alternaria**—Continued.

- tenuis*, notes, Conn. [New Haven] 206.
- tenuis* on cotton in Peru, 642.
- tomato* on tomatoes, temperature studies, U.S.D.A. 59.

**Aluotia niveodactyla**, pest of sweetpotatoes in Kwangtung, 660.

**Aluminosilicates**, colloidal, swelling, Mo. 589.

**Aluminum**, beneficial effect on citrus, 603.

**Amaranth**, Chinese varieties, vitamin C in, 279.

**Amauronematus lineatus** in Illinois, 226.

**Ameba** studies, Mich. 689.

**Ameba pallorana** attacking pine, 501.

**American**—

- Meteorological Society, meeting, 896.
- Public Health Association, standard agar plate technic, proposed change in, 527.
- Society of Agronomy, meeting, 288.

**Amidostomum anseris** of geese in western Washington, 108.

**Amino acids**—

- and peptides, studies, 740.
- excretion from root nodules of legumes, 315.
- in crystalline pepsin, determination, 584.
- in wheat, U.S.D.A. 579.

**Ammonia**—

- nitrogen in eggs, microdetermination, Mich. 154.
- source of loss in Kjeldahl distillations, 748.

**Ammonium**—

- salts, photonitrification, 596.
- sulfate, effect on *Heterodera schachtii* infected soil, 58.
- sulfate fertilizer, behavior, 800.

**Amoebotaenia**—

- cuneata* in partridges, 252.
- sphenoides*, notes, P.R. 856.

**Amphicercoidus mawsoni** n.sp., description, 863.

**Amphorophora rubi**, notes, N.Y. State 351.

**Amylase**,  $\beta$ -malt, reversible inhibition by ascorbic acid and related compounds, 428.

**Anabasine**, toxic action on bean aphid, 360.

**Anabrus simplex**, see Cricket, Mormon.

**Anaerobes**, sporulating, cultivation and identification, semisolid media for, 770.

**Analysis**, biometric, outline, 894.

**Anaphothrips concinnus**, notes, 69.

**Anaplasmosis**—

- bovine, transmission by ticks, 249.
- diagnosis, applicability of complement fixation in, U.S.D.A. 649.
- effect on blood cells of host, 535.
- immunization, 534.
- in sheep and goats, Tex. 533.
- in sheep in France, 250.
- mechanical transmission by unclean instruments, 97.

**Anarsia lineatella**, see Peach twig borer.

**Anarsia jatrophae** in Texas, 71.

**Anastrepha**—

- fraterculus*, see Fruitfly, West Indian.
- ludens*, see Fruitfly, Mexican.
- serpentina*, control, U.S.D.A. 654.

**Anatis**, anatomical and systematic study of genus, 665.

**Andrews Bald**, origin, 12.

**Androsterone**—

- effect on accessory reproductive organs of rodents, 780.
- response of comb growth in capons to, 779.
- site of injection, relation to comb response in fowls, 613.
- synthetic, effects on accessory reproductive organs of male ground squirrel, 466.

**Anemia**—

- caused by deaminized casein, 889; Mo. 668.
- diseases causing, relation to gaseous oedema, 536.
- equine infectious—
  - in New England, 540.
  - in northern Sweden, 395.
  - mercuric chloride test for, 540.
  - outbreak, blood changes in, 540.
  - studies, U.S.D.A. 688.
- hypochromic, in pregnancy, prevention, 188.
- in pregnancy, 729.
- nutritional, blood and blood-forming organs during recovery from, Hawaii 877.
- nutritional, cured by evaporated milk supplemented with iron, 130.
- nutritional, of infants, treatment, 138.
- pernicious—
  - etiology and treatment, 730.
  - extrinsic factor for, 425.
  - lactoflavin and extrinsic factor in, nonidentity, 839.

**Anemias of childhood**, 188.

**Anesthesia**, effect on urinary excretion and tissue fixation of ascorbic acid, 428.

**Angitia** spp., for control of diamondback moth in New Zealand, 219.

**Angoumois grain moth** eggs as food for cucujid beetle in *Tricogramma* laboratory, Colo. 224.

**Anguillulina dipsaci**—

- in bulbous iris, detection, U.S.D.A. 339.
- natural transfer from clover to strawberry plant, 210.
- on potatoes, 810.
- on rhubarb in Yorkshire, 644.
- on tomato stems and leafstalks, 354.

**Angular leaf spot**, wild hosts, insect transmission, Ky. 46.

**Animal**—

- chromosomes, see Chromosomes.
- diseases—see also specific diseases.
  - and parasites in California, 689.
  - and parasites in Kenya, 244.
  - due to anaerobes, 243.
  - in Southern Rhodesia, 689.

**Animal—Continued.****diseases—continued.**

laboratory diagnosis, epizootological data from, 244.

notes, 639.

nutritional, and mineral deficiencies, Colo. 532.

parasitic, cutaneous reactions and diagnosis, 848.

**Apparatus—**

differential refractometer, description, 747.

fat stability, Swift, for approximating end of induction period, improvement, 749.

for determination of momentary amount of assimilation, 490.

## Apparatus—Continued.

- for determining carbon dioxide production of flour sample, 437.
- for measurement of  $\text{CO}_2$  evolved during decomposition of soil organic matter, 450.
- for measuring rate of streaming of atmospheric gases into interior of living sections of woody stems, 765.
- for rapid counting of large numbers of small insects, 65.
- for sugar titrations, 749.
- melting point, electrically heated, 746.
- multiple-unit distilling for determination of fluorine, 149.
- new, for carbonic acid estimations in soils, 151.
- ring shearing, for determination of shearing resistance and plastic flow, 401.
- self-sealing vessels for storage of solutions used in Van Slyke gasometric methods, 747.
- sensitive check valve, 747.

## Apple—

- aphid, rosy, control and status, 501, 823.
- aphid, woolly, resistance and immunity of apples to, 829.
- bitter rot control, 60, 350.
- black pox due to black root rot fungus, W.Va. 804.
- blossoms, fire blight bacteria penetration, mode, Ark. 195.
- blossoms, spraying and dusting, effect on set of fruit, [N.Y.]Cornell 791.
- blotchy cork, relation to diminution of calcium in fruit, 350.
- clons, root systems, 629.
- cork and rosette disease, [N.Y.]Cornell 804.
- curculio, larger, in Wisconsin, 78.
- curculio, notes, N.Y.State 656.
- die-back and rosette, Calif. 803.
- disease, new, 815.
- diseases in Pennsylvania, U.S.D.A. 635.
- diseases, nonparasitic, in storage, 495.
- fire blight—
  - in young trees, relation to orchard practices, [N.Y.]Cornell 804.
  - of Stayman variety, relation to nitrogen-carbohydrate nutrition, 350.
  - organism overwintering in trees suffering from severe winter injury, [N.Y.]Cornell 804.
- flowers, selfed and crossed, pollen tube growth in, Ark. 625.
- foliage photosynthetic efficiency, [N.Y.]Cornell 791.
- fruit buds, winter injury to, nature, W.Va. 790.
- insects and diseases, cost of control, 826.
- insects, control, factors in, 823.
- juice, studies, N.Y.State 579.
- leaf scorch, control, [N.Y.]Cornell 804.
- leaf structure, relation to position on shoot and type of growth, 794.

## Apple—Continued.

- leafhopper, white, studies, 65; Conn. [New Haven] 733; N.Y.State 656.
- leaves, carbon dioxide assimilation, effect of flotation sulfur spray on, 794.
- leaves, photosynthetic activity, methods of measuring, 794.
- losses from diseases in 1935, U.S.D.A. 339.
- maggot, notes, 65; N.Y.State 656.
- measles, Mo. 636.
- orchards, cover crops for, Ky. 38.
- orchards, practical sanitation, 220.
- orchards, soil management, Tenn. 38.
- packing sheds, mothproofing, Mo. 655.
- pest control with tar oil sprays, 826.
- pests, dormant oil sprays for, N.Y. State 826.
- pollen tubes, growth, effect of pistil and ovary extracts, Ark. 625.
- pomace, dried, imitation jelly from, 299.
- pomace, pectic extractions, enzymatic hydrolysis of starch in, Del. 581.
- pomace, treatment for pectic extraction, 298.
- powder and other fruit products U.S.D.A. 579.
- pulp pectin, effect of sulfurous acid, 298.
- roots, depth of penetration, W.Va. 790.
- rootstocks, moisture content of stems, 793.
- rootstocks, percentage of rooted shoots to be expected from mother plantation 792.
- rootstocks, testing, W.Va. 790.
- rust, control in Hudson Valley, N.Y.State 636.
- rust control, spray materials for, 495.
- rust, relative susceptibility of orchard apples to, index, 814.
- scab, control, 495; Mich. 635; [N.Y.]Cornell 804; N.Y.State 636.
- scab, prevention, dilute and modified sprays for, 495.
- scab resistance, variety tests, N.Y.State 815.
- scab spraying tests, 636.
- target canker, Mo. 636.
- terminals, seasonal changes in soluble nitrogen and phosphate phosphorus content, Ky. 38.
- thinnings as source of pectin, N.Y.State 745.
- tree borer, flat-headed, on pecan, Ga. 358.
- trees, Baldwin, winter injury, relation to overwintering of fire blight organism, 350.
- trees, closely planted one-year-old, phosphate response with, 334.
- trees, double working in nursery, Mich. 188.
- trees, effect of potassium fertilizer, 41.
- trees, growth on own and seedling roots, variation in, Del. 625.
- trees, growth, relation to soil properties, Mich. 187.

## Apple—Continued.

- trees, mulching, effect, 795.
- trees planted in cylinders, distribution and condition of potassium, 456.
- trees, rain distribution under, 795.
- trees, root growth, [N.Y.]Cornell 791.
- trees, trunkless, 794.
- trees, young, methods of training, W.Va. 790.
- trees, young, top working, N.Y.State 629.
- trees, young, training, crotch angles as affected by method, 793
- woolly knot organism, Siegler's, microscopic studies, 637.

## Apples—

- breeding, N.Y.State 629
- breeding, example of parental prepotency in two progenies of Delicious, 772.
- breeding, fruit color data, 335
- bruising and storage quality, effect of washing for spray-residue removal 40; [N.Y.]Cornell 791.
- canning, costs, Wash. 717.
- chromosomal structure in, N.Y.State 629
- Cortland and McIntosh, keeping quality, effect of time of harvest, [N.Y.]Cornell 791.
- culture experiments, Ky. 38.
- fertilizer experiments, 795.
- fertilizers for, comparison, Mo. 625.
- Gravenstein, situation, Calif. 863.
- in storage, Freon as refrigerant for, 117.
- Jonathan, acetaldehyde and alcohol content, 16.
- Jonathan, arsenical injury to fruit and foliage, 215.
- Jonathan, total soluble solids and catalase in different parts, 16
- keeping quality, effect of careless handling, [N.Y.]Cornell 791
- Lane Prince Albert, root systems on two selected rootstocks, 793.
- losses in moisture, relation to washing treatments, Wash. 188.
- Malling clonal stocks in relation to McIntosh and Wealthy, 792
- McIntosh, fruit bud differentiation, 335
- McIntosh, fruit characters, effect of food manufactured by Northern Spy leaves, 794; [N.Y.]Cornell 791.
- McIntosh, fruit set, best distribution for pollinizer trees in orchard, [N.Y.]Cornell 791.
- measuring developmental and ripening changes in, electrical maturity tester for, 478.
- metaxenia in, 795
- Nelson, internal cork and moisture content of soil, 351.
- nitrogen fertilizers, fall and spring applications, 334.
- pollen production by varieties, 477.
- pollination, effect of length of day, Mo. 625.
- premature dropping, relation to curculio injury, Del. 625.

## Apples—Continued.

- production and marketing, economics of, N.Mex. 262.
- pruning, Ark. 625.
- shipments from Shenandoah-Cumberland region to overseas markets, U.S.D.A. 188.
- size, relation to number of seeds and weight of spur leaves, 477.
- Stayman Winesap, cracking, W.Va. 790.
- Stayman Winesap, sterility in, cause, Ark. 625.
- stored, effect of ethylene, ethylene chlorohydrin, and ultraviolet irradiation, W.Va. 790.
- top and root growth made by on seedling and scion roots, 793.
- varieties, Colo. 476.
- varieties and plantings, Del. 707.
- varieties in Sweden, 727.
- varieties, new, characteristics and status, N.Y.State 795.
- varieties, number of pollen grains produced by, W.Va. 790.
- varieties, prices and yields, [N.Y.]Cornell 863.
- vascular anatomy, N.Y.State 629.
- vitamin C content, factors affecting, 566.
- washing machines, heating systems for, Ill. 116.
- wax treatments, effect, 796.
- Winesap, red color in skins, chemical nature of pigment, W.Va. 790.
- yield and cost of production, Mich. 708.

## Apricot—

- branches, dying back due to *Sclerotinia sclerotiorum*, 646.
- trees, closely planted one-year-old, phosphate response with, 334.

## Apricots—

- Cytospora* canker of, Ariz. 46.
- green rotting due to *Sclerotinia sclerotiorum*, 646
- growth study, 629.
- thinning, 336.

## Aresket, Areskap, and Aresklene, new wetting agents, 67.

*Argyrolacla* n.sp., notes, 662.*Argyroploce leucotreta* on citrus in western Transvaal, control, 215.*Argyrotaenia citrana*, biology, 660.*Aristotelia eldorado*, notes, 662.

## Arizona Station, notes, 142, 743.

## Arizona Station, report, 141.

## Arizona University, notes, 142, 734.

## Arkansas Station, report, 732.

*Armillaria mellea* root rot of rhubarb and of privet, Tex. 488.*Armillaria mellea*, wild and cultivated hosts, and control, 195.

## Armyworm, fall—

- notes, N.Y.State 656; U.S.D.A. 654.
- on corn, Ga. 358.
- role in cotton wilt transmission, 809.

- Armyworms**—  
of Pennsylvania, manual, Pa. 831.  
outbreak in Queensland, 662.
- Arsenic**—  
in grasshopper bait, effect on chickens, 359.  
in tissues of rats and baby chicks, Ky. 81.  
injury to plants, inhibition by phosphorus, 489.  
penetration into insects, N.H. 503.  
pentoxide, effect on bait, Tex. 502.  
preparations as dust fungicides, tests, 51.  
toxicity, effect of soil texture on, Calif. 780.
- Arsenical**—  
insecticides, effect on wild game and farm animals, 246.  
spray residue, *see* Spray residue and specific fruits and vegetables.  
substitutes, 361.
- Artemisia**, aphids infesting, 659.
- Arthropods**, new intermediate hosts, Hawaii, 820.
- Artichokes**—  
culture in America, 178.  
tuberization regulated by capping stem tips with black cloth, 607.
- Ascaridia**—  
*gallii*, notes, P.R. 856.  
*lineata* in fowls, treatment, 397.
- Aschersonia** spp. on citrus, 648.
- Ascia rapae**, *see* Cabbageworm, imported.
- Asioleptus**—  
chromosome number in, 173.  
latex, electrophoresis, 178.  
testing for rubber production, U.S.D.A. 625.
- Ascochyta**—  
*cinerariae*, description, 818.  
*psii violae* in seeds of vetch, 349.  
spp., relation to fruit rot, 485.
- Ascogaster carpocapsae**—  
notes, N.Y.State 656.  
parasite of codling moth larva, Colo. 501.
- Ascomycetes**, morphology and life history, 686.
- Ascomycetes** sporulation, effect of certain fungi, 173.
- Ascorbic acid**—*see also* Vitamin C.  
antiscorbutic activity, relation to mode of administration, 280.  
concentration in organs of rat on incomplete diet, 184, 568.  
determination by means of 2,6-dichlorophenolindophenol, 155.  
determination, new form of method, 155.  
determination, review of methods, 155.  
excretion in urine, 135, 568.  
in blood, reduced, determination, 750.  
inactivation of tobacco mosaic virus by, 645.  
L, and chemically related compounds, behavior in animal body, 427, 428.
- Ascorbic acid**—Continued.  
precipitation and color reaction for, 743.  
relation to development of oxidized flavor in milk, [N.Y.]Cornell 841.  
reversible inhibition of  $\beta$ -malt-amylase by, 428.  
silver nitrate as test for, conditions of reaction, 296.  
storage by guinea pigs, 888.  
working mechanism in normal and pathological conditions, 282.
- Ash**, American species, flowering and fruiting habits, 633.
- Ash canker**, control, Ariz. 46.
- Asiatic beetle**—  
importation of natural enemies, U.S.D.A. 654.  
larvae injury to turf, prevention, U.S.D.A. 366.  
light traps for, recent developments in, 664.
- Asiatic garden beetle**—  
construction and use of light traps for, U.S.D.A. 501.  
life history and control, U.S.D.A. 665.
- Asparagine** in tobacco leaves, 580.
- Asparagus**—  
culture, Tenn. 38.  
fertilizers and manures for, [N.Y.]Cornell, 790.  
fertilizers for, Tex. 476.  
frozen pack, micro-organisms in, numbers and types, 878.  
precooling prior to long distance shipments, Calif. 790.  
rust in New Jersey, U.S.D.A. 339.
- Asparagus sprengeri**, crown gall of fasciated type, U.S.D.A. 803.
- Aspen areas**, reclamation, U.S.D.A. 632.
- Aspergillus niger**—  
acid formation by, effect of mineral elements of nutrient medium, 602.  
effect of barium salts, 13.  
method, observations on, 599.  
parasitism of *Penicillium rugulosum* on, 638.
- Aspidiotus**—  
*lataniae* on avocados, fumigation control, 659.  
*pernicius*, *see* San José scale.
- Association of**—  
American Feed Control Officials, convention, 287.  
Land-Grant Colleges and Universities, convention, editorial, 1.  
Land-Grant Colleges and Universities, officers elected, 3, 144.  
Land Grant Colleges and Universities, proceedings, 270.  
Land-Grant Colleges and Universities, research at 1936 convention, editorial, 145.  
Official Agricultural Chemists, meeting, 287.

## Association of—Continued.

Official Agricultural Chemists, official and tentative methods of analysis, 747.

Official Seed Analysts of North America, proceedings, 787.

Aster rust, control, [N.Y.]Cornell 804.

Asters, China, photoperiodism, [N.Y.]Cornell 800.

*Astragalus hylophilus*, selective habitat, 538.

*Ataia crypta* role in cotton wilt transmission, 809.

Atlas, socio-economic, of Oklahoma, Okla. 864.

Baby beef, *see* Cattle, baby beef.

*Bacillus*—

A, B, and C in rice seed in Japan, 204.

*abortus*, *see* Abortion and *Brucella abortus*.

*amylovorus*—

infection, relation to nitrogen-carbohydrate nutrition, 850.

longevity, effect of dry air, 849.

notes, [N.Y.]Cornell 648.

overwintering in cankers on winter-injured trees, 350.

*Bacillus*—Continued.

*betanigrifloans* n.sp., notes, 441.

*botulinus*, *see* *Clostridium botulinum*.

*carotovorus*, notes, 847.

*coli communis*, effect on vitamin C, 184.

*concomitans* n.sp., description, 172.

*mycoides*, adsorption by soils, [N.Y.]Cornell 758.

*paratyphosus*, effect on vitamin C, 184.

*radicicola*—*see also* Legumes, inoculation, and Nodule bacteria.

bacteriophage specific for, relation to loss of vigor of legumes, 599.

## Bacon—

pigs, fattening, dried beet pulp, 229.

pigs, net energy requirement, 87.

sliced cured, storing in oils, Tex. 517.

soft, causes, 674.

work of Food Investigation Board of Great Britain, 877.

## Bacteria—

adhesion to fabrics used for children's clothing, 283.

adsorption by soils, [N.Y.]Cornell 757.

anaerobic, *see* Anaerobes.

causing lactic fermentations, N.Y. State 579.

coliform, types in bovine feces, 385.

in milk and soil, *see* Milk and Soil.

in prepared foods, N.Y.State 271.

in rice seed, 204.

intestinal, effect on vitamin C, 134.

oxygen supply and requirements, [N.Y.]Cornell 764.

## Bacterial—

flora of foremilk and of rennet extract, 242.

flora of stomach and large intestine, effect of fruit ingestion before meals, 127.

spores, viability after exposure to temperatures near absolute zero, 17.

Bacteriologic culture media, *see* Culture media.

## Bacteriophage—

and fatigue of soils in alfalfa, 200, 201.  
phenomena in cultures of lactic streptococci, 386.

role in epidemics of mouse typhoid, 245.  
role in fatigue of soils cropped to alfalfa, 599.

Bacteriosis, studies, 340.

*Bacterium*—

*aerogenes*, effect on cream quality, 93.

*aerogenes* in bovine feces, 385.

*aertrycke* in herd of mice, experimental epidemiology, 244.

associated with fasciation of plants and leafy gall, 340.

*citri*, *see* Citrus canker.

*cloacae* in bovine feces, 385.

*coli*, effect on cream quality, 93.

*coli* in bovine feces, 385.

*dissolvens*, notes, U.S.D.A. 339.

**Bacterium**—Continued.

*enteritidis* in herd of mice, experimental epidemiology, 244.

*lachrymans*, notes, 492.

*medicaginis phascolicola*, notes, 491.

*paludis* from sheep in North Wales, 393.

*pruni* on cherry, Mo. 636.

*pullorum*, see *Salmonella pullorum* and Pullorum disease.

*solanacearum*, notes, Fla. 346.

*stewartii*, selection for virulence in, 20.

*translucens undulosum*, cause of black ening of wheat, 490.

*tumefaciens*—

chemical composition, 195.

hormone extracted from, 340.

in culture media, 637.

tumors caused by, culturing embryos and plants for study, 806.

*welchii*, see *Clostridium welchii*.

*Bactrocera cucurbitae*, see Melonfly.

**Badgers**—

distribution around Denbigh, food and habits, 210.

raising in captivity, U.S.D.A. 356.

**Bagasse**—

molasses, and pineapple bran mixtures, feeding value, Hawaii 841.

molasses, pineapple bran, and soybean oil meal mixture, feeding value, Hawaii 835.

Bakery products, staling, U.S.D.A. 579.

Baking tests, experimental and commercial, correlation, 877.

*Balaninus uniformis*, notes, 656.

Banana beetle, notes, 824.

Bang, B. selected works, 847.

Banks, commercial, agricultural loans of, U.S.D.A. 121.

Bantams, raising, 211.

Barberry eradication, U.S.D.A. 635.

Barium salts, effect on *Ispergillus niger*, 13

**Barley**—

acres, yields, and total production, U.S.D.A. 712.

and hay ration, plane and nutrition and digestibility, 671.

breeding, Calif. 780; Mo. 618; [N.Y.] Cornell 780; Tenn. 29; Tex. 468; U.S.D.A. 617.

breeding, problems and results, U.S.D.A. 28.

covered smut, toxicity of precipitated sulfur for, 640.

cross, appearance of awn characters in, 174.

culture experiments, W.Va. 781.

deficiencies for swine feeding, Calif. 834.

disease reaction and yield, effect of environment, 808.

fall growth, analyses, Ky. 29.

leaves, nitrogen metabolism in relation to nutrient deficiency and age, 170.

loose smut infection, factors affecting, 842.

**Barley**—Continued.

losses from diseases in 1935, U.S.D.A. 339.

molasses v. pineapple bran-molasses ration for fattening pigs, Hawaii 835.

pasture, Mo. 668.

pasture, winter, for swine, Mo. 668.

production-consumption balance, Mich. 709.

production in Colorado, Colo. 470.

rust, studies, 640.

seed, germination, effect of seed borne pathogens and of seed disinfectants, 342.

seed, *Helminthosporium* spp. on, N.Y. State 636.

seed, internal disinfection, 52.

varieties, clipping tests, Ariz. 29.

variety tests, Ariz. 29; Ark. 617; Mich. 619; Mo. 618; Mont. 618; Tex. 468.

vernalization experiments, 27.

yellow rust, biological races, seedling susceptibility, 49.

Barns, masonry, design and construction, Iowa 704.

Basic slag, see Phosphatic slag.

Bass, feeding experiments, [N.Y.] Cornell 821.

Basswood *Nectria* canker, [N.Y.] Cornell 804.

*Batocera* in Malaya, new egg parasites, 80.

**Bats** -

hematophagous, resistance to rabies virus, 535.

vampire, transmitting agent of paralytic rabies, 100.

**Bean**—

aphid, toxic action of nicotine, nornicotine, and anabasine, 360.

aphid, transmission of bean mosaic virus by, 659.

beetle, Mexican control, 823; Conn. [New Haven] 733; N.Y. State 656; Tenn. 65.

beetle, Mexican, control in association with powdery mildew disease on snap beans, 358.

beetle, Mexican, notes, U.S.D.A. 654.

diseases, virus, in Kwangtung Province, 195.

fruit and leaves, enzyme system, effect of shortening the day, 167.

halo blight, control, 54.

halo blight, varietal resistance, 491.

leafhopper, control, 658.

losses from diseases in 1935, U.S.D.A. 339.

mosaic, transmission by aphids, 344, 659.

pod borer, Ilma, notes, U.S.D.A. 654.

powdery mildew, inheritance of resistance to, Calif. 641.

root rots, Ga. 339.

rust hyphae and haustoria in unsectioned leaf tissue, demonstrating, 688.

rust in eastern Virginia, U.S.D.A. 635.

rust in New Jersey, U.S.D.A. 339.

seedlings, growth-substance inactivator from, 602.

**Bean—Continued.**

- thrips, control, Calif. 824.
- weevil, rate of growth and size, relation to temperature and humidity, 368.
- Beans—*see also* Soybeans, Velvetbeans, *etc.*
- breeding, Calif. 780; U.S.D.A. 625.
- canning, diseases in New York, U.S.D.A. 339.

Brambles, wild, as carriers of diseases and insect pests, eradication, N.Y.State 351.

**Brassolis sophorae—**

parasitism of egg by *Telenomus nigro-covallii*, 824.

pupal respiration, 502.

Braxy in Iceland, 243.

Brad—see also Flour.

acetylmethylcarbinol in, relation to bread flavor, 878.

consumer preferences for, U.S.D.A. 716

making, bound water in, 437.

special, U.S.D.A. 579.

staling, theories and problem, 271.

*Brevicoryne brassicae*, see Cabbage aphid.

Bricks, Virginia manufactured, merits and classification, 858.

Bridges, sliding bearings for, coefficients of friction, determination, U.S.D.A. 700

Brines from oil-bearing strata in eastern Kentucky, iodine and bromine in, Ky. 130.

Briquettes made from agricultural waste products, properties, 403.

Brome, soft, vegetative vigor and possibility of cross-fertilization, 178.

**Bromegrass—**

awnless, feeding value of hay from, 609.

v. wheatgrass in Montana, Mont. 181.

**Bronchitis, infectious—**

cultivation of virus, 696.

definition, 396.

*Brontispa froggatti* on coconut, 215.

Brown-tail moth, notes, 64; U.S.D.A. 654.

**Brucella—****abortus—**

dissemination by udderless cows, 249.

examination of pasteurized and un-pasteurized milk for, 249.

in feces and urine of cows, 849.

Infection, effect on milk yield of cows, 386.

injections into heifer calves, results, 693.

isolation from blood stream of cattle, 102.

suspension standardized by a dry standard antiabortus serum, 392.

cells, chemistry of, Mich. 689.

group, nonspecific agglutination in, Mich. 689.

group, serologic classification, 98.

persistence in aborted fetus and its membranes, 849.

polysaccharide extracts, precipitin and complement-fixation reactions, 98.

strains isolated in Minnesota, differential study, 98.

**Brucella—Continued.**

*suis* infection of brain of swine, 895.

*suis* infection of swine, unusual case, U.S.D.A. 688.

**Brucelliasis—**

bibliography, 247.

of swine, 589.

*Bruchus bruchialis*, see Vetch bruchid.

Buckeye, California, distribution, relation to honey production, U.S.D.A. 655.

**Buckwheat—**

acreage, yield, and production, revised estimates, U.S.D.A. 713.

and buckwheat flour, production consumption balance, Mich. 709.

effect of manganese and copper, 761.

**Buffalo grass seed—**

harvesting, design of machine for, 114.

production and germination, Tex. 469.

Buffalo in Alaska, U.S.D.A. 500.

**Buildings—**

high, insects on roofs of, 823.

settlement records and loading data, 401.

Bulb diseases, [N.Y.] Cornell 804.

**Bulb mite—**

notes, U.S.D.A. 654.

on tuberose, heat treatments for, 80.

Bulbous plants, virus mosaic or stripe disease, 194.

Bulbs for planting in western Oklahoma, [Okla.] Panhandle 632.

Bull, dairy, management and feeding, Ill. 239.

Bull indexes, [N.Y.] Cornell 841.

**Bulls—see also Sires.**

type, relation to birth and weaning weight and rate of gain of progeny, Mont. 669.

*Bunostomum trigonoccephalum*, notes, 394.

Bunt, see Wheat smut, stinking.

**Butter—**

catalase test, relation to quality score or keeping quality, 532.

churning loss and keeping quality, effect of neutralizers, 528.

clarified, old native and new methods of making, 95.

cold-stored, diacetyl in, 387.

cultures, oxidation of acetylmethylcarbinol to diacetyl in, Iowa, 94.

effect on fecal output of Ca in rats, 563.

*Escherichia-Aerobacter* species in, 528.

fishy flavor in, repasteurization of cream as preventive, 388.

internal and subsurface discolorations, 95.

keeping quality, relation to acidity of cream, U.S.D.A. 528.

lactic acid in, determination, [N.Y.] Cornell 841.

musty flavor in, cause, 532.

packed in boxes of different types, rate of temperature change, 532.

**Butter—Continued.**

- physical properties, photomicrographic study, Mo. 679.
- prices, retail and wholesale, [N.Y.]Cornell 863.
- quality, improvement, Calif. 841.
- quality, relation to amino nitrogen in, S.Dak. 682.
- rancidity in, development, 527.
- spreadability, factors affecting, 528.
- surface molding, 95.
- United States imports of, factors affecting, [N.Y.]Cornell 863.
- vitamin A value, factor in soybeans affecting, 526.
- yield and composition, effect of silage, 237.

**Butterfat—**

- color of, 240.
- content of milk, unusual variation in, 237.
- electrokinetic potential, 527.
- farm prices, [N.Y.]Cornell 863.
- feeding to dairy cows, 237.
- percentage and production, heritability in data for proved sires, 175.
- percentage in milk, effect of coconut oil meal and palm-kernel oil meal, [N.Y.]Cornell 841.
- percentage in milk from Shorthorn type cows, 89.
- production, breeding for, U.S.D.A. 528.
- production of cows possessing supernumeraries, 177; Mo. 679.
- seasonal variation in, 387.
- secretion, factors affecting, 240.
- test, variation in, cause, [N.Y.]State 237, 844.
- vitamin A in, Mich. 679.

**Buttermilk—**

- cultured, improvement, Calif. 841.
- supplemental value for pigs on rye pasture, Ark. 667.
- testing with Minnesota reagents, results, 527.

**Butyric acid—**

- bacteria, lactose- and lactate-fermenting, 686.
- production by fermentation of molasses, P.R.Col. 4.

*Byturus unicolor*, see Raspberry fruitworm.

**Cabbage—**

- aphid, control with rotenone, Tex. 502.
- aphid, life history and control, 362.
- aphid, vector of bean-mosaic virus, 344, 659.
- breeding, [N.Y.]Cornell 790.
- Chinese, absorption of vitamin B from rice bran, Hawaii 877.
- fertilizer placement, N.Y.State 626.
- fertilizers for, Ariz. 38.
- green and white, vitamin G in, Tenn. 125.
- headed and nonheading forms, relative value as mineral sources, U.S.D.A. 715.
- insects affecting, Ind. 503.

**Cabbage—Continued.**

- iodine in, 421.
- looper, control, N.Y.State 656.
- looper, control with pyrethrum dusts, Colo. 501.
- looper, notes, U.S.D.A. 654.
- mosaic virus, 194.
- temperature requirements, Mont. 632.
- yellows, problem in New York State, N.Y.State 813.
- yellows resistant varieties, Mo. 625.

**Cabbageworm—**

- imported, control by parasites, 219.
- imported, notes, U.S.D.A. 654.
- studies, 830; Tex. 502.

Cacao shell, feeding to cows, effect on vitamin D content of milk, 681.

*Cacoechia argyrospila*, see Fruit tree leaf roller.

*Cactoblastis caetorum*, notes, 509.

**Cactus—**

- pricklypear, control, Tex. 469.
- pricklypear in Australia, control and eradication, 508.
- spineless, adaptation, growth, and use, Tex. 468.
- spineless, yield and nutritive value, Tex. 517.

Cadelle beetle, notes, Colo. 224.

Cake and cake-making ingredients, 560.

Cake, yellow sponge, making, effect of high altitude and other factors, Colo. 561.

**Calciferol—**

- constitution, 743.
- molecular shape, 744.

**Calcium—see also Lime.**

- absorption and retention on different diets, 274.
- and phosphorus in dicalcium and tricalcium phosphate, utilization by dairy cows, 526.
- arsenate, chemistry, N.Y.State 215.
- arsenate for codling moth control, 72.
- arsenate, studies, N.Y.State 656.
- arsenite as fungicide against cereal smut, 51.
- availability from typical foods, 129.
- carbonate hydrolysis, relation to alkalinity of calcareous soils, Ariz. 595.
- concentrations in solutions, potentiometric determination, 582.
- content of soils, Mo. 589.
- cyanamide as orchard fertilizer, Mich. 625.
- cyanamide for treatment of soil infected with *Heterodera schachtii*, 58.
- deficiencies, effect on various types of animals, Calif. 834.
- deficiency during pregnancy, effect on fetus, 888.
- deficiency of rats, effect, 129.
- exchangeable, in soils, determination, 294.
- in blood and in plant tissue, microdetermination, 372.
- in blood of pigs, 229.

## Calcium—Continued.

- in blood plasma of dairy cattle, 681.
- in nutrition, 881.
- metabolism of albino rats, effect of butter and margarine, 568.
- retention on soybean-egg powders and milk powders when fed to rats, 127.
- retention, relation to store of calcium in body, 882.
- sulfate, *see* Gypsum.

## Calendula—

- leaf spot in Virginia, U.S.D.A. 194.
- powdery mildews, U.S.D.A. 194.

California Station, notes, 142, 285.

California Station, report, 894.

California University, notes, 142, 285.

*Calliphora erythrocephala*, effect of environment, 664.

*Caloglyphus rodionovi*, heat and cold resistance, relation to temperature of development, 358.

## Calves—

- beef, fattening for market, Mich. 887.
- beef, winter rations for, Mo. 668.
- beef, wintering, supplements to North Park hay for, Colo. 516.
- blood chemistry and mineral metabolism, effect of solar ultraviolet radiation, Mich. 238.
- cod-liver oil and muscle dystrophy in, 526.
- cost of raising, W.Va. 842.
- creep-feeding grain to, effect on size and quality of carcass, W.Va. 835.
- development in Tropics, 682.
- growth and development on milk diet, Mo. 529.
- growth, effect of different calcium phosphorus ratios, 373.
- immunity produced by B. C. G vaccine, duration, 849.
- infectivity of tubercle bacilli from dung on pasture, 537.
- milk supplemented only with minerals and vitamins as sole diet, Mo. 679.
- mineral metabolism, 843.
- molasses and alfalfa supplements to grain rations for, Mo. 668.
- raising on calf pellets and starters, [N.Y.] Cornell 841.
- rations, vitamin A as whole milk substitute, 525.
- starters fed dry with limited whole milk, 528.
- tolerance to massive doses of cod-liver oil, U.S.D.A. 528.
- udder development, relation to milk-producing ability during first lactation, U.S.D.A. 528.
- vitamin D requirements, 288; Mich. 679.
- white spotted kidneys in, 851.
- winter, creep-feeding, Mo. 668.
- wintering in northern Great Plains, effect of different methods, U.S.D.A. 228.

Canaries, *Plasmodium otti* n.sp. from screech owl, infective to, 658.

Canna, edible, variety tests, Hawaii 780.

Canned fruits, discoloration, 744.

## Canning—

- crops, diseases of, N.Y.State 686.
- crops, insect pests, N.Y.State 656.
- home, costs, Wash. 717.
- home, of fruits, vegetables, and meats, U.S.D.A. 419.

jars, all-glass, vacuum determination in, 443.

of meat, recommendations for, U.S.D.A. 716.

work of Food Investigation Board of Great Britain, 877.

Cans, tin, corrosion by foodstuffs, 744.

Cantaloup, *see* Muskmelon.

## Capillaria—

*annulata*, notes, P.R. 856.

*annulata* earthworms as intermediate hosts, 823.

*hepatica* in house rats, 213.

*hepatica* of British muskrat, 652.

in fowls, descriptions and synonymy, 541.

infection of calves, 250.

*retusa*, notes, P.R. 856.

*Capitophorus* aphids infesting *Artemisia*, 659.

## Capons—

comb growth in, response to androsterone, 779.

production, Kans. 89.

Carbameone, action on intestinal trichomonads of rats, 392.

## Carbohydrates—

and proteins mixture in diet, effect on gastric secretion or digestion, 272.

in cotton plant at different growth periods and effect of fertilizers, 471.

in *Iridaea laminarioides*, 148.

in ration, effect on reproductive capacity of rats, 515.

metabolism in plants, 456.

of wheat plant, seasonal changes in, 768.

synthesis in softwoods, value of different wave lengths of light, Vt. 191.

Carbolineum emulsions for orchard trees, stability and dispersion, 645.

## Carbon—

accumulation in soil, Mo. 589.

disulfide, merits, Calif. 780.

fixation by plants, effect of atmospheric humidity on rate, 766.

in Iowa soil types, Iowa 8.

in soil, effect of rotation and manure, Utah 759.

organic, and oxidation value of soil organic matter, simultaneous determination, 582.

Organic, Committee, report, 583.

tetrachloride drenches for nematodes of sheep, 394.

tetrachloride, effect on sheep, 588.

- Carbonic—  
 acid estimation in soils, new apparatus for, 151.  
 anhydrase and photosynthesis, 315.
- Cardiac enlargement, reversion in a child following treatment for avitaminosis, 728
- Carolinata cypri*, notes, U.S.D.A. 654.
- Carotene—  
 absorption in intestinal tracts, 725.  
 and vitamin A metabolism of human fetus, 276.  
 and xanthophyll, determination by single distribution between liquid phases, 585.  
 content of wheat varieties in Northwest, 36.  
 effect on nervous disorder in rats fed diet low in vitamin A, 884.  
 in carrots, inheritance, 772.  
 in feeding stuffs, spectrophotometric data bearing on character of pigments, 526.  
 in feeds, relation to vitamin A activity, 836.  
 in hay stored at different seasons, rate of decomposition, 526.  
 in Indian foodstuffs, 725.  
 in leaf extract, spectrophotometric determination, 296.  
 in leafy vegetables during storage, 725  
 preservation in silage and biological properties of milk, 526.  
 requirements of livestock, Calif. 834; U.S.D.A. 528.
- Carpet beetles, notes, U.S.D.A. 655.
- Carpocapsa pomonella*, see Codling moth.
- Carrot blight, spraying tests, Tex. 488.
- Carrot diseases, Ariz. 46.
- Carrots—  
 carotene in, inheritance, 772.  
 fertilizers for, Ariz. 38.  
 improvement, Calif. 790.
- Casein—  
 and paracasein solubility, effect of salts, 293.  
 deaminized, anemia of, 849.  
 plastics, studies, N.Y.State 579.  
 purified vitamin-free, lactoflavin as contaminant, 742.  
 solubility, effect of salts, 686.  
 synthetic fibers resembling wool from, U.S.D.A. 528.
- Caseinogen—  
 dietary, effect in prevention of fatty liver, 572.  
 in diets, effect on nature of cholesterol fatty liver, 571.
- Cassava—  
 mosaic disease, transmission, mechanism, 805.  
 varieties and strains, composition, P.R.Col. 31.  
 variety tests, Hawaii 780.
- Castor-bean tick, relation to its physical environment, 834.
- Catalase test, application to butter, 532.
- Cataphoresis in soil science, 592.
- Cataract—  
 dinitrophenol, effect of ascorbic acid administration, 135.  
 nutritional, susceptibility of strains of rats to, 573.
- Catbirds, food habits, 357.
- Cats, new nematode from, 64.
- Cattle—see also Calves, Cows, Heifers, Live-stock, and Steers.  
 Alaskan hybrid Holstein-Galloway, birth weight, gestation period, and sex ratio, 176.  
 and yaks, hybrids, structure of testes, 774.  
 baby beef, winter finishing, Tenn. 81.  
 beef and dual-purpose, breeding, improvement in, U.S.D.A. 23.  
 beef and dual-purpose, records of performance, U.S.D.A. 667.  
 beef, breeding, feeding, and management studies, U.S.D.A. 667.  
 beef, feeding experiments, 228, 519.  
 beef, improvement, U.S.D.A. 667.  
 beef, live weight gains per acre on improved pasture, [N.Y.] Cornell 835  
 beef, molasses as feed for, La. 837.  
 beef, pasture v. dry lot for full-feeding yearling steers, Mo. 668  
 blindness in, two types, relation to vitamin deficiency, 525.  
 blood in health and during anaplasmosis, 535.  
 breeding, early history and importance of herd testing, U.S.D.A. 23.  
 breeding problems, Calif. 834.  
 carcass quality of heifers v. steers, Mich. 668.  
 cross-bred Galloway-Holstein, inheritance in, 176, 773.  
 dairy—see also Cows.  
 amount of grazing furnished by all year pasture, Tenn. 89.  
 breeding, feeding, and management Mo. 679.  
 calcium and phosphorus metabolism, Vt. 235.  
 carotene requirements of, U.S.D.A. 528.  
 corn silage as source of vitamin D, Mich. 238.  
 effect of increasing interval between milkings, Mo. 679.  
 feeding standards, proposed changes in, 236.  
 germ plasma survey, 175.  
 molasses as feed for, La. 837.  
 polythella in, 175.  
 respiratory rate, effect of environmental temperature in Tropics, 89.  
 silage crops for, Ill. 842.  
 sterility in, use of hormones in combating, [N.Y.] Cornell 777.  
 disease, new, further outbreak, Tex. 533.

## Cattle—Continued.

- evaluating inheritance for type from germ plasim survey, 175.
  - fattening, effect of type and age, Mich. 228.
  - feeder, costs and yields, Mich. 708.
  - feeding experiments with red clover silage, 669.
  - finishing in barn and on pasture, Ky. 81.
  - foraging habits, Ariz. 80.
  - genetics, of, 773.
  - grazing, measuring pasture yields with, 671.
  - hairs, black and red pigment in, distribution, 19.
  - hemorrhagic disease in, Nev. 243.
  - herd improvement data, Vt. 284.
  - Hereford, adaptability to east Texas, Tex. 516.
  - horned, and yak hybrids, blood elements in, 176.
  - in Kenya Colony, weights of carcass and of individual organs, 519.
  - Indian, silver gray color in, 774.
  - Jersey, results of close breeding, 175.
  - loin disease, studies, Tex. 533.
  - manner of heat disposal by, effect of plane of nutrition, 85.
  - marketing age, Mont. 708.
  - mineral requirements, Tex. 516.
  - minimum mineral requirements, 374.
  - monsters in, experiments with Dexter and Telemark crosses, 774.
  - on phosphorus-deficient diet, effect of phosphorus and calcium supplements, 372.
  - plague, *see* Rinderpest.
  - poisoning, *see* Plants, poisonous, and specific plants.
  - reproduction in, 837.
  - screw tail in, inheritance, 317.
  - semi-hairlessness in, inheritance, 176.
  - unicorn, production by transplantation of horn bud, 317.
  - vitamin A requirements, Calif. 834.
  - wintering inside and outside in Scotland, 672.
  - young, deficiency disease in Western Australia, 250.
- Caudal vertebrae in mice carrying T gene for brachyury in crosses, 317.
- Cauliflower—
- browning, control, 491; [N.Y.]Cornell 804.
  - mosaic diseases, Calif. 804.
  - root rot, studies, 818.
- Cavies and rabbits, periodicals on, U.S.D.A. 356.
- Cedar, eastern red, cubic volume table for, 45.
- Cedar rust, *see* Apple rust
- Celama sorghicella*, *see* Sorghum webworm.
- Celery—
- fibers or strings, structure, Calif. 790.
  - Fusarium* yellows, notes, Mich. 635.
  - insects affecting, Ind. 503.

## Celery—Continued.

- late blight, control, 814.
  - loss of weight during marketing, factors affecting, 627.
  - temperature requirements, Mont. 682.
  - virus diseases, Calif. 804.
- Celiac diseases in children, treatment, 889.
- Cells—*see also* Plant cells.
- combustion in presence of potassium and phosphorus in, raising, 15.
- Cellular—
- immunity, grades of resistance or susceptibility, 46.
  - structure, modifications by ultraviolet rays, procedure for study, 311.
- Cellulose—
- chemistry of, 178.
  - studies, U.S.D.A. 579.
- Cement, corrosion, 700.
- Cenangium populeum*, notes, 819.
- Centrifuge, high speed vacuum for filtrable viruses, description, 389.
- Cephalin in yolk and developing chick embryo, 830.
- Cephalonomia waterstoni*, notes, Colo. 224.
- Ceratitidis*—
- capitata*, *see* Fruitfly, Mediterranean.
  - rosa* on citrus in western Transvaal, control, 215.
- Ceratomegilla fuscilabris*, bionomics, 228.
- Ceratostomella*—
- piovae*, cause of blue stain on pine, morphology and life history, 650.
  - ulmi*, persistence in stumps of Dutch elm diseased trees, U.S.D.A. 635.
  - ulmi*, recorded spread, extent of damage in Europe and America, and control, Conn.[New Haven] 649.
  - ulmi*, susceptibility of species and varieties of elms to, 68.
- Circospora*—
- calendulae* leaf spot of *Calendula* in Virginia, U.S.D.A. 194.
  - leaf spot of beets, control, Tex. 487.
  - leaf spot or blight of beets, differentiated from boron deficiency disease, 205.
  - liriodendri*, morphology and life history, 636.
  - spp. on grape leaves in Palestine, 647.
- Cercospora*—
- arachnoidea* n sp., description, 647.
  - herpotrichoides*, susceptibility of cereals and grasses to, 807.
- Cereal—
- diseases, notes, Mich. 635.
  - mixtures, seeded and harvested, changes in proportions of components in abnormal seasons, 618.
  - seed treatment, *see* Seed treatment.
  - smut—*see also* Grain smut and specific hosts.
  - dust fungicide tests for, 51.
- Cereals—*see also* Grain and specific grains.
- Coleoptera injuries to, 666.
  - genetic studies, [N.Y.]Cornell 780.

## Cereals—Continued.

grown under irrigation, rates of seedling, 474.

in France, *Fusarium* diseases of, 198.

rachitogenic factors in, 888.

susceptibility to *Cercospora herpotrichoides*, 807.

*Ceroplastes* spp., parasite collection, 502.

*Ceutorhynchus asenilis* in State of Washington, 666.

Cevitamic acid in milk, fresh or pasteurized, 727.

*Chabertia ovina*—

notes, 394.

pathogenic importance, 538.

*Chaetodacus ferrugineus dorsalis*, notes, 833

Chalcid flies—

revision of genus *Perilampus* and descriptions of new forms, 833.

second revision, U.S.D.A. 869.

*Chalcis annulata*, parasite of coconut caterpillar, 824.

*Chalodermus aeneus*, see Cowpea curculio.

Champagne, manufacture, 745.

*Charidryas myotis*, notes, 65.

## Cheese—

baby Gouda, effect of paraffin waxing, 687.

brick, composition and quality, effect of salt, 528.

Cheddar—

canning, Vt. 235.

made from clean milk, lactic acid flora of, 96.

making, chemistry of, 95, 388.

natural, canning, U.S.D.A. 529.

ripening, role of pepsin and rennet in, 96.

ripening, X-ray diffraction studies, 527.

cream, manufacture, Nebr. 389.

factories, inexpensive milk pasteurizing units for, 528.

industry in Italy, development and present status, N.Y.State 243.

Iowa blue, flavor and acidity, effect of *Penicillia*, 528.

Limburger, quality, factors affecting, N.Y.State 682.

making, curd firmness in, relation to curd tension, 388.

making, Holland's contribution to, N.Y.State 894.

manufacture, salting and cooking curds in, 528.

Neufchatel, manufacture, Nebr. 389.

processed, emulsifying salts used in, 687.

processed, wrappers for, 528.

ripening studies, 845.

Swiss, bacteriology, 687.

types, Bel Paese, Swiss, and Roquefort, manufacture, U.S.D.A. 529.

varieties, salting and cooking of curds in manufacture, N.Y.State 90.

*Othellopirura hamulosa*—

notes, P.R. 556.

of chickens and turkeys, Hawaii 820.

Chemicals, irritating effect, technic for determining, Mich. 246.

## Cherries—

breeding, N.Y.State 629.

development of fruits as affected by destruction of embryo, 836.

effect of carbon dioxide treatment on storage and transit diseases, U.S.D.A. 51.

fruit setting, Mich. 630.

pollination, Calif. 790.

pruning, cultural, and fertilizer tests, Colo. 476.

sour, soil culture, Mich. 625.

splitting in brine, 297.

spraying, high-calcium v. dolomitic lime bordeaux for, Mich. 189.

varieties, Colo. 476.

## Cherry—

aphids, induced immunity experiments, 353.

bacterial leaf spot and canker, Mo. 636.

buckskin, a virus disease, Calif. 804.

casebearer, hymenopterous parasites, 369.

casebearer, oviposition responses of, 71.

juice, studies, N.Y.State 579.

losses from diseases in 1935, U.S.D.A. 839.

maggots, control, N.Y.State 656.

mosaic in British Columbia, 496.

nursery disease, Mo. 636.

rootstocks, testing, N.Y.State 629; W.Va. 790.

## Chestnut—

bark, reaction to invasion by *Endothia parasitica*, 62.

black rot of fruits due to *Sclerotinia pseudotuberosa*, 649.

blight, induced immunity experiments, 353.

blight resistant varieties, Tenn. 38.

Chestnuts, preservation from molds, 649.

*Oncyletus eruditus* and *Alouroglyphus agilis*, interaction between, 213.

## Chick embryo—

development, variation in, 177.

feather development in, relation to sex, 675.

heartbeat of, rate and duration, thermal effect, 838.

lipoid phosphorus, lecithin, and cephalin distribution in, 838.

mature, mineral composition, 677.

new nutritional disease, 839.

reproductive glands and ducts, action of male and female hormones on, 20.

sex modification resulting from injections of male and female hormones, 778.

Chickens—see also Chicks, Fowls, Hens, Poultry, and Pullets.

broiler industry, commercial, economic survey, U.S.D.A. 868.

broiler production in winter, electric v. coal brooders for, Mich. 668.

## Chicks—

- baby, vaccination against fowl pox, Md. 105.
- body temperature, variability, 675.
- bone calcification, relation to vitamin D intake of parent stock, 878.
- calcium and phosphorus requirements. Tex. 517.
- colony houses v. battery brooders for, Hawaii 835.
- deformities in, due to toxic grain fed hens, 245.
- development, effect of incubator temperatures, 322, 381.
- effect of gonadotropic hormones, 614.
- eight-week weight and feathering, genetic differences, 675.
- gizzard erosion due to nutritional deficiency, 88.
- growth rate, Mo. 676.
- growth rate and effect of time of hatch. Mo. 668.
- livability, relation to length of incubation period, Mo. 668.
- metabolism studies, Mich. 668.
- milk feeding, 231.
- normal and deuteotomized, energy and gaseous metabolism, 523.
- normal, and with nutritional encephalomalacia, brain weight and moisture in, 232.
- pellagra like syndrome in, 839.
- protein rations for, high and low, Ky 81.
- protein requirements, Calif. 835.
- rations, Mich. 668.
- requirements for two new fat soluble vitamins, Calif. 834.
- respiratory disease caused by a filtrable virus, 106.
- Rhode Island Red down color, sexual dimorphism in, 612.
- sex control experiments, 617.
- slipped tendon, effect of curative material on plumage, Tex. 517.
- starting and laying rations, Ky 81.
- storage of vitamin D in, 233, 677.
- synthetic rations for, Mo. 668.
- trembling disease or epidemic tremors, N.H. 854.
- vitamin A requirements, 522, 676; Tex 517, 677.
- vitamin D requirements, Pa. 234; Tex 517.

## Children—see also Girls and Infants.

- food habits, voluntary, 722.
- growth, plotting graphic record, 562.
- health of, relation to vitamin D, 570.
- nutrition of, Mich. 721.
- oriental, growth in San Francisco, 721.
- physical examination, 130.
- preschool, magnesium needs, 883.
- preschool, nitrogen metabolism, 273.
- school, diet of, in Chorley, England, 130.
- Texas school, growth in weight and height, analysis of records, Tex. 561.
- white, physical growth, 879.

## Children—Continued.

- with and without endocrine dysfunctions, cholesterol metabolism in, 883.
- Chili pepper dehydrator, 862.
- Chillies, Indian, inheritance of pungency in, 174.
- Chilo simplex*, see Rice borer, Asiatic.
- Chilocorus similis*, blonemics, 228.
- Chinch bug—
  - biology, effect of sorghum and other hosts, 506.
  - control, Mo. 655.
  - eggs, incubation, 828.
  - flights, 862.
  - in southwestern Oklahoma, third generation and migration, 70.
  - notes, U.S.D.A. 654.
  - populations in Ohio, 70.
  - situation in Iowa, 64.
  - survey, Ohio 214.
  - winter mortality, temperature and moisture as factors, 829.
- Chinese—
  - men, nitrogenous metabolism, 420.
  - subjects, basal metabolism, 420.
  - subjects, copper balance experiments, 421.
- Chionaspis*—
  - furfura*, see Scurfy scale.
  - pinifoliae*, see Pine needle scale.
- Chlorates, toxicity, factors affecting, Calif. 780.
- Chlorine—
  - in blood and in plant tissue, microdetermination, 372.
  - solutions, activity, U.S.D.A. 528.
- Chlorophyceae and Heterophyceae of Oklahoma, 12.
- Chlorophyll—
  - a and b in leaf extract, spectrophotometric determination, 296.
  - determination by Lange colorimeter, 584.
  - in plants, measurement, 153.
  - in potato leaves, relation to chlorine, 171.
  - molecules, number comprising an absorption unit in photosynthesis, 171.
- Chlorophyllometry, 153.
- Chloropsis*, Nearctic species, synopsis, 664.
- Chlorosis—
  - effect of leaf injections, 789.
  - of fruit plants, control, 645.
  - of fruits, Calif. 803.
  - of grapevines, relation to soil reaction and composition, 647.
  - of pin oaks, 499.
- Choanotaenia infundibulum* in partridges, 252.
- Choerostrogylus pudendotectus*, ingestion of inflammatory exudate by, 895.
- Cholesterol—
  - free and combined, in bile, determination, 585.
  - heat-treated, absorption spectra and properties, 581.
  - heat-treated, provitamin D of, 82, 581.

**Cholesterol**—Continued.

metabolism in children with and without endocrine dysfunctions, 888.

**Choline**, distribution in tissues, 129.

*Chortophaga viridifasciata australior*, role in cotton wilt transmission, 809.

Christmas berry, California, thrips, biology, 508.

**Chromosome**—

configurations in some new oenotheras, 19.

fragment in corn, cytogenetic study, 771.  
structure X, X-ray experiment with, 608.

**Chromosomes**—

behavior in *Agrostis nebulosa*, 173.

behavior, relation to genetics of *Agave*, 609.

doubling in wheat, rye, and hybrids of these, 22.

5 and 9 in corn, revised linkage maps, 19.

number and species characters in *Yucca*, 22.

number in *Asclepias*, 173.

number in cultivated fruits, N.Y. State, 175.

number in *Dolichos lablab*, 20.

number in Malvaceae, 173.

number in rice, association and origin, 609.

number in sheep and goats, Tex. 463.

number in sorghum, 21.

number in yaks, 774.

of *Sphaerocarpos cristatus*, 174.

translocation, sex-linked, in *Apotettia eurycephalus*, 19.

**Chrysanthemum**—

leaf miner, control, 222.

leaf spot due to *Septoria obesa*, U.S.D.A. 635.

leaves, enzyme system, effect of shortening the day, 167.

*Chrysobothris femorata*, see Apple tree borer, flat-headed.

*Chrysomphalus aurantii*, see Red scale, California.

*Chrysomya americana*, notes, Tex. 502.

*Chrysopa* sp., predatory enemy of flower thrips, S.C. 217.

**Chrysops**—

genus, description and control, 77.

spp., see Deer flies.

Church, rural, see Rural.

Churning losses, factors affecting, 528.

Churns, large, energy consumption, 861.

*Oidoria acerina* n.sp., notes, 807; [N.Y.] Cornell 804.

Cicada, periodical, importance as insect pest, 70.

*Cicadulina storeyi* n.sp., description, 70.

**Cigarette beetle**—

control, 214.

control, effectiveness of fumigants, 367.  
notes, U.S.D.A. 654.

Cigars prepared with native and imported wrappers, burning quality, 187.

*Cimex lectularius*, see Bedbug.

*Cinara pseudoschwarzii* n.sp., description, 863.

*Cineraria* leaf spot disease, 818.

**Citric acid**—

determination in milk, 527.

isolation from potato tubers, 608.

small amounts in biological material, determination, 585.

Citrus—see also Lemons, Oranges, etc.

aphids, control, 70.

breeding new varieties, Calif. 790.

canker eradication, U.S.D.A. 634, 635.

composition, relation to soil nutrients, Calif. 790.

cyanide fumigation, Calif. 824.

diseases, control, 648.

fertilization, Calif. 790.

fertilization, summer, 759.

flowers, chemical composition, 799.

fruit products, U.S.D.A. 579.

fruit rots, prevention, Calif. 804.

fruits, ascorbic acid content, U.S.D.A. 715.

fruits, nitrogen content, seasonal changes in, 790.

fruits, vitamin C in, U.S.D.A. 715.

growth, effect of soil temperature, 798.

growth, relation to potassium, 482.

gum disease in Philippines, 62.

hybrids, cytology of chromosomes in, Tex. 476.

insect pests in Ceylon, 358.

insects in Jamaica, 66.

mites, notes, Tex. 502.

mottle leaf, a physiological disease, Calif. 803.

mottle leaf, treatments, 497, 816.

new forms, introduction, Hawaii 790.

oil sprays, Calif. 824.

phosphorus deficiency in, 336.

phosphorus nutrition, 603.

rootstock effects in, Calif. 790.

rootstock resistance to root rot, Tex. 488.

rootstocks of, Tex. 476.

rust mite, control, U.S.D.A. 654.

scab fungus, perfect stage, 648.

stem-end rot, 498.

thrips, control, U.S.D.A. 654.

thrips on oranges, dusts tested against, 827.

tree decline, Ariz. 6.

trees, irrigation and fertilization, Ariz. 38.

whitefly, see Whitefly, citrus.

**Cladosporium**—

disease of hops, 636.

*fulvum* leaf mold, tomatoes resistant to, U.S.D.A. 193.

*fulvum* on tomatoes, temperature studies, U.S.D.A. 59.

herbarium, cause of subsurface discoloration of butter, 95.

*malorum*, notes, 490.

*ptisicolum* in Maine, U.S.D.A. 839.

- Clarkias, greenhouse-grown, rust on, U.S.D.A. 803.
- Clausena lansium* anthracnose in South China, 643.
- Claviceps paspali*, notes, 643.
- Clay—  
adsorption of liquids by, 593.  
Cecil, sheet erosion studies, Ala. 544.  
fractions, properties, 591.  
hydration, surface behavior, Mo. 589.  
hydroxyl groups, properties as basis for characterizing mineral soil, 449.  
marine, consolidation, 402.  
Putnam, base-exchange reactions, behavior of polyvalent cations in, 448.  
soils, properties and behavior, 402.  
substance of soils, identification by X-rays, 591.
- Clematis recta* aqueous extracts, bactericidal and fungicidal action, effect of fertilizers, 818.
- Climate—  
in Kenya, effect of forests, 750.  
Moscow Laboratory of, notes, 143.  
plant, comparative measurement of temperature, 750.
- Climatic—  
map of Czechoslovakia, 6.  
maps of North America, 444.
- Climatological data, U.S.D.A. 156, 301, 588.
- Climatology, handbook, 750.
- Clostridium*—  
*botulinum* type C, relation to duck sickness in Alberta, 108.  
*oedematis*, control, 537.  
*oedematis-maligni*, notes, 536.  
*ovatoicum*, control, 537.  
*saccharobutyrium*, proposed name, 686.  
*tyrobutyricum*, notes, 389.  
*tyrobutyricum*, proposed name, 686.  
*welchii*, effect of toxins of substance in normal intestine, 849.  
*welchii* toxins, physiological actions, 849.  
*welchii* type C from sheep in North Wales, 393.
- Clothes moth, webbing, development, effect of humidity, 71.
- Clothes moths—  
biology and control, [N.Y.]Cornell 820.  
breeding, 863.  
control, U.S.D.A. 501.
- Clothing—  
selection and care, 140.  
textbook, 284.
- Clover—  
bur, variety tests, Tex. 468.  
growth, effect of meteorological factors, 445.  
hop, injurious effects on stands of *Lespedeza sericea*, Tenn. 29.  
pasture, time for seeding, Vt. 178.  
red, and grass mixture harvested at different stages, nutritive value, 836.  
red and alsike, fertilizer experiments, N.H. 469.
- Clover—Continued.  
red, anthracnose resistance of, Ky. 46; Tenn. 46.  
red, seed production, relation to insects, 657.  
red, variety tests, Ky. 29.  
red, visited by bees, relation to tongue length, 225.  
seed, production-consumption balance, Mich. 709.  
sweet, see Sweetclover.  
variety tests, Tex. 468.  
white, culture for pasture and for seed, U.S.D.A. 470.
- Club work, see 4-H club.
- Onephasia longana*, see Strawberry fruit-worm.
- Cobalt chloride and nickel chloride for wasting disease, 250.
- Cocci, acid-proteolytic, acid production and protein degradation in foremilk and in rennet extract, 242.
- Coccidia—  
in chicks, effect of calcium carbonate additions, 696.  
infection, relation to vitamin G, 691.  
of wild rats, 212.
- Coccidiosis—  
in chickens, 675, 696, 856.  
of domestic animals, effect of hardware cloth floors, Mich. 689.
- Coccidophilus citricola*, notes, 357.
- Cocciophagus*—  
*lycimnia* eggs and larvae, sexual dimorphism, 834.  
reproduction phenomenon in, 833.
- Coccus mangiferae*, injurious to mango flowers and fruits, 71.
- Cochliomyia* spp., see Screwworms.
- Cockchafters in Varese Province, 824.
- Cockerels—  
composition, effect of diet, range, and fattening, 877.  
development of body organs, effect of alfalfa meal, 229.
- Cocklebur seeds, germination and development of dormancy in, 171.
- Cockroach—  
American, penetration of gaseous pyridine, piperidine, and nicotine into body, 216.  
oriental, coagulation in blood, inhibition, 361.  
oriental, effect of toxic substances upon blood cell count in, 361.
- Cockroaches, control, U.S.D.A. 501.
- Coconut—  
caterpillar, parasitism of egg by *Tele-nomus nigrocoalis*, 824.  
oil meal, effect on percentage of fat in milk, [N.Y.]Cornell 841.  
pests, 215.
- Cod-liver oil—  
and muscle dystrophy in calves, 526; [N.Y.]Cornell 835.

## Cod-liver oil—Continued.

concentrate, feeding to calves, effect, Vt. 285.

in calf rations, 525.

## Coddling moth—

bait trap experiments, Mo. 655.

bait traps, cerambycids captured in, 501.  
bands, chemically treated, variations in effectiveness, 661.

biological studies, Mo. 655.

biometrics and control, Del. 655.

brood study for one decade, 71.

control, 220, 501, 661, 830; U.S.D.A. 654; W.Va. 824.

control, chemically treated bands for, 826; Pa. 73.

control in arid region, 72.

control in Department of Puy-de-Dome, 661.

control in Michigan, eight seasons' tests, 71.

control, light traps for, value, N.Y.State 216.

control, new method, 72.

control, orchard sanitation for, large scale test, 74.

control, pruning as aid, 826.

control with nonarsenicals, 823.

control with zinc arsenate, Mich. 655.

cost of control, 826.

eggs and young larvae, effect of cold storage, 510.

experimental spraying, results, 823.

halowax (chlorinated naphthalene) as ovicide for, 363.

injury, variations in northwestern Arkansas, Ark. 655.

insecticide experiments, Mich. 509.

insecticides, field methods for study, 510.

larvae, methyl bromide fumigation, 501.

larvae, rearing for testing insecticides, 216.

larvae, toxic action of chemicals on, Mo. 655.

on apple, N.Y.State 656.

on pears, Calif. 824; N.Y.State 656.

on walnuts, Calif. 824.

phototropic responses, N.Y.State 656.

problem on Eastern Shore, 823.

spray tests, 826.

sprays, substitutes for lead arsenate in, 73.

sprays, timing by moth emergence, Mo. 655.

status, 71.

studies, 65.

## Coffee—

berries, chemical composition, effect of fertilizers, Hawaii 790.

bug, variegated, in Uganda, 218.

die-back, control, 648; Hawaii 790.

fertilizer requirements, Hawaii 790.

insects, control, U.S.D.A. 654.

leaf miners, parasites of, 508.

plantations in Puerto Rico, survey, P.R.Col. 412.

*Colaspis hypochlora*, notes, 824.

*Colcophora*—

*hemerobiella*, morphology, biology, parasites, and control, 830.

*malivorella*, see Pistol casebearer.

*pruniella*, see Cherry casebearer.

Coleoptera injurious to cereals, 666.

Collards, fasciation in, Tex. 488.

*Colletotrichum*—

*falcatum*, physiologic specialization in, 494.

*phomoides* on tomatoes, temperature studies, U.S.D.A. 59.

## Colloidal—

substances, chemotropic stimulation of roots by, 768.

systems, base exchange and stability of, Mo. 589.

## Colloids—

of great soil groups, neutralization curves, U.S.D.A. 753.

soil, affinity for cations and anions, 592.  
soil, flotation applied to study, 593.

soil, intensity of removal of added cations from by electrodialysis, 160.

soil, structure, 592.

soil, studies, Calif. 752; U.S.D.A. 589.

## Colon-aerogenes group—

indol tolerance of strains, 691, 770.

of bacteria, fermentation of pyruvic acid by, 4.

of bacteria, methylene blue reduction and oxidation-reduction potential studies, 149.

## Colon—

group of bacteria, hydrogen sulfide production as differential test, 312.

groups of bacteria, relation to soft rot, W.Va. 804.

organisms in milk, detection, evaluation of media, 684.

organisms in milk, heat resistance, 527.

## Color—

and size in mice, association, 776.

inheritance in gram, 462.

inheritance in swine crosses, 774.

inheritance of cross-bred Galloway-Holstein cattle, 176.

Colorado Station, report, 575.

## Colostrum—

of goat, composition and changes in, Mo. 679.

vitamin A in, 241.

## Colts—

draft, development, liberal v. limited rations for, Mich. 668.

minerals for, [N.Y.]Cornell 885.

Columbine borer, biology and control, [N.Y.] Cornell 820.

## Combines—

harvesting with, U.S.D.A. 860.

small, performance studies, 405.

Communities, mutualistic, in America, survey, 557.

Community and neighborhood groupings in Knott County, Ky. 713.

- Concrete**—  
 curing for resistance to alkali, U.S.D.A. 542.  
 plain, treatise, 402.
- Conenose bugs, natural infection of American human trypanosomiasis in, 247.**
- Conifer**—  
 blight, control, Tex. 488.  
 seedlings, *Fusarium* stem and root blight, Tex. 488.
- Conifers, lethal high temperatures and cooling effect of transpiration, 191.**
- Coniophora cerebella*, protecting wood against, 650.**
- Coniothyrium***—  
 disease of peonies, U.S.D.A. 46.  
*fueckeltii*, notes, 497.
- Connecticut [New Haven] Station**—  
 notes, 285.  
 report, 733.
- Conopia exittosa*, see Peach borer.**
- Conotrachelus nenuphar*, see Plum curculio.**
- Conotrachelus* sp. infesting nuts, 78**
- Consumer purchasing, scientific, 141.**
- Contarinia***—  
*pyricora*, see Pear midge.  
*sorhicola*, see Sorghum midge.
- Cooperative**—  
 associations and clubs, consumers', organization and management, 871.  
 associations, membership relations, 871.  
 associations, types in United States, 871.  
 credit unions, rural, 551.
- Cooperia***—  
*cuticlei* infestation in Saanen goats fatal effect, 104.  
 infection of calves, 250.
- Copper**—  
 as supplement to iron in hemoglobin formation, availability from various sources, 723.  
 content of milk through season, relation to anemia development in rats, 275.  
 determination, Mich. 579.  
 determination in liver, 295.  
 dusts for treatment of excoriosis of grapevines due to *Phoma flacida*, 647.  
 effect on plant growth, Ky. 7.  
 fungicide, new, 197.  
 fungicides, stickers in, tests, 807.  
 in animal tissues, 130.  
 in blood of normal infants of different ages, variations, 421.  
 in human tissues, 130, 421.  
 in stomach and liver preparations, 421.  
 lime spray complexes, decomposition, 489.  
 metabolism in man, 421.  
 oxide, red, as spray and dust fungicide, Mo. 686.  
 plant response to, 761.  
 role in plant nutrition, 459.  
 selenite as catalyst in Kjeldahl nitrogen determination, 749.
- Copper—Continued.**  
 sprays, insoluble, spreader materials for, 842.  
 sulfate and lime-sulfur for *Neospora* infection of peach trees, comparison, 647.  
 sulfate as plant nutrient, Del. 589.  
 sulfate for control of gastrointestinal parasites in sheep, W.Va. 849.  
*Coptotermes vastator*, biological study, 658.  
*Cordylobia*, revision of genus, 77.  
*Coreopsis* blights, Tex. 488
- Corn**—  
 acreages, yields, and total production, U.S.D.A. 712.  
 adaptability for ensiling, Ill. 842.  
 and grain sorghums, comparison, Tex. 468.  
 and hog industry in Iowa, economic effects, 555.  
 and legumes, interplanting, Ark. 617.  
 atypical growths occurring as mosaics, 19.  
 bacterial wilt, U.S.D.A. 198.  
 bacterial wilt, relation to weather conditions in Michigan and Indiana, U.S.D.A. 46.  
 borer, European—  
   in New Jersey, N.J. 510.  
   insecticides for control, Conn.[New Haven] 733.  
   laboratory rearing of larvae, 75.  
   metabolism at temperatures below zero, 823.  
   notes, U.S.D.A. 654.  
   resistance of selected strains of corn to, 75.  
   situation in Wisconsin, 363.  
 borer, southwestern, notes, U.S.D.A. 654.  
 borers, control, 823.  
 breeding, Calif. 780; Colo. 468; Ky. 29; Mo. 618; Tenn. 29; Tex. 468; U.S.D.A. 617.  
 breeding for tolerance to acid soil and low coumarin content, W.Va. 781.  
 brown spot, notes, U.S.D.A. 839.  
 canned, merchantable cream-style, microbiology, 441.  
 canning, costs, Wash. 717.  
 charcoal rot in Missouri, U.S.D.A. 808.  
 chromosome fragment in, cytogenetic study, 771.  
 commercial field, genetic variations in, 19.  
 cost of production, N.C. 119.  
 culture experiments, Ark. 617; Tex. 468.  
 cytogenetic studies, [N.Y.]Cornell 780.  
 diseases, notes, Mich. 685.  
 drought injury in inbred lines, method for studying resistance to, 471.  
 drying, 702.  
 dwarfism in, histological background, 771.  
 ear, drying, 861.  
 ear rot fungi, relative prevalence in 1933, 1934, and 1935, U.S.D.A. 635.

## Corn—Continued.

earworm, control, Ky. 65; N.Y.State 656; U.S.D.A. 654.  
 earworm, oviposition on silks of corn, Va. 662.  
 earworm, rearing, method, 501.  
 earworm, studies, 824, 831; Md. 831.  
 earworm, trapping, possible effect, Tenn. 65.  
 effect of potassium iodide on, Ky. 7.  
 effect on succeeding crops, Tex. 468.  
 fertilizer experiments, Ky. 29; Tex. 469.  
 fodder and silage, drought-stricken and river-bottom, composition and feeding value, Mo. 668.  
 fodder and stover, storage, 549.  
 for silage, breeding, [N.Y.]Cornell 780.  
 for silage, tests, Ga. 323.  
 frozen-pack, micro-organisms in, numbers and types, 878.  
 genetic and cytological relations, Tex. 468.  
 genetic studies, Mo. 618.  
 germ meal, biological value for cattle, 236.  
 germinating, special equipment for, 787.  
 germination, vigor, and yield, effect of seed coat injury, 31.  
 gluten feeding, effect on titratable acidity of milk, 90.  
 gluten meal, nutritive value, [N.Y.]Cornell 835.  
 Golden Bantam, top-cross selections, Tenn. 38.  
 grain, feeding to baby bees, methods, Tenn. 81.  
 green manure for, Tex. 409.  
 growing States, farm management and marketing for, textbook, 715.  
 immature, germination, factors affecting, 783.  
 improvement, U.S.D.A. 26, 617.  
 inheritance studies, Tex. 468.  
 kernels, water absorption by endosperm and embryo, comparison, 787.  
 leaf aphid, notes, U.S.D.A. 654.  
 leafhopper, notes, U.S.D.A. 654.  
 losses from diseases in 1935, U.S.D.A. 339.  
 maturity and bushel weight, relation, 180.  
 Mexican June and three other varieties, comparison, 470.  
 moldy, feeding, disease of horses caused by, 694.  
 nutrition studies, 456.  
 partially immune to witchweed, breeding, 639.  
 performance tests, Ill. 782.  
 production-consumption balance, Mich. 709.  
 production machinery, U.S.D.A. 542.  
 products of, 178.  
 protein content, effect of laboratory analyses and field replication, Colo. 783.  
 Research Institute of Iowa, 178.

## Corn—Continued.

response to irrigation, Ark. 617.  
 root aphid, distribution in South Atlantic States, 508.  
 root rots, control, Mo. 636.  
 rootworm, southern, studies, Ga. 358.  
 sap, exuded, at different stages of development, mineral composition, effect of soil treatment, Ga. 10.  
 seed, drier for, 861.  
 seedling blight, fungus causing, 341.  
 silage, *see* Silage.  
 stripe disease, phloem necrosis in, P.R.Col. 487.  
 sugar, mold fermentation products from, U.S.D.A. 579.  
 sugar, use in ice cream, 688.  
 sweet, *see* Sweet corn.  
 tillage methods in Missouri, economy of, Mo. 699.  
 ultraviolet radiation, genetic effects, 20.  
 varieties for North Carolina, N.C. 31.  
 variety tests, Ariz. 29; Ark. 617; Ky. 29; Tenn. 29; Tex. 468.  
 waxy gene in, biochemical studies, 20.  
 yield and acreage, relations, use of analysis of covariance in study, 407.  
 yield and stand, relation, 31.  
 yields, effect of summer soil-conserving crops on, U.S.D.A. 323.  
 yields, effect of winter soil-conserving crops, U.S.D.A. 324.  
 yields following summer cover, Fla. 323.  
 yields, increasing with vetch and Austrian winter peas, Ala. 28.  
 Cornell University, notes, 286, 576.  
 Cornstalk—  
   borer, notes, Tenn. 65.  
   disease in horses, 852.  
   disease of livestock, Colo. 97.  
   rots, studies, U.S.D.A. 634.  
 Corpora lutea—  
   prolongation in pseudopregnant rabbit, 321.  
   retrogression, effect of hysterectomy, 24.  
 Cortical hormone extract, effect on vitamin C in guinea pig organs, 423.  
*Corynebacterium*—  
   *perdicum* n.sp., description, 398.  
   *pyogenes*, studies, 244.  
*Coryneum* blight—  
   on almonds, Calif. 804.  
   on peaches, Calif. 803.  
*Coryza*, infectious—  
   of chickens, 675, 853; Calif. 849.  
   of chickens, clinical manifestations and transmissibility, 697.  
   of chickens, etiology, 697.  
 Cost of production, *see specific crops*.  
 Cotton—  
   acres, yields, and total production, U.S.D.A. 712.  
   American raw, distribution, U.S.D.A. 867.  
   American, sampling, U.S.D.A. 712.  
   and other malvaceous plants, comparative anatomy of seeds, 767.

## Cotton—Continued.

angular leaf spot and susceptibility of Acala variety, Ariz. 46.  
 bolls, mechanical snapping, Tex. 543.  
 breeding, Ariz. 29; Ark. 617; Tenn. 29; Tex. 468; U.S.D.A. 617.  
 breeding for disease resistance, Ga. 323.  
 burs, ground, v. cottonseed hulls in rations, Tex. 516.  
 carbohydrates in at different growth periods and effect of fertilizers, 471.  
 community production, U.S.D.A. 617.  
 cost of production, N.C. 119.  
 crown gall, Tex. 488.  
 culture experiments, Tex. 468.  
 diseases in Mississippi Delta, U.S.D.A. 193.  
 diseases in North Carolina, U.S.D.A. 635.  
 diseases in Peru, 642.  
 farms, high plains, organization and management, Tex. 552.  
 fertilizer experiments, Ark. 617; Tex. 469.  
 fertilizer placement tests, Tex. 11; U.S.D.A. 617.  
 fertilizers for, Mo. 589.  
 fertilizers, reinforcement with magnesium and calcium neutralizing agents, U.S.D.A. 617.  
 fiber, length-diameter relations, Ark. 180.  
 fiber length, variability in a relatively uniform strain, 784.  
 fiber, physical properties, measurement, Tex. 469.  
 fiber, studies, Ark. 618.  
 fibers, maturity and length, factors affecting, Ariz. 29.  
 flea hopper, studies, Tex. 502; U.S.D.A. 654.  
 foliage diseases, effect of sulfur or Cuproclde, Tex. 487.  
 from X-rayed seed, Tex. 488.  
*Fusarium* wilt, Tenn. 46.  
 gin damage, relation to rainfall, N.C. 325.  
 ginning and wrapping rates and related data, U.S.D.A. 867.  
 gins as public utilities in Oklahoma, 407.  
 gins, economic problems, Okla. 866.  
 gins, notes, U.S.D.A. 542.  
 grade, color, and strength, effects of weathering in field, Tex. 469.  
 green manure for, Tex. 469.  
 harvesting, mechanical, Tex. 543.  
 harvesting studies by picking and snapping, Miss. 325.  
 Hemiptera attacking in Belgian Congo, 828.  
 improvement, U.S.D.A. 617.  
 industry and plant breeding, U.S.D.A. 26.  
 inheritance studies, Ariz. 29; Tex. 468.  
 insects in Tanganyika, 502.  
 insects, little-known, 502.  
 irrigation tests, Tex. 468.

## Cotton—Continued.

leaf worm, notes, Tenn. 65.  
 leaf worm, role in cotton wilt transmission, 809.  
 long-staple, ginning, improved methods, U.S.D.A. 617.  
 losses from diseases in 1935, U.S.D.A. 339.  
 marketing, cooperative, early developments in, 712.  
 measuring fiber properties and lint studies, Tenn. 29.  
 nutrition and fertilizer studies, Ga. 323.  
 plant, genetical, physiological, and pathological study, Ark. 635.  
 plant, plosity, relation to adherence of dusted calcium arsenate, 503.  
 plant, transport in, 767.  
 planters, calibration of, Tex. 543.  
 planting mechanisms, calibration of, Tex. 548.  
 plants, effect of crazy top disorder and control by irrigation management, U.S.D.A. 201.  
 plants, resistance to stem weevil, nature of, 666.  
 price, Oklahoma farm, relation to price of futures at New York, Okla. 408.  
 production in Panhandle, [Okla.] Panhandle 620.  
 production machinery, U.S.D.A. 542.  
 program of AAA, effect on tenant, cropper, and laborer, 714.  
 purchasing power, relation to AAA reductions, 551.  
 response to irrigation, Ark. 617.  
 root aphid, notes, U.S.D.A. 654.  
 root rot, studies, Tex. 487, 488; U.S.D.A. 634.  
 root rot, Texas, control, Ariz. 46.  
 row competition, relation to varieties of unlike growth, 620.  
 sea-island, in Puerto Rico, relation to production in continental United States, P.R. 32.  
 seed, *see* Cottonseed.  
 situation, Okla. 408.  
 thrips damage, S.C. 217.  
 varieties adapted to mechanical harvesting, development, Tex. 468.  
 varieties, improved, registration, 620.  
 variety tests, Ark. 617; Mo. 618; Tenn. 29, 180; Tex. 468.  
 variety tests, margin effect in, 26.  
 whole, as source of oil and alpha-cellulose, 178.  
 wilt, distribution, role of insects in, 809.  
 wilt, effect of potash, 201.  
 wilt, significance for Peru, 201.  
 wilt, studies, Ark. 635.  
 wilt survey in Georgia Coastal Plain area, U.S.D.A. 635.  
 yarn, converting skein strength to strength of specified yarn count, U.S.D.A. 430.

## Cotton—Continued.

yields after legumes interplanted in corn, Ark. 617.

yields, effect of summer soil-conserving crops, U.S.D.A. 323.

yields, effect of winter soil-conserving crops, U.S.D.A. 324.

yields, increasing with vetch and Austrian winter peas, Ala. 28.

Cottonbush ashes, fertilizing value for tobacco, Conn.[New Haven] 186.

## Cottonseed—

anatomy and microchemistry, Tex. 468.

and fertilizer, distribution and placement, factors of efficiency, Tex. 543.

artificially drying before ginning, effect, U.S.D.A. 114.

cake, prevention of deficiency disease in sheep and goats by, Tex. 517.

delinted and Ceresan-treated, planting, Tex. 488.

disinfection experiments, 491.

drying, U.S.D.A. 542.

for planting purposes, dust treatment, Tex. 642.

germination, effect of sulfuric acid, Tex. 487.

meal and hegarl fodder ration, physiological effect on dairy cows, 525.

meal and hulls for lactating dairy cows, Tex. 529.

meal and silage ration v. herd ration, hay, and silage, La. 529.

meal as protein supplement for fattening beef cattle, Ga. 370.

meal, feeding value for ewes and lambs, Md. 673.

meal poisoning of livestock, Colo. 97.

meal, supplemental value for pigs on rye pasture, Ark. 667.

oil, isolation of four allophanates, 148.

planting at varying and uniform depths, Tex. 543.

products, feeding to beef cattle, Miss. 837.

treated and delinted, planting, Tex. 468.

Country, *see* Rural.

## County—

funds, sources, Ark. 705.

government in Arkansas, characteristics and costs, Ark. 865.

government, problems, 551.

Covariance used to analyze relation between corn yield and acreage, 407.

## Cover crops—

for soil conservation, U.S.D.A. 179.

improvement of soils with, Calif. 780.

merits, W.Va. 179.

summer, effect on crop yields and soil, Fla. 307, 323.

summer, value, 757.

winter, comparison, Tenn. 29.

winter, sown in cotton middles, residual effects, Ark. 617.

## Cowpeas—

aphid, transmission of bean mosaic virus by, 659.

curculio, studies, Ga. 358.

root tubercles, formation and nitrogen in, 607.

## Cowpeas—

as soil-building crop, Calif. 780.

for seed and hay, variety tests, Ark. 617.

for summer forage, Calif. 780.

variety tests, Tex. 468.

Cows—*see also* Calves, Cattle, and Heifers.

after long time calcium and phosphorus balance trials, body analyses, 526.

conformation and anatomy, relation to producing ability, U.S.D.A. 528.

dairy, dried blood as source of protein, Mass. 843.

dairy, estimating profitableness, Mo. 383.

dairy, full v. limited grain feeding, Tenn. 89.

dairy, in tropics, 611.

dairy, soybean hay as sole roughage for, 526.

effect of excess bases in ration, 682.

fed hay and corn silage, quality and quantity of protein in concentrate ration, effect on production, [N.Y.] Cornell 841.

fed only silage and cracked soybeans, production of, 526.

feeding, La. 842.

feeding experiments with silage, 237.

Holstein, on roughage only, milk and butterfat yields, 526.

lactating, alfalfa-molasses silage v. alfalfa hay as roughage for, 528; Mich. 679.

lactating, ground v. unground grain for, Tex. 680.

maintenance, vitamin A requirements, Tex. 529.

milk production, *see* Milk production.

possessing supernumeraries, butterfat records, 177; Mo. 679.

Shorthorn, milk analyses of typical herd, 241.

simplified rations for, W.Va. 841.

udders, *see* Udder(s).

vitamin A requirements for reproduction and lactation, 525.

yield and cost of production, Mich. 708.

yielding milk of poor quality, effect of variations in feeding, 237.

## Coyotes—

research work in embryology with, U.S.D.A. 500.

trapping in Alaska, U.S.D.A. 356.

Cranberries, scooping and handpicking methods, 42.

## Cranberry—

bogs, use of bordeaux spray on, effect, 496.

fruit rots, control by spraying, 815.

**Cranberry—Continued.**

industry in Massachusetts, Mass. 412.

pectin properties, 298.

Crane fly larva attacking newly set strawberry plants, 357.

*Crataegus pruinosa*, forms, 13.

**Cream—**

acidity, relation to keeping quality of butter, U.S.D.A. 528.

bitter flavor in, causes, 527.

bottled, cream-plug formation in, U.S.D.A. 528.

churning, judging, proposed score card for, 528.

coliform organisms in, effect on quality, 93.

cooling, evaporation and spray systems, Kans. 531.

cooling, vacuum method, [N.Y.]Cornell 841.

effect of sunlight, 844.

market, viscosity, effect of milk treatment, 527; Vt. 235.

of tartar, precipitation rate from wine, 745.

quality, relation to amino nitrogen in, S.Dak. 682.

rancidity in, development, 527.

sour, cause of bitter flavor in, W.Va. 842.

whipping, instant, by aeration, 527.

whipping, properties and stability, factors affecting, Md. 93.

Creameries, farmers', financial management, effect of volume and prices, Iowa 869.

Creamery equipment, electric power requirements, 861.

Creatine-creatinine excretion in muscular dystrophy, 882.

**Creatinine—**

creatinine excretion in muscular dystrophy, 882.

excretion, determining basal energy metabolism from, 721.

relation to body weight, Mo. 668.

Credit unions, cooperative, rural, 551.

Creeping Jennie, control, 330.

*Cremastogaster jehovae*, attendance on citrus mealybug of Palestine, 215.

Cresote-petroleum mixtures, initial toxicity to wood-destroying fungi, factors affecting, 859.

**Cricket—**

couleé, control, 858.

house, in Vancouver, 656.

Mormon, control, 358, 658.

Mormon, notes, U.S.D.A. 654.

*Cronartium ribicola*, see White pine blister rust.

**Crop—**

diseases, survey in Massachusetts, U.S.D.A. 339.

losses from diseases in United States, estimates in 1935, U.S.D.A. 339.

reports, U.S.D.A. 124, 414, 557, 870.

revisions on acreage, yield, and production, U.S.D.A. 712.

**Crop—Continued.**

risks, climatic index of, 751.

rotations, see Rotation of crops.

seeds, policy of registration, 624.

Cropping systems and livestock production on Iowa farms, interrelation, 551.

Crops—see also Forage crops and specific kinds.

adjustments in State, recommendations for, Mich. 708.

choice for saline land, U.S.D.A. 28.

composition, effect of replaceable bases in soil, 596.

cultivated, of British Empire and Anglo-Egyptian Sudan, 28.

for hill conditions, lamb fattening capacity, 178.

green manure for, Tex. 469.

improvement through disease control, [N.Y.]Cornell 804.

irrigation water requirements of, U.S.D.A. 617.

on muck soil, control, 824.

pollination and fertilization, rudiments of, 624.

production under severe soil-blowing conditions, N.Mex. 27.

statistical trends, Del. 707.

summer soil-conserving, effects, U.S.D.A. 323.

temperature requirements, Mont. 632.

time of irrigation tests, Colo. 468.

variety tests involving numerous varieties, new method of arranging, 26.

winter soil-conserving, effects, U.S.D.A. 323.

winter soil-conserving, yields, U.S.D.A. 324.

yields, effect of dates and methods of turning under winter soil-conserving crops and liming, U.S.D.A. 324.

yields, effect of summer soil-conserving crops, U.S.D.A. 323.

yields from Illinois soil experiment fields, Ill. 164.

yields in Germany, long-period prediction, 586.

yields, relation to effective precipitation, U.S.D.A. 6.

**Crotalaria—**

breeding, U.S.D.A. 617.

variety tests, Tex. 463.

**Crown gall—**

biology, 638.

growth, effect of temperature on, Ariz. 46.

on *Libocedrus decurrens*, Ariz. 46.

Cryolite, new form, 66.

Cryolite, progress of work with, Tenn. 65.

*Cryptolestes ferrugineus* occurring in *Trichogramma minutum* parasite laboratory, Colo. 224.

*Cryptolucilia*, parasites of, 511.

Cryptorchidism in swine, inheritance, 177.

*Cryptotermes* spp., biological study, 658.

- Cucumber—  
 beetle, striped, notes, 77; Ark. 655.  
 beetle, spotted, notes, U.S.D.A. 654.  
 beetles, attraction to buffalo gourd, 366.  
 diseases, virus, in Kwangtung Province, 195.  
 fermentation, Mich. 579.  
 mosaic virus 1, 194.  
 pickles, studies, U.S.D.A. 579.
- Cucumbers—  
 culture and preparation for shipment, P.R.Col. 791.  
 green flowered variation in, inheritance, 772.  
 in hotbeds, protection from bacteriosis, 492.  
 insects affecting, Ind. 503.  
 nitrogen nutrition and composition, relation to growth and fruiting, [N.Y.] Cornell 627.  
 storage, Tex. 476, 561.
- Cucurbit—  
 diseases, studies, Del. 635.  
 fruits, size differences in, histological basis, 19.
- Cucurbita moschata*, theory of hybrid origin for, 174.
- Cucurbits—  
 fungicides for, N.Y.State 636.  
 taxonomy and breeding, N.Y.State 629.
- Culex* mosquitos, vectors of fowl spirochetosis, 397.
- Cultivator—  
 two-row, converted into a weed control machine, S.Dak. 258.  
 universal type, designing, Mich. 699.
- Culture—  
 apparatus, universal, description, 811.  
 media for *Monilia* and molds, 173.
- Culture, human, forms and problems of integration, 264.
- Cuprocide, fungicidal properties, Tex. 487.

 in greenhouses, N.Y.State 636.  
 of seedlings, control, Mo. 636.  
 prevention, Calif. 804.
- Dandelions, petroleum sprays for, 37.
- Darso root rot, studies, U.S.D.A. 634.
- Dasymutilla* genus, revision, 869.
- Dasyscypha wilkommii*, new host for, 818.
- Date—  
 blights on inflorescence, Ariz. 46.  
 fruits, composition, Calif. 790.

## Date—Continued.

- fungus rot, spraying for, Ariz. 46.
- palm disease, Calif. 804.
- palm leaf spot due to *Graphiola phoenixis*, control, Ariz. 46.
- palms, propagation, Tex. 476.

## Dates—

- cultural studies, Ariz. 38.
- Deglet Noor, growth rate in metaxenia, 800.
- metaxenia and interspecific pollinations in, 800.
- pasteurization and storage, Ariz. 88.

*Datura*, gene for compound pollen grains in, 19.

*Davainea*—

- proglottina*, notes, P.R. 856.
- urogalli* in grouse, 252.

## Day length—see also Photoperiodism.

- changes, effect on enzymatic system of plants, 167.
- variation, effect on growth and dormancy of trees, 166.

Deciduomata, survival in unilaterally pregnant rat, 613.

## Deer—

- differential browsing on plats variously fertilized, 210.
- white-tailed, lungworms in, 398.

## Deer flies—

- in Arkansas, Ark. 221.
- of New York, 77.

Deguelin determination, Gross and Smith colorimetric method, 154.

Dehydration, see Drier.

Dehydroascorbic acid, antiscorbutic activity and storage, 888.

Delaware Station, report, 783.

*Dendroctonus*—

- brevicornis*, see Pine beetle, western.
- monticolae*, see Pine beetle, mountain.
- ponderosae*, see Black Hills beetle.

*Dendrophoma* spp., relation to fruit rot, 485.

*Deoclonia* sp., notes, 662.

Department of Agriculture, see United States Department of Agriculture.

*Dermacarus* n.sp., of British muskrat, 652.

*Dermacentor*—

- albipictus*, see Tick, winter.
- andersoni*, notes, 656.
- occidentalis*, see Tick, Pacific Coast.
- spp., vectors of equine encephalomyelitis, western strain, 104.

## Dermatitis—

- contagious pustular, of sheep, 849.
- due to vitamin B<sub>6</sub> deficiency and that of human pellagra, nonidentity, 136.
- effect of dextrin and sucrose, 137.
- in chicks and turkeys, relation to vitamins, Calif. 835.
- of the scalp of mice, 99.
- preventing factor in vitamin B complex, effect of reagents on, 81.

Dermatomycosis in guinea pigs, U.S.D.A. 688.

## Derris—

- and pyrethrum steepates, relative toxicity to potato insects, 66.
- as Japanese beetle repellent and insecticide, 223.
- chemical studies, U.S.D.A. 655.
- for control of vegetable insects, 824.
- tests with various insects in Dutch East Indies, 657.

Desert soils under irrigation from artesian wells, reclamation, Nev. 252.

Deserts, man-made, U.S.D.A. 111.

Desserts, frozen, notes, Ill. 878.

Desserts, frozen, quality and crystalline structure, relation to air conditioning, Mo. 679.

Detergents and detergency, 284.

## Devil's shoestring—

- as an insecticide, studies, 359; Tex. 502.
- growing and harvesting, U.S.D.A. 625.

## Dewberries—

- breeding, Tex. 476.
- effect of carbon dioxide treatment on storage and transit diseases, U.S.D.A. 51.
- spraying, Ky. 38.

Dextrose, use in ice cream, 528.

Dhobie itch, equine; a symptom of filariasis, 541.

Diabetes, advances in study and treatment, 573.

Diabetics, prescription diets, vitamin deficiency in, 729.

*Diabrotica*—

- duodecimpunctata*, see Cucumber beetle, spotted, and Corn rootworm, southern.
- vittata*, see Cucumber beetle, striped.

*Dialurodes*—

- chittendeni* control, oil spray tests, 507.
- chittendeni*, notes, 656.
- citri*, see Whitefly, citrus.

## Diamondback moth—

- control with pyrethrum dusts, Colo. 501.
- notes, U.S.D.A. 654.
- projected biological attack in New Zealand, 219.

*Diaprepes abbreviatus*, notes, 658.

*Diatraea grandiosella*, see Corn borer, southwestern.

*Diatraea saccharalis*, see Sugarcane borer.

*Dibrachys boucheanus*, egg placing by, description, 667.

Dicalcium and tricalcium phosphate, relative use by dairy cows, 526.

Dictionary, polyglottic, of plant names, 763.

*Dioryocaulus* from domestic and wild ruminants, 64.

*Dictyostellium discoideum*, ameoboid form, bactericidal activities, U.S.D.A. 596.

*Didinium* and *Paramecium*, interaction between, 213.

## Diet—see also Food and Nutrition.

- and diseases in fowls, 853.
- composition, relation to urinary excretion of ascorbic acid, 568.

## Diet—Continued.

effect on epidemic spread of infection, 245.

effect on vitamin C in rat organs, 727.

in relation to physical efficiency, 879.

of children, *see* Children.

of families of wage earners and clerical workers, 717.

of low-income families, 880.

of school children in Chorley, England, 130.

purified, for growth, reproduction, and lactation in rats, 881.

relation to gastric lesions in rats, 881.

stock, for rats, 722.

winter, of families in Nanking, 420.

## Diets—

American, economy and adequacy, U.S.D.A. 718.

basal, for vitamin B<sub>1</sub> assays, [N.Y.] Cornell 879.

English, studies, 719.

human, vitamin B<sub>1</sub> in, 724.

to fit family income, U.S.D.A. 272.

Dinitro-*o*-cyclohexylphenol for control of citrus red mite, Calif. 824.

*o*-Dinitrophenol, effect on vitamin C in guinea pig organs, 428.

*Diotoes eureka*, notes, 508.

*Diplocarpon earliana*, notes, U.S.D.A. 803.

*Diptodia*—

die-back of roses, symptoms and control, 498.

intraspecific and interspecific aversion in, 806.

*natalensis* attacking *Pandanus javanicus variegatus* in Alabama, U.S.D.A. 46.

*natalensis*, notes, 62.

on cotton bolls in Brazil, 642.

*Diprion*—

*polytomum*, *see* Spruce sawfly, European *sertifer*, notes, 80.

Diptera of medical and veterinary importance, 77.

Disease, quantitative aspects, 19.

## Diseases—

of animals, *see* Animal diseases and specific diseases.

of plants, *see* Plant diseases and specific host plants.

Disinfectants, practical value, phenol coefficient as measure, 689.

Disinfection and sterilization, 848.

*Dispharyna spiralis*, intermediate hosts, Hawaii 820.

*Disosteira carolina*, role in cotton wilt transmission, 809.

Distemper, control, U.S.D.A. 500.

Distillery slop for hogs, Ky. 81.

Documentation, recent developments in, editorial, 787.

Dodder on peppertrees in California, U.S.D.A. 808.

## Dog tick, brown—

*Babesia canis* in, life history and morphology, 227.

## Dog tick, brown—Continued.

household invasion by, 226.

vector of *Babesia canis*, 694.

Dogs, large breed, crosses, paralysis or pronounced weakness in posterior extremities, 775.

Dolomite, basicity, 759.

*Dontothorpea niger*, poison bait for, 513.

*Dosiostaurus maroccanus* in U. S. S. R., 217.

*Dothichiza populea*, notes, 818.

*Dothiorella* rot of avocados, Calif. 804.

Dough, fermenting, phenomena of gas evolution in, 438.

Dourine, diagnosis and control, U.S.D.A. 688.

Doves, immunogenetic studies of species and of species hybrids, 319.

Drain tile resistance to alkali conditions, improving, 857.

Drainage studies, Calif. 857.

## Drier—

electric, for fruits and vegetables, 116.

for chili peppers, 862.

for ear corn, 861.

for seed corn, 861.

walnut, brown type multistage, 406.

*Drosophila*—

*ampelophila*, *see* Pomace fly.

spp., relation to canning of tomatoes, Md. 882.

## Drought—

damage to shelterbelt prairie trees, Minn. 337.

injury in Arkansas in 1936, U.S.D.A. 635.

injury to ornamental trees, 483.

of 1934, effect on trees in Kansas, 157, 483.

of 1936, effect on Oklahoma farmers, Okla. 408.

refugee and labor migration to California, 865.

situation in southwestern Manitoba, 157.

## Droughts—

in New England, tree ring width as index, 600.

in United States, U.S.D.A. 445.

Drugs and foods, analyses, Conn.[New Haven] 272; Me. 272.

Dry cleaning, effect on strength of unweighted and of tin weighted silks, 891.

Drying—*see also* Fruits, drying, and Vegetables, drying.

commodity, basic principles involved in, 702.

methods and equipment, modern, description, 702.

natural, of forage crops, 702.

of farm products, 702.

## Duck—

nesting carrying capacities in Iowa, U.S.D.A. 855.

sickness in Alberta, relation to *Glaustridium botulinum* type C, 108.

wild, microfilaria in, 898.

## Ducks—

- in North America, parasite of, 398.
- mallard, raising, 211.
- mallards, semidomesticated, banding studies, 651.
- puddle, nests parasitized by ring-necked pheasant, 822.
- wild, 1935 international census, 211.
- wild, situation, U.S.D.A. 855.
- Z pack for, 525.

Dust explosion and spontaneous ignition of hay, U.S.D.A. 704.

Dust storms over Great Plains, causes and forecasting, 5.

Dutch whites, height, weight, and age tables for homogeneous groups, 561.

Dwarf mutation in rats, 177.

## Dyes—

- aniline, action on narcissus and beans, 640.
- bactericidal action, 50.
- fast, for agricultural fibers, U.S.D.A. 579.

*Dysdercus fasciatus* in *Acacia* savanna, food cycle, 69.

## Dysentery—

- chronic bacterial, *see* John's disease.
- in calves, treatment for, 851.

Ear tick, spinose, in India from horse bred in Australia, 667.

## Earth—

- pressure and relative density, relation, 401.
- slopes, stability, 401.

Earthworms as transmitters of *Capillaria annulata*, 823.

## Earwig, European—

- notes, Colo. 501; U.S.D.A. 654.
- parasitizing with *Bigonicheta setipennis*, 505.

Eating and drinking utensils, bacteriology, Mich. 689.

*Echerichia coli* resistance to radiation, 50

*Echinococcus* disease of domestic animals, 243.

*Echinotrips americanus* on cotton, S.C. 217

Economic conditions of Delta area, Utah 864.

Economics, teaching, present trends, relation to future value of research, 551.

Ectromella, experimental epidemiology, 245.

## Education—

- agricultural, *see* Agricultural education.
- higher, authority of State executive agencies over, 877.
- public, State provisions for equalizing cost, 417.
- research studies in, bibliography, 417.

## Elgrass—

- and other waterfowl food, U.S.D.A. 500.
- status and future prospects, U.S.D.A. 855.
- wasting disease, phytological investigation, 54.

## Egg—

albumin, *see* Albumin, egg.

cycle, effect of environment, Ariz. 81.

production—*see also* Hens, laying.

and egg weight, effect of age, W.Va. 836.

and hatchability, effect of vitamin D sources, 233.

and mortality, trend at Vineland contest, 524.

commercial, statistical study in Delaware, Del. 553.

control of environmental conditions, 675.

effect of backcrossing and reciprocal crosses, Ariz. 80.

effect of packing house byproducts in diet, 877.

high, breeding for, Del. 668.

persistency, inheritance of, 612.

relation to rate of mortality in hens, 88.

winter, effect of environmental conditions, 675.

yolk, lipoid phosphorus, iron, and copper in, Ky. 81.

## Eggplant—

bacterial wilt in fall plantings in Florida, U.S.D.A. 635.

chlorosis, Tex. 488.

diseases, virus, in Kwangtung Province, 195.

Eggplants, absorption of vitamin B from rice bran, Hawaii, 877.

## Eggs—

albumin index, determination by nomogram, 234.

ammonia nitrogen in, effect of storage conditions, 676.

ammonia nitrogen in, microdetermination, Mich. 154.

and poultry business, treatise, 678.

candling, factors affecting, Calif. 835.

consumption in rural Tennessee, Tenn. 414.

effect of cold storage and high temperature, Calif. 835.

feed-purchasing power, Mo. 705.

floating yolk in, nature of condition, 380, 381.

## hatchability—

correlation between egg weight, weight of total albumin, or weight of thick albumin, 380.

effect of packing house byproducts in diet, 877.

effect of tremulous air cells, 380; U.S.D.A. 612.

effect of variations in relative humidity, Hawaii 835.

relation to quality, 675.

relation to season and hour of laying, 875.

relation to vitamin G, 677.

in clutches, tendency of fowl to produce, effect of ovulation rate, 524.

**Eggs—Continued.**

- interior quality, genetic study, [N.Y.] Cornell 835.
- laid by one hen, feed-purchasing power, Mo. 668.
- market value, deterioration, causes, 88.
- marketing, Butler Egg Auction organization, Pa. 120.
- mold growth in storage, effect of humidity, [N.Y.] Cornell 381.
- of certain breeds, quality characters, variations, 676.
- of game birds, artificial incubation, [N.Y.] Cornell 821.
- percentage of unsalable and unusable, 675.
- pink white and olive yolk, cause, Calif. 835.
- preservation, 381; U.S.D.A. 579.
- quality after short storage periods, effect of temperature, humidity, and jarring, [N.Y.] Cornell 835.
- quality, albumin index as measurement, 234.
- quality, effect of climate and soil, 379.
- quality, inheritance of characters affecting, 465.
- size and quality, effect of iodine feeding, 524.
- storage of vitamin D in, 233, 677.
- storage quality, factors affecting, Ark 667.
- sulfur in, 525.
- temperature changes in, Mo. 668.
- vitamins B and G in, 677.
- work of Food Investigation Board of Great Britain, 877.
- yolk surface in, Mich. 235.

*Edamia viridescens*, repressive effects on red-leg disease of lettuce, 492.

**Elm—**

- Elm—*
- development of resistance to by chickens, age as factor, 251.
- oocysts, chicken as carrier, 107.

Elder twig canker, Tex. 488.

**Electric—**

- drier for fruits and vegetables, 116.
- lines, planning location, 407.
- motor-driven milk cooler, tests, 405.
- pig brooders, 862.

**Electricity—**

- and house wiring, handbook, 117.
- fencing with, 257.
- low voltage, generating, high speed wind-drawn propeller for, Mich. 256.

Electrification, farm, statistics, 860.

Electrodialysis, reclamation of alkali soils by, 450.

Electro-horticulture, commercial aspects, 256.

Elevators, farmer owned, in Ohio, financial operations, 556.

**Elm—**

- bark beetle—
- morphology, Conn.[New Haven] 224.

**Elm—Continued.**

- bark beetle—continued.
- native, notes, U.S.D.A. 654.
- smaller European, and Dutch elm disease, [N.Y.] Cornell 820.
- smaller European, notes, U.S.D.A. 654.
- cockscorn gall aphid, notes, Colo. 218.
- disease, Dutch—
- and lesser European elm bark beetle, [N.Y.] Cornell 820.
- eradication, 64; U.S.D.A. 46, 634.
- notes, [N.Y.] Cornell 804; U.S.D.A. 635.
- recorded spread, extent of damage in Europe and America, and control, Conn.[New Haven] 649.
- research at Willie Commelin Scholten laboratory, 63.
- seedling No. 24 resistant to, 63.
- status, U.S.D.A. 193.
- status in four eastern areas, 818.
- disease research, U.S.D.A. 634.
- honeydew aphid, notes, Colo. 218.
- leaf beetle eggs, parasite of, 357.
- leaf beetle, importation of natural enemies, U.S.D.A. 654.
- leaf-cluster louse, Colo. 218.
- leaf-roll aphid, notes, Colo. 218.

**Elms—**

- Cytosporina ludibunda* on, 818.
- species and varieties, susceptibility to *Ceratostomella ulmi*, 63.

**Elsinoc—**

- australis* n.sp., description, 498.
- favocetti* n.sp., description, 648.

Embankments, stability of foundations of, 401.

Embryos, culturing in aseptic media for study of tumors obtained by inoculation with *Bacterium tumefaciens*, 806.

*Emphytus cinctipes*, see Rose sawfly, curled.

**Empoasca—**

- fabae*, see Potato leafhopper.
- jaotatis*, studies, 828.

*Empria* spp., biology, 226.

*Empusa sphaerosperma* infesting onion thrips, 67.

Emulsions, technical aspects, 742.

**Encephalitis—**

- fox, development of immunity to, 99.
- fox, virus in upper respiratory tract, 541.

fox, virus, purification by tryptic digestion, 695.

fox, virus, types, 695.

toxic or nonvirus, of horses, 852.

Eucephalomalacia, nutritional, of chicks, effect of feeding vegetable oils, 232.

**Encephalomyelitis, equine—**

- comparison of strains, alteration and localization of virus, Nev. 243.
- infectious, transmission, U.S.D.A. 688.
- studies, 852; Colo. 533.
- susceptibility of gopher to, 104.
- virus, active immunization of guinea pigs with, 104.

- Encephalomyelitis, equine—Continued.  
virus-borne epizootic, studies, 541.  
western strain, arthropod vector for, 104.
- Encephalomyelitis of young chicks, N.H. 854.
- Encephalon cortex, producing lesions of, new technic, 821.
- Encyrtolophus tawensis*, role in cotton wilt transmission, 809.
- Endamoeba histolytica* of wild rats, 212.
- Endocrinology, practical applications to animal husbandry, 611.
- Endothia parasitica*—  
in chestnut trees, acquired immunity to, 353.  
reaction of chestnut bark to invasion, 62.
- Energy—  
metabolism and creatinine in urine, 721.  
utilization at different levels of protein intake, Mo. 515.
- Engineering—  
upstream, bibliography, U.S.D.A. 699.  
work of Food Investigation Board of Great Britain, 877.
- Engines—  
gasoline, cylinder wear in, 113.  
preflame reactions in, effect of tetraethyl lead, 701.
- Enteritis, ulcerative—  
discovery of organism, 398.  
in upland game birds, etiology, 398.
- Enterohepatitis, infectious, *see* Blackhead.
- Enterotoxemia—  
control by vaccination, 537.  
cows vaccinated against, transmission of antitoxic immunity to lambs, 103 in Tasmania, control, 537.  
of sheep, control, 537.
- Entomological—  
Commission of Kansas, enforcement of quarantine measures, 64.  
illustrating, 656.
- Entomology—*see also* Insects.  
economic, contributions on, 64, 501.  
extension, chalk talks in, 358.  
Extension Service of Kansas, organization, 358.  
teaching to adults, 358.
- Enzymes—  
activity, effect of salts on, 245.  
studies, U.S.D.A. 579.
- Epamerobaphis* in Utah with new species *utahensis*, description, 218.
- Eperythrozoon coccoides*, natural transmission, insect vector, 830.
- Ephestia*—  
*cautella*, *see* Almond moth.  
*elutella*, *see* Tobacco moth.

Fatty acids of goat milk fat, 580.

## Feces—

bovine, coliform bacteria in, 385.

bovine, examination for *Brucella abortus*, 849.

iodine determination in, 150.

Feeding experiments, see Cows, Pigs, etc.

## Feeding stuffs—

analyses, Ky. 375; N.Y.State 4.

byproducts, evaluation, Calif. 834.

Canadian, digestibility, 670.

chemical studies, Tex. 517.

distribution of filtrate factor of vitamin B complex in, 81.

for poultry rations, relative vitamin G in, [N.Y.]Cornell 835.

grinding, new buhr type mill for, 861.

## Feeding stuffs—Continued.

inspection and analyses, Mass. 837; Me. 518; N.H. 519; R.I. 83; Tex. 837; Vt. 670.

iodine in, relation to endemic goiter, 374.

mineral deficiencies in, Mont. 669.

processing on Nebraska farms, Nebr. 114.

production-consumption balance, Mich. 709.

shipments into the State, Del. 707.

Felljoa fungus diseases, 817.

*Feltia ducens*, ecology and control, Tenn. 663.

Fence posts of tamarisk, creosoting, Ariz. 109.

Fencing with electricity, 257.

Fenugreek as soil-building crop, Calif. 780.

Fermentation, Semichon process, 299.

Fern prothallia, reproduction in, effect of

light and other factors, [N.Y.]Cornell 764.

Ferns, effect of X-rays on growth and metabolic processes in, [N.Y.]Cornell 764.

Ferric silicates, composition and ionic exchange, 161.

## Fertilizer—

experiments—see also special crops.

Mo. 589.

mixtures, calculating, N.C. 310.

## Fertilizers—

analyses, Me. 600; S.C. 165; Tex. 600.

comparison, N.Y.State 626.

data on, Vt. 310.

distribution machinery and practices, U.S.D.A. 542.

effect on loss of microscopic organisms from soils, [N.Y.]Cornell 752.

for snap beans, machine placement, U.S.D.A. 257.

granulated, merits, N.Y.State 762.

inspection, Mass. 455; R.I. 762.

inspection and analyses, Conn.[New Haven] 599; Ind. 455.

manufacture and use, progress in, 178.

mixed, technology, U.S.D.A. 589.

nitrogenous, see Nitrogenous.

non-acid forming, basicity of materials used, 759.

placement, Mich. 589.

placement research, new developments, 860.

profit from, treatise, 762.

residual effect on subsequent crop of peas, N.Y.State 626.

studies, Tenn. 7.

value to crops, Mich. 589.

## Fescue—

meadow, feeding value of hay from, 669.

seed, Chewing's, decline in viability, 737.

seed, viability, N.Y.State 624.

Fetuses, near term dead, retention, reaction of rat mother to, 320.

Fibroma virus of rabbits, transmission, 109.

*Fidia vitticida*, see Grape rootworm.

## Field experiments—

preliminary studies of artificial plats for, Tex. 446.

technic in, 26.

  - fertilizer experiments, 799.
  - flowers, chemical composition, 799.
  - Marsh, use of water by, Ariz. 482.
  - maturity, effect of culture, fertilizers, sprays, *etc.*, Tex. 476.
  - maturity studies in Salt River Valley, 482.
  - orchards, bearing, deterioration, Tex. 476.
  - orchards, heating, Tex. 476.
  - storage, Ariz. 38; Tex. 476.
- Grapes—
  - American, growth and fruiting, effect of rootstock, Ark. 625.
  - breeding, N.Y.State 629; U.S.D.A. 625.
  - breeding and culture, Tenn. 38.
  - bunch, in north Georgia, Ga. 632.
  - chromosomal structure in, N.Y.State 629.
  - Clairette variety, fruit drop in, 187.
  - Concord, color development, relation to number of leaves per cane, 481.
  - culture, Tex. 476.
  - diseases, pocket atlas of, 815.
  - export, wastage, 647.
  - fertilization, pruning, and breeding, N.Y.State 629.
  - fertilizer treatments, 481.
  - fertilizers for, twenty-five year test, N.Y.State 42.
  - growth, effect of seed development, 480.
  - inbreeding and heterosis in, 23.
  - irrigation requirements, Calif. 790.
  - large-berried strains of Sultanina, producing bud mutation, 480.
  - liming, value, 481.
  - mold control during transit and storage, 352.
  - muscadine—
    - breeding and propagation, Ga. 381.
    - growing in South, 480.
    - jelly and wine from, Ga. 297.
    - pollination and new varieties, 480.
  - mutations of vinifera varieties, 480.
  - nutritional requirements, Mo. 625.
  - rootstocks for, Tex. 476.

Grapes—Continued.

- soil moisture studies, 792.
- uneven ripening, Ark. 625.
- varieties, Colo. 476.
- varieties for high-quality wines, Calif. 740.

Grapevines—

- bleeding in, nature, Calif. 790.
- new disease, Calif. 804.

*Graphiola phoenix* on date palms, control, Ariz. 46.

*Graphium ulmi*, see *Oeratosomella ulmi*.

*Grapholitha molesta*, see Fruit moth, oriental.

Grass—

- and red clover mixture harvested at different stages, nutritive value, 836.
- artificially dried, nutritive value and effect on milk quality, 237.
- dried, vitamin B<sub>1</sub> in, 516.
- drying, process in use in England, 703.
- extracts, minerals in, modified analytical methods for study, 378.
- farming in the South for profit and soil conservation, 781.
- green and cured, digestibility, determination, 517.
- in soil erosion control, U.S.D.A. 323.
- juice, growth stimulating properties, 84.
- meadows, irrigation methods, Colo. 468.
- mixture, good, determination, Mont. 618.
- quantity consumed by grazing cows, 236.
- seed, harvesting, 258.
- seed production, gall midges affecting in mid-Wales, 178.
- seedling anatomy, first internode of *Avena* and *Triticum*, 608.
- silage and possibilities, 781.
- silage, methods of making, 526.

Grasses—see also Grassland, Lawns, Pastures, etc.

- at different stages of growth, iodine in, 374.
- effects of heat and drought in Great Plains, U.S.D.A. 617.
- English, selected for leafiness, strain tests, Mo. 618.
- forage, adaptation studies, Hawaii, 780.
- genetic impurity, 20.
- of New Zealand, description and keys, 179.
- of West Indies, manual, U.S.D.A. 781.
- pasture, and mixed concentrates, composition, comparison, 517.
- pasture, composition and vitamin content, effect of stage of maturity, Ohio 371.
- pasture, effect of meteorological factors, 445.
- pasture, grasshopper injury to inflorescence, 68.
- pure cultivated, feeding value of hay from, 669.
- range, composition, seasonal changes in, Ariz. 80.

Grasses—Continued.

- range, mineral deficiencies, Ariz. 80.
- response to mineral v. organic nitrogen, Mich. 589.
- susceptibility to *Cercospora herpotrichoides*, 807.
- variety tests, Tex. 468.

Grasshopper—

- differential, notes, Ill. 827.
- differential, parasite of, 68.
- range, biology, Ariz. 65.
- red-legged, control, Ill. 827.
- red-legged, parasite of, 68.

Grasshoppers—

- and agricultural development in North Dakota, 362.
- control by farm operators, 358.
- egg-deposition survey of Utah, 214.
- in New South Wales, parasitic enemies, 506.
- injurious, in U. S. S. R., 1925-1933, 217.
- injurious to inflorescence of grasses, 68.
- migratory, control, 216.
- notes, U.S.D.A. 654.
- of Arizona, food plants, 68.

Grassland—see also Grasses and Pastures. products, composition, digestibility, and nutritive value, 88.

Grazing—see also Range.

- districts in Montana, purpose and organization, Mont. 412.
- methods, Colo. 468.
- systems, comparison, Mo. 618.

Great Lakes-Saint Lawrence waterway project, U.S.D.A. 865.

Great Plains, environment and life in, climatic cycle as factor, 301.

Green bug development, relation to temperature, 218.

Green manure—

- crops, winter, value, N.J. 324.
- experiment on Norfolk sand, 807.

Greenhouse—

- plants and grasses, mollusk pest of, 227.
- thrips, notes, 69.

Greenhouses, unit heaters in, 701.

Git in all-mash chick ration, Mo. 668.

Ground hogs, plague infection in fleas and lice taken from, 652.

Grouse—

- ruffed, fluctuations in numbers, 500.
- ruffed, in Wisconsin, 211.
- ruffed, research in New York State, 821.
- sharp-tailed and pinnated, winter food in Wisconsin, 821.

Growth—

- and reproduction in rats, effect of raw and sterilized milk, 717.
- effect of dextrin and sucrose, 187.
- hormones in plants, 600, 601.
- rate, relation to basal metabolism, 720.
- studies, 182.
- substance, determination methods, accuracy, 600.

## Growth—Continued.

substances, effect on fungi, W.Va. 804.  
substances or hormones, relation to horticultural practice, 788.

*Gryllus domesticus*, see Cricket, house.

Guar as soil-building crop, Calif. 780.

Guinea pig, polydactylous monster, development, 19.

## Guinea pigs—

inbreeding experiments, U.S.D.A. 612.

nutritional requirements, Mo. 668.

raising, U.S.D.A. 356.

spotted pattern of, genetics, 775.

*Gymnosporangium*—

*clavipes*, hosts, life history, and control, 47.

galls, morphological aspects, 806.

*juniperi-virginianae*, viable basidiospores, dispersal, 47.

Gynandromorph of *Paratettix texanus*, morphology and cytology, 19.

Gypsum, use in fertilizers for cotton, Ga. 323.

## Gypsy moth—

control, 64, 826.

in Eurasia, Africa, and New England, 219.

in Petersham, Mass., 659.

notes, U.S.D.A. 654.

*Haemaphysalis thyrideropterygis*, notes, 370.

*Habrolepis roulei* n.sp., description, 513.

*Haemonema* parasites of Army animals in United States and in Philippines, 540.

*Haematobia irritans*, see Horn fly.

*Haemonchus*—

*contortus* in lambs of southwest Britain, 251.

*contortus* infestation of grazing sheep, effect of salting of pasture, 251.

infection of calves, 250.

*Haemoproteus columbae* of pigeons, 398.

Hair fibers, cross sections and length and crimp, development of apparatus for study, U.S.D.A. 667.

Hair, woolly, condition in swine, 23.

Hallbut-liver oil, studies, U.S.D.A. 579.

Halowax as ovicide for codling moth and oriental fruit moth, 363.

Hams, work of Food Investigation Board of Great Britain, 877.

*Haplothrips victoriensis*, notes, 69.

Harellip in mice, 464.

*Harmolita*—

genus, second revision, U.S.D.A. 369.

*tritici*, see Wheat jointworm.

*Harmostomum commutatum* in partridges, 252.

Hawaii, a pageant of the soil, 259.

Hawaii Station, report, 894.

Hawks, marsh, food habits in glaciated prairie region, 822.

## Hay—

acresages, yields, and total production, U.S.D.A. 712.

artificially dried, feeding value, Vt. 235.

composition and vitamin content, effect of stage of maturity, Ohio 371.

cost of production, N.C. 119.

## Hay—Continued.

crops, fertilizing, 781; N.H. 469.

drying, process in use in England, 703.

hoists, electric, home-made, 114.

leguminous, use of stem crusher in curing, Mich., 699.

of Manitoba, mineral content, 227.

plane of nutrition and digestibility, 670.

plants, growth and composition, effect of

reseeding and fertilization, Vt. 178.

production-consumption balance, Mich. 709.

spontaneous ignition and dust explosion, U.S.D.A. 704.

stacked, volumes and weights, Mont. 704.

supplementary value for brood sows, Ark. 376.

tonnage, determination in long stacks and round stacks, Nev. 406.

yields, effects of summer soil-conserving crops on, U.S.D.A. 323.

## Health—

after middle life, effect of protein level, [N.Y.] Cornell 879.

inspection, newer ideas in, 561.

national, and nutrition, 880.

public, relation to refrigeration of foods, 128.

services in rural areas, Ark. 713.

Heart rate in vitamin B<sub>1</sub> and vitamin C deficiency, 566.

## Heating—

home, oil burners for, U.S.D.A. 550.

home, practical information, 732.

of greenhouses, unit heaters in, 701.

systems for houses, design, 141.

## Hedgehog—

female, reproductive cycle, 210.

male, reproductive organs, seasonal variation in, 210.

Hegari fodder and cottonseed meal ration, physiological effect on dairy cows, 525.

## Heifers—

beef, phosphorus deficiency metabolism and food utilization, 671.

beef, value of pastures with and without cottonseed meal, Ga. 370.

blood calcium and phosphorus during first gestation and lactation, effect of phosphorus intake, 526, 681.

dairy, delayed conception and sterility in, Ky. 97.

dairy, pasture tests with, Ga. 383.

feeding experiments, La. 529.

phosphorus requirements during gestation and lactation, W.Va. 841.

pregnant, effect of fluorine, 373.

pregnant, inorganic phosphorus in blood, 372.

raising, amounts of feed and labor used in, W.Va. 530.

wintering on high or low plane of nutrition, Mont. 668.

## Heliothis—

*obsoleta*, see Bollworm and Corn earworm.

*virescens*, see Tobacco budworm.

**Heliothrips—***fasciatus*, see Bean thrips.*haemorrhoidalis*, see Greenhouse thrips.

Helminth aneurisms of equines, etiology, 852.

**Helminthosporium—***gossypii* on cotton in Peru, 642.*sativum* on barley seed, effect, 842.*setariae* on millet, U.S.D.A. 634.

sp. causing date blight, Ariz. 46.

spp. on barley seed, N.Y.State 636.

Helminths in animals, diagnosis, Mich. 689.

Helminths in Baltimore house rats, 212.

Helminths in British partridges, 252.

Helminths in domestic animals in Brazil, synopsis, 848.

*Helopeltis bergrothi*, studies, 828.*Hemianaphothrips concinnus*, notes, 69.*Hemileuca oliviae*, see Range caterpillar.**Hemoglobin—**

deficiency, mechanism, 578.

formation, availability of copper as iron supplement, 723.

values in normal adults, 723.

**Hemophilus—***gallinarum*, studies, 697.*influenzae suis*, notes, 395.**Hemorrhagic—**

disease, dietary, in chicks, 677.

septicemia, see Septicemia.

Hemp, sunn, root systems, 326.

**Hens—**

artificial insemination with mixed semen from several cockerels on alternate days, U.S.D.A. 612.

laying—see also Egg production.

activity, effect of pure vegetable protein, 523.

and breeding, batteries for, Hawaii, 835.

artificial illumination for, value, Hawaii 835.

blood calcium, 675.

effect of forms of iodine, 374.

effect of high protein mash for, W.Va. 836.

effect of iodine feeding, 378.

effect of vitamin D sources, 283.

oystershell v. mussel shell for, 88.

protein requirements, [N.Y.]Cornell 835; Wash. 232.

skim milk or water preference, 377.

vitamin D requirements, Pa. 284.

yield and cost of production, Mich. 708.

Hepatitis, infectious necrotic, control, 537.

**Heredity of—**

acquired characters and provisional hypothesis of pangenesis, 175.

bean powdery mildew resistance, Calif. 641.

carotene in carrots, 772.

characters affecting egg quality, 465.

color, see Color inheritance.

complementary dwarfing factors in, 22.

cryptorchidism in swine, 177.

egg production, persistency, 612.

fecundity in swine, 177.

glume length in ragi, 21.

**Heredity of—Continued.**

grain shattering in rice, 610.

green flowered variation in cucumbers, 772.

growth rate in Barred Plymouth Rock poultry, 464.

hernia, umbilical, in rats, 317.

horns in Galloway-Holstein cattle crosses, 773.

lop-eared character in rabbits, 317.

polled character in fine wool sheep, Tex. 463.

pungency in chilies, 174.

rate of laying in fowls, 177.

red pericarp color in rice, 610.

ridgling character in goats, Tex. 463.

screw tail in cattle, 317.

seed size and botanical characters in, 174.

semi-hairlessness in cattle, 176.

shank color in fowls, 675.

size in mice, 463, 464.

skeletal dimensions in fowls, 24.

suckering and tip layering in purple raspberries, 631.

white facial markings in Arabian horses, 611.

wilt resistance in watermelon, 208.

yellow anthers in Italian millet, 20.

Heredity principles, textbook, 771.

Hernia, umbilical, inheritance in rats, 317.

**Hessian fly—**

control, Mo. 364.

*Hordeum* grasses as hosts, 76.

infestation of wheat, survey, Ohio 214.

notes, U.S.D.A. 654.

pupal period, 76.

resistant wheat varieties, Mo. 655.

**Heterakis—***gallinae*, notes, P.R. 856.*spumosa* in house rats, 213.**Heterodera—***marioni*, see Root knot nematode.*radicicola*, see Nematodes.**Heterodera schachtii—**

action of hypochlorite solutions, 354.

host plants, 57.

infected soil, control of potato-sickness on, 57.

infected soil, effect of calcium cyanamide and other fertilizers, 58.

new host plants, 499.

on tomatoes in Great Britain, 814.

thermal death-point, 57.

Heteronera, feeding habits, 219.

Heterophyceae and Chlorophyceae of Oklahoma, 12.

*Hibiscus cannabinus* seeds, injuries due to bacteriosis in, 62.

Hickory shuckworm, control, U.S.D.A. 654.

Hides and skins, preservatives for, U.S.D.A. 579.

Highways, see Roads.

Hill grazings, improvement, 178.

*Hippelates*, see Eye gnats.*Hippodamia convergens*, see Ladybeetle, convergent.

*Histomonas meleagridis*, notes, 853.

Hog cholera—

bacillus, relation to human disease, 247.

control, U.S.D.A. 688.

haemacytological changes in, 244.

prevention with crystal violet vaccine, 589.

resistance of Berkjala breed of swine, 589.

virus, serial passage in guinea pig, effect, 589.

Hogs, *see* Pigs and Swine.

Home economics, extension work, U.S.D.A. 269.

Home industries, products, marketing, Ark. 713.

Homeosis in axial skeleton of rabbit, inheritance, 19.

*Homoeonoma ellectum*, notes, 66.

Honey—

adulteration with invert sugar, detection, 154.

combs, chlorine treatment, laboratory and field tests, 369.

cost of production, Calif. 863.

plants, relation to insects, Tex. 502.

potential alkalinity, 419.

production, relation to distribution of California buckeye, U.S.D.A. 655.

studies, U.S.D.A. 579.

Hop—

disease survey in New York State, U.S.D.A. 193.

diseases, studies, 636, 814; N.Y.State 202.

downy mildew in Pacific States, U.S.D.A. 803.

downy mildew, notes, Calif. 804; N.Y. State 636.

mildew resistant varieties, breeding, U.S.D.A. 625.

roots, string of pearls disease, 53.

*Hoplothrips*—

*flavus* n.sp., description, 218.

*quercus* n.sp., description, 218.

Hops—

composition, relation to maturity and environment, U.S.D.A. 625.

curing, 702.

drying, 702.

infectious sterility, 58.

variety and cultural experiments, N.Y. State 629.

Hormones—

chemistry of, 742.

gonadotropic—

and oestrogenic, extraction from blood, improved technic, 322.

effect on chicks, 614.

from blood serum of pregnant mares, biological properties, 467.

inhibitory effects of hypophysis, 467.

gonad-stimulating—

concentration in blood serum, 779.

role in reproduction, 611.

male and female, injection into chick embryos, sex modification, 778.

Hormones—Continued.

root-forming, transport in woody cuttings, 334.

use in combating sterility in dairy cattle, [N.Y.]Cornell 777.

Horn flies, notes, U.S.D.A. 654.

Horn fly, parasites of, 511.

Horse—

disease caused by ingestion of moldy corn, 694.

fossil, remains from upper Pliocene of Idaho, 775.

new lethal factor in, 611.

Horseflies, biology, Ark. 655.

Horseflies of Arkansas, Ark. 221.

Horseshoe brittle root in Illinois, U.S.D.A. 839.

Horses—

Arabian, white facial markings in, inheritance, 611.

at rest, consumption and elimination of water affecting nitrogen excretion in urine, 838.

breeding, feeding, and management studies, U.S.D.A. 667.

breeding problems, Calif. 834.

breeding, status and anticipated needs of research, U.S.D.A. 24.

malignant neoplasms of the eye in, 104.

man and motor, comparison between efficiency, Mo. 370.

parasites of, Hawaii 820; U.S.D.A. 689.

work, protein requirements, [N.Y.]Cornell 835.

work, rations for, Mo. 668.

*Hospitalitermes hospitalis*, biological study, 658.

House wiring and electricity, handbook, 117.

Housefly, parasites of, 511.

Housekeeping, textbook, 575.

Houses—

prefabricated, use of plywood in, 253, 254.

tenement, securing against settlement by reducing soil pressure and draining, 401.

Human ecology, geographic approach to study, 125.

Humans, height, weight, and age tables for homogeneous groups, 561.

Humic acid preparation, behavior toward bromination treatment, 452.

Humidity, atmospheric, control in culture studies, 766.

Hyacinth-bean as soil-building crop, Calif. 780.

*Hyalella knickerbockeri*, intermediate host of duck parasite, 398.

*Hyalopterus*—

*arundinis*, *see* Plum aphid, mealy.

*atripholis*, vector of bean mosaic virus, 344, 659.

Hybrid vigor, commercialization in tomatoes, 476.

Hybridization—*see also* Plant breeding and specific animals and plants.

- Leeftmansia bicolor*, notes, 218.
- Legume—  
 bacteria, need of improved strains, N.Y.State 894.
- Legume—Continued.  
 hays for wintering native calves, Mo. 668.  
 inoculants, inspection methods, 830.  
 root nodules, excretion of amino acids from, 315.
- Legumes—see also Green manure and Alfalfa, Clover, etc.  
 adaptation studies, Hawaii 780.  
 and corn, interplanting, Ark. 617.  
 cross-inoculation, [N.Y.]Cornell 781.  
 drilling fine limestone for, Mo. 11.  
 inoculation—see also Nodule bacteria.  
   studies, Tex. 469.  
 percentage of nitrogen in and effect on nitrogen economy of soil, 14.  
 root-hair growth, stimulation by sterile secretions of nodule bacteria, 602.  
 soluble carbohydrates in, relation to silage production, [N.Y.]Cornell 781.  
 tropical, root nodule bacteria of, 770.  
 variety tests, Tex. 468.  
 winter, for hay, rates of seeding, Ga. 824.
- Leis dimidiata*, introduction into citrus groves, 665.
- Lemon—  
 flowers, chemical composition, 799.  
 fruits, apparent growth rate as index of moisture supply of tree, 799.
- Lemons—  
 irrigation, Calif. 790; U.S.D.A. 625.  
 pooling operations of Santa Paula Citrus Fruit Association, Calif. 557.  
 size, effect of decreasing soil moisture supply, 799.
- Lepidoptera of Pyrenees, catalog, 831.
- Lepidopterous larvae, food plants, 656.
- Lepidosaphes*—  
*beckii*, see Purple scale.  
*ulmi*, see Oystershell scale.
- Leptinotarsa decemlineata*, see Potato beetle, Colorado.
- Leptobyrsa rhododendri*, biology, 362.
- Leptocoris trivittatus* control by sulfonated higher alcohol spray, 501.
- Leptospirosis of dogs, 243.
- Leptothrips mali*, notes, S.C. 217.
- Lepturini of Oregon, annotated list, 828.
- Lespedeza—  
 annual, cutting and fertilizer tests, Tenn. 29.  
 fertilizer experiments, Ky. 29.  
 hay from different varieties and localities, composition, Ky. 29.  
 Korean, hay, composition, digestibility, and milk-producing value, Va. 383.  
 new early, adaptation, U.S.D.A. 617.  
 variety tests, Ky. 29; Tenn. 29; Tex. 468.
- Lespedeza sericea*—  
 and No. 1 Korean hay, feeding value, Ky. 81.  
 culture experiments, Tenn. 29.  
 hay, composition, digestibility, and milk-producing value, Va. 383.

***Lespedeza sericea*—Continued.**

- seed treatments and seeding on winter grasses, Tenn. 29.
- value for different purposes, U.S.D.A. 617.

**Lettuce—**

- bacterial slimy rot and fungus diseases, Ariz. 46.
- beds under irrigation, movement of salts in, 628.
- boron requirements, 761.
- Botrytis* rot, control, [N.Y.]Cornell 804.
- breeding, Hawaii 790; U.S.D.A. 625.
- disease caused by *Sclerotinia* spp., Ariz. 202.
- fertilizers for, Ariz. 38.
- headed and nonheading forms, relative value as mineral sources, U.S.D.A. 715.
- improvement, [N.Y.]Cornell 791; U.S.D.A. 617.
- loopers, notes, U.S.D.A. 654.
- red-leg disease, antagonism in fungi as control measure, 492.
- seed, germination in laboratory and in field, 787.
- spotted wilt disease, transmission by thrips, 641.
- tipburn-resistant, development, Colo. 476.
- yellows and other virus diseases, [N.Y.] Cornell 804.

**Leucocytozoa of fowls, 398.*****Leucocytozoon donasae* from ruffed grouse, 500.*****Leucoptera* spp., parasites of, 508.****Leucosis—**

- fowl, transmissibility, 542.
- of fowls, Mo. 689.
- of fowls, blood pH and filtrability of agent, 107.

**Leukemia—**

- in mice, genetic and extrinsic factors in inheritance, 776.
- of fowls, culture in vitro of causative agent, 251.

**Levulose and arabinose, studies, U.S.D.A. 579.****Library service in rural communities, availability, use, and needs, Mo. 713.****Lice from marmots, plague infection in, 652.****Lice, injurious to elms, Colo. 218.****Light—see also Sunlight.**

- effect on growth, flowering, rooting, and budding of plants, 765.
- effect on ovulation in fowls, 379.
- effect on reactivity of plants to growth substance, 313.
- effect on unweighted and tin weighted silk, 891.
- in woods, intensity and color, measurement, 606.
- monochromatic, reactions of plants to, 166.
- quartz mercury arc, description, 311.
- traps for Asiatic beetle, recent developments in, 664.

**Light—Continued.**

- traps for Asiatic garden beetle, construction and use, U.S.D.A. 501.
- traps for control of insects, N.Y.State 216.
- traps, notes, Calif. 824.
- traps, role in control of mushroom springtail, 67.
- variation, effect on white pine seedlings, 802.

**Lignin—**

- decomposition by micro-organisms, 163.
- in Douglas fir, 746.
- preparation, behavior toward bromination treatment, 452.
- quantitative estimation, 153.
- studies, U.S.D.A. 579.

**Lilies, virus diseases, 194.****Lilium—**

- henryi*, development of embryo sac, 18.
- spp., development of male gametes, 611.
- Lily bulb thrips, life history, 506.
- Lily diseases, [N.Y.]Cornell 804.

**Lima beans, see Beans, Lima.****Lime—see also Calcium and Liming.**

- effect on availability of potash, Del. 589.
- for field and forage crops, W.Va. 762.
- high-calcium and dolomitic hydrated, comparison for sprays, Mich. 189.
- products, inspection, Mass. 762.
- spray, effect on foliage of citrus, Ariz. 46.
- use, Ark. 617.

**value in two-year rotation on Sand Mountain, Ala. 310.****Limes, new disease, causes and prevention, 317.****Limestone, dolomitic, as filler, W.Va. 762.****Lime-sulfur—**

- and copper sulfate for *Exoascus* infection of peach trees, comparison, 647.
- and iron sulfate mixture as spray, 640.
- for apple scab, evaluation of different applications, N.Y.State 636.
- home-made liquid, manufacture, Ohio 40.

**Liming—**

- materials, calcium and magnesium oxide contents, N.Y.State 4.
- soils, calcium carbonate equilibration method, 104.
- soils, effect on sorption and distribution of phosphorus in aqueous and soil colloidal systems, 309.

**Limnea—**

- tenera euphratica*, host of *Schistosoma turkestanicum*, 692.
- truncatula* in southwestern Norway, 658.
- Limothrips cerealeum* on cotton, S.C. 217.
- Lingualula serrata* in Australia, 99.

**Linkage—**

- group in pigeon, three-factor autosomal, 19.
- in corn, virescent seedling with japonica, 19.
- maps, revised, of chromosomes 5 and 9 in corn, 19.

## Linkage—Continued.

- of pink-eye and albinism in deer mice, 818.
- relations in beets, 19.
- relations of crest, dominant white, and frizzling in fowls, 318.
- studies in rats, 318.
- studies with wavy mice, 776.

## Linseed—

- meal v. soybean oil meal for dairy cattle, 843.
- oil, competition with other drying oils, Calif. 262.

*Liothrips*—

- oleae*, biological study, 218.
- sp., on cotton, S.C. 217.
- vaneeckei*, life history, 506.

## Liquids, precision pycnometer for, 746.

*Listroderes obliquus*, see Vegetable weevil.*Listrophorus validus* of British muskrat, 652.

## Litchi—

- introduction into Hawaii, Hawaii 790.
- selective breeding and propagation, Hawaii 790.

## Liver—

- copper determination in, 295.
- fatty, action of choline in prevention and cure, 571.
- fatty, cholesterol, effect of caseinogen, 571.
- fatty, dietary production, relation to protein, 128.
- fatty, dietary production, effect of cystine, 571.
- fatty, prevention with caseinogen, 572.
- fatty, production, role of various fats in, 572.
- flake control, 537.
- flake in sheep, effect of continuous administration of carbon tetrachloride, 538.
- flake of cattle, control, Hawaii 820.
- flake snail, ecological investigations, 653.
- of infants and fetuses, copper in, 130.
- parenchyma, Leuchtstoff X in paraplasmaic fat globules, nature, 276.
- preparations, iron and copper contents, 421.
- vitamin A variations in, 276.

## Livers, hard yellow, in sheep and cattle, Tex. 533.

## Livestock—see also Animals, Mammals, Cattle, Sheep, etc.

- adjustments in State, recommendations for, Mich. 708.
- auctions, farmers' attitudes toward, 263, Ohio 259.
- breeding, status and needs of future, U.S.D.A. 23.
- breeding, unusual possibilities in, U.S.D.A. 23.
- deficiency disorders resulting from emergency rations, 375.
- diseases, see Animal diseases and specific diseases.
- losses, studies, Ariz. 97.

## Livestock—Continued.

- marketing, changes in, 408.
- marketing methods in Denmark, Great Britain, and Canada, Iowa 870.
- numbers, prices, and profits in Montana, Mont. 708.
- poisoning, see Plants, poisonous, and specific plants.
- price situation of Dayton, Ohio, analysis, 263.
- problems, economic aspects, Mont. 708.
- production and cropping systems, interrelations on Iowa farms, 551.
- range, cooperative marketing, 556.
- research, Mont. 733.
- statistical trends, Del. 707.
- structures, electrical ventilation systems for, Mich. 705.

## Living, standards of, see Standards.

*Lioophaga diatraeae*—

- notes, 658.
- parasites of sugarcane borer, rearing and release, 824.

## Lizards—

- food habits in Skull Valley, Utah, 212.
- of United States and Canada, key, 212.
- Troutcreek, insect food of, 214.

## Locoweed poisoning, Tex. 533.

## Locust—

- bark, proteins in, U.S.D.A. 579.
- black, seedling wilt, 353.
- conference held at Pretoria, proceedings, 505.
- desert, annual cycle, migrations and periodicity in Persia, 216.
- desert, life history and habits, 216.
- desert, studies, 658.
- lesser migratory, Ill. 827.
- oriental migratory, 505.
- outbreaks in Philippines and sunspot cycles, 505.

*Locusta migratoria*—

- in U. S. S. R., 217.
- manilensis*, oriental migratory, 505.
- migratorioides*, development, relation to humidity and temperature, 217.
- migratorioides*, locomotor activity in, 505.

## Locusts, African, development, relation to humidity and temperature, 217.

## Loganberries, effect of irrigation, Oreg. 630.

*Lomachaeta* new genus, erection, 369.

## Louisiana Station, notes, 734.

## Louisiana University, notes, 734.

*Louricla ovivora* n.g. and n.sp., description, 80.*Lowostege sticticalis*, see Webworm, beet.Lubber grasshopper and *Aulicus terrestris*, relation, 665.

## Lubricants, laboratory testing, 112.

*Lucilia*—

- larvae, specific taxonomic characters, 221.
- sericata*, effect of environment, 664.
- sericata* larvae, therapeutic action, 246.

- Lumber—see also Timber and Wood.  
construction, recent developments applicable to farm building, 253.  
injury by *Hadrobregmus carinatus*, 357.  
selective breeding and propagation, Hawaii 790.
- Lungs, calf, nutritive value of protein in, 371.
- Lungworms—  
control with oil extract of pyrethrum, W.Va. 849.  
in white-tailed deer, 398.  
of swine, control, U.S.D.A. 104.
- Lupine—  
basal disease and root rot, 491.  
disease, virus, 55.  
meal, digestibility by hens, 230.  
meal, suitability for chicken rearing, 230.
- Lycet powder-post beetles, food relations, 368.
- Lygus pratensis*, see Tarnished plant bug.
- Lygus vosseleri*, studies, 828.
- Lymphangitis in cattle, immunization, Nev. 243.
- Lymphomatosis, studies, 854.
- Lysimeter experiments, tank records, [N.Y.] Cornell 753.
- Lysine, bovine maintenance requirement for, 236.
- Lysozyme—  
action, mechanism, 744.  
purification and properties, 581.
- Macadamia nuts—  
giant, from Queensland, Australia, Hawaii Sugar Planters' 632.  
grading, curing, and cracking, Hawaii 790.  
improvement by selection and top-working, Hawaii 790.  
introduction into Hawaii, Hawaii 790.  
propagation, Hawaii 790.
- Machinery, see Agricultural machinery.
- Machines, massive foundation under, theory of vibration, 401.
- Macrocentrus ancyliovorus*, notes, N.Y.State 656.
- Macronoctua onusta*, see Iris borer.
- Macropsis trimaculata*, incubation period of virus of peach yellows in, 70.
- Macrorespirometer, description, 18.
- Macrosiphum—  
ambrosiae, vector of bean-mosaic virus, 344, 659.  
breviscriptum n.sp., description, 363.
- Macrosporium sarcinacforme on tomatoes, temperature studies, U.S.D.A. 59.
- Macrotermes gilvus, biological study, 658.
- Maggot therapy—  
progress in United States and Canada, 246.  
rapid method of removing necrotic tissues, 247.  
value of urea in, 690.  
work with allantoin, 690.
- Magiocolada septendecim, see Cicada, periodical.
- Magnesia in fertilizers, effect on tobacco, Conn.[New Haven] 166.
- Magnesium—  
carbonate as supplement to whole milk calf ration, 526.  
in blood and in plant tissue, microdetermination, 872.  
low blood, in dairy calves, effect, 526.  
metabolism and significant disturbances, 274.  
needs of preschool children, 883.  
of white rats, variations in, 274.  
oxide as supplement to whole milk calf ration, 526.  
phosphorus, and vitamin D in ration, relation, Mich. 679.  
use in fertilizers for cotton, Ga. 323.
- Magpies, control, U.S.D.A. 356.
- Malachite green, eventual application in phytotherapy, 50.
- Malacosoma—  
americana, see Tent caterpillar, eastern.  
disstris, see Tent caterpillar, forest.
- Malaria—see also Mosquitoes and Anopheles.  
possibility of outbreaks in New Jersey, N.J. 510.
- Male hormone concentrates, effect on accessory reproductive organs of rodents, 780.
- Mallein, use, U.S.D.A. 688.
- Mallophaga of mammals of South America, 504.
- Malpighamoeba locustae n.sp., description, 68.
- Malta fever, see Undulant fever.
- Malting, experimental, design and operating of laboratory equipment, 746.
- Malvaceae, chromosome numbers in, 173.
- Mammals—see also Animals and specific kinds.  
and life zones of Oregon, U.S.D.A. 357.  
multiparous, birth weight and litter size, relation, 25.  
reproductive processes, 210.
- Mammary gland—  
development and function, effect of hypophysectomy, 175.  
development and lactation, physiology of, [N.Y.]Cornell 778.  
development in hypophysectomized rats, 320.  
of hypophysectomized guinea pig, effect of estrogenic hormones, 320.  
site of synthesis of fat in, 526.  
slices, synthesis of lactose by, 843.
- Mammitis, see Mastitis.
- Manganese—  
deficiency affecting beans, Fla. 344.  
deficiency, relation to marsh spot in peas, 202.  
in New Jersey soils, 761.  
relation to plant growth, 459, 761; [N.Y.]Cornell 764.
- Mango—  
flowers and fruits, scale insects on, 71.  
fly, autecology, 833.  
insect pests in Ceylon, 353.

- Mangoes**—  
composition and nutritive value, 717.  
variety tests and propagation, Hawaii 790.
- Manure**—  
artificial, production on the farm, Mo. 809.  
conservation by superphosphate, Vt. 158.  
natural fauna used in preparation of mushroom beds, 825.  
value and conservation, N.Y.State 762.
- Maples and oaks**, relative feeding power for soil phosphorus, 802.
- Maps**, climatic, of North America, 444.
- Marasmius rotula***, notes, 636.
- Mare serum**—  
pregnancy, studies, Mo. 613.  
two gonadotropic substances in, 779.
- Mares**—  
brood, type suitable for mule production in South, Ga. 370.  
pregnant, gonad-stimulating hormone in blood and oestrin in urine, 779.
- Margarine**—*see also* Oleomargarine.  
effect on fecal output of Ca in rats, 503
- Marigold** petal spot, Tex. 488.
- Market**—  
gardening, *see* Truck crops.  
reports, U.S.D.A. 124, 414, 557, 870.
- Marketing**—*see also special products*.  
agricultural research projects in North-eastern States, N.H. 556.  
of Australian and New Zealand primary products, treatise, 870.  
regulation by State authority, 556.
- Markets**—  
fruit and vegetable, increase in volume in Louisville, Ky. 117.  
public, situation in south-central New York, [N.Y.] Cornell 863.
- Marmots**, plague infection in fleas and lice taken from, 652.
- Marriage** rate, trend in rural North Carolina, 876.
- Martens**—  
at Fur Animal Experiment Station, U.S.D.A. 500.  
raising in captivity, U.S.D.A. 356.
- Massachusetts** College, notes, 576.
- Massecurites**, shipment, control of boiling, 329
- Mastitis**—  
based on segregation of infected animals, control program, 850.  
chlorine in milk as indication, 386.  
effect on milk yield of cows, 386.  
latent and clinical, detection, 847.  
milk, sequence of bacterial and chemical changes in, 93.  
of ewes due to *Bacterium mastitidis*, 250.  
onset, sequence of change in udder and properties of milk, U.S.D.A. 528.  
staphylococci associated with, 93.  
streptococci causing, detection of shedders, 249.  
streptococci in bulk milk, 386.
- Mastitis**—Continued.  
streptococci in milk, detection, U.S.D.A. 391.  
streptococci, in cattle, 850; Mich. 689; U.S.D.A. 688.  
studies, 103.  
sub-clinical, source of organisms associated with, N.Y.State 692.
- May** beetles, damage caused by in British Isles, 367.
- Mealworm**, yellow, rate of growth and size, relation to temperature and humidity, 308.
- Mealybug**—  
citrus, and ants on grapefruit of Palestine, 215.  
citrus, control, 829.  
grape, vector of stem blight of Texas bluebell, Tex. 62.  
pineapple, control, U.S.D.A. 654.
- Meat**—*see also* Beef, Lamb, Pork, *etc.*  
and meat food products, U.S.D.A. 716.  
canned, processing, Tex. 561.  
canned, quality, effect of time and temperature of processing, U.S.D.A. 716.  
canning, in home, U.S.D.A. 419, 716.  
consumption in rural Tennessee, Tenn. 413.  
fresh beef and carabao, differentiation by hemagglutination, 672.  
purchase and sale by Tennessee farm families, Tenn. 713.  
quality, U.S.D.A. 667.  
tenderness, effect of oven temperature, Tex. 126, 561.  
tenderness, new subjective method of testing, 126.  
work of Food Investigation Board of Great Britain, 877.
- Medicine**, modern, physiology in, treatise, 243.
- Mediterranean** fever, *see* Undulant fever.
- Megauryca langstoni* n.sp., description, 513.
- Melampsora lint.* resistance of flax to, 55.
- Melanconium* sp. on tomatoes, temperature studies, U.S.D.A. 59.
- Melanocallis caryaefoliae*, *see* Pecan aphid, black.
- Melanoplus**—  
*differentialis*, *see* Grasshopper, differential.  
*femur-rubrum*, *see* Grasshopper, red-legged.  
*mexicanus atlantis*, notes, Ill. 827.  
*mexicanus*, parasite of, 68.  
spp., role in cotton wilt transmission, 809.
- Melanospora destruens* sporulation, effect of certain fungi, 173.
- Mellilotus alba* and *M. Officinalis*, differentiating on seed characteristics, 787.
- Meliasus latiferreanus*, notes, 656.
- Melolontha* spp., notes, 824.
- Melon** aphid, transmission of bean mosaic virus by, 659.
- Melonfly**, control, U.S.D.A. 654.
- Melons**, insects affecting, Ind. 503; Mo. 655.

- Melting point apparatus, electrically heated, 746.
- Mendel, L. B., tribute to, Conn.[New Haven] 733.
- Menhaden fish meal, steam dried and flame dried, feeding value, 680.
- Mercury vapor, toxicity to germinating tobacco seeds, 604.
- Merullus lachrymans*, protecting wood against, 650.
- Metabolism—  
   basal, of goats, N.H. 520.  
   basal, of male Chinese in Manchuria, 420.  
   basal, of older women, Ohio 419.  
   basal, relation to adolescent growth, 720  
   basal, relation to dietary intake, 720.  
   diseases of, 573.  
   experiments with beef heifers, 671.  
   nitrogenous, of men in Manchuria, 420.  
   relation to body weight, Mo. 668.
- Metastrongylus* spp., ingestion of inflammatory exudate by, 395.
- Metaxenia—  
   and interspecific pollinations in Phoenix, 800.  
   in apples, 795; N.Y.State 629.
- Meteorological—  
   factors, effects on plant species, 12.  
   forecasts, 334-year cycle for, 443.  
   observations, Ariz. 141; Mass. 588;  
   Mont. 733; N.Y.State 733; U.S.D.A. 156, 301, 588.
- Meteorology—see also Climate, Rainfall, Temperature, Weather, etc.  
   agricultural, in India, 588.  
   agricultural, work of National Meteorological Institute of Poland, 6.  
   manual, revision, 300.  
   papers on, U.S.D.A. 156, 301, 588.
- Metocorus* spp., notes, 79.
- Mice—see also Rodents.  
   association of color and size in, 776.  
   inbred, barrelp character in, 464.  
   interaction of host and normal tissue transplants, 19.  
   mosaic coat color, 818.  
   multiple lethal genes in, 776.  
   size inheritance in, 463, 464.  
   strains and susceptibility to tumors, 19.  
   wavy, linkage studies with, 776.
- Michigan Station quarterly bulletin index, volumes 1-18, 894.

## Milk—Continued.

- raw and sterilized, effect on growth and reproduction in rats, 717.
  - reduction of methylene blue in, factors affecting, 885.
  - samples, composite and fresh, differences, 844.
  - sampling methods for premium payments to grade A dairymen, N.Y.State 91.
  - secretion and composition, effect of environmental temperature, 240.
  - secretion, effect of thyroxin treatment of cows, 531.
  - secretion, factors affecting, 240.
  - skimmed, *see* Skim milk.
  - South African, freezing point, 241.
  - specific gravity, calculation of solids from, factors in, 814.
  - specific heat of fat globules in, [N.Y.] Cornell 841.
  - streptococcus-infected, home pasteurization, Mich. 242.
  - sugar products, studies, U.S.D.A. 579.
  - sulphydryl compounds in, 384.
  - supplies, abnormal municipal, control, N.Y.State 682.
  - supply and utilization in Pennsylvania, Pa. 121.
  - titratable acidity, effect of corn gluten feeding, 90.
  - treatment previous to separation, 527; Vt. 235.
  - variable oxygen absorption as factor in methylene blue reduction test, Vt. 235.
  - vitamin A in, 241, 526.
  - vitamin C in, 527.
  - vitamin C in, effect of breed characteristics and stage of lactation, 384.
  - vitamin C stability in, factors affecting, 241.
  - vitamin D in, effect of cacao shell feeding, 681.
  - vitamin D irradiated and yeast-fed, prophylactic value, 429.
  - vitamin D potency, effect of roughage, 526.
  - yield and composition, effect of injections of sterile solutions into udder, Mo. 679.
  - yield and composition, effect of silage, 237.
  - yield, effect of mastitis and abortion, 386.
  - yield, effect of milking machines, 90.
  - yield, effect of short-time gestations, Mo. 679.
  - yield from separate quarters of the udders, U.S.D.A. 528.
  - yield, relation to progress of lactation, 89.
- Milking—**
- capacity, inheritance, survey of literature, 773.
  - machine, rate of, 240.
  - machine v. hand, 240.
  - machines, effect on milk yield, 90.

## Milkvetch, timber—

- intoxication by, Colo. 532.
  - selective habitat, 533. \*
- Mill, new buhr type for grinding feeding stuffs, 861.**
- Millipedes injury to potato tubers, [N.Y.] Cornell 820.**
- Millet—**
- downy mildew, notes, 809.
  - Helminthosporium setariae* on, U.S.D.A. 634.
  - Indian, types at Government Research Farm, Cawnpore, 472.
  - Italian, yellow anthers in, inheritance, 20.
  - pearl, chlorophyll deficiencies in, 609.
  - pearl, development of tillers on, 472.
- Milo root rot, studies, U.S.D.A. 634.**
- Mimosa pudica, leaf movements, relation to intensity and wave length of radiation, 167.**
- Mineral—**
- composition of rats, 129.
  - deficiencies and nutritional diseases of animals, Colo. 532.
  - losses in vegetables with different methods of cooking, U.S.D.A. 716.
  - metabolism in calves, 843.
  - metabolism, studies in, 371, 373.
  - requirements for commercial chicken and turkey feeds, Tex. 517.
  - salts, chemotropic stimulation of roots by, 768.
  - substances, elimination by plant roots, 815.
- Minerals—**
- for colts, [N.Y.] Cornell 835.
  - in hay of Manitoba, 227.
  - in nutrition, 881.
  - necessary in commercial dairy feeds, Tex. 529.
- Minks—**
- at Fur Animal Experiment Station, U.S.D.A. 500.
  - automatic drinking fountain for, U.S.D.A. 356.
  - food habits in New York, 211.
  - rations for, [N.Y.] Cornell 820.
  - weaned, feeding, U.S.D.A. 356.
- Minnesota Station, notes, 142, 734.**
- Minnesota University, notes, 142, 734.**
- Mint, insects affecting, Ind. 503.**
- Missouri Station, notes, 285, 734.**
- Missouri Station, report, 733.**
- Mite, white mold, on tomato, Ohio 227.**
- Mites—**
- control on mushrooms, 825.
  - moulting, 656.
  - predators and pray, interaction between, 213.
- Mohair—**
- fineness, relation to age of animals, Tex. 516.
  - of Texas, grades and shrinkages, Tex. 516.

- Molasses**—  
 and alfalfa supplements to grain rations for calves, Mo. 668.  
 and grass silage, digestibility, Vt. 235.  
 as supplement to drought corn fodder, Mo. 668.  
 blackstrap, as livestock feed, La. 837.  
 fermentation, butyric acid production from, P.R.Col. 4.  
 in ration of pregnant sows, Mo. 668.  
 pineapple bran, and cane bagasse mixtures, feeding value, Hawaii, 841.  
 pineapple bran, bagasse, and soybean oil meal mixture, feeding value, Hawaii 835.  
 silage, vitamin A in, 526.  
 sugarcane, keeping qualities, 329.  
 use in improving roughage consumption, Hawaii 841.  
 use in poultry ration, Hawaii 835.
- Mold control in grapes during transit and storage, 352.**
- Mold fermentation products from corn sugar, U.S.D.A. 579.**
- Mole crickets, notes, U.S.D.A. 654.**
- Molniss patens* in English stoats and weasels, 252.**
- Monilezia expansa*, notes, 395.**
- Monilia* spp., cultivation, molasses agar as medium, 173.**
- Moniliformis moniliformis* in house rats, 213.**
- Monilopsis adersholdi* and *Rhizoctonia solani*, relation, 491.**
- Monochaetia* sp., relation to fruit rot, 486.**
- Montana Station, report, 733.**
- Mordellistena pustulata*, notes, 65.**
- Mortgage adjustment in New Zealand, 407**
- Mosaic disease, *see* specific host plants.**
- Moscow Laboratory of Climate, notes, 143.**
- Mosquito**—  
 larva, nutritional requirements, 365  
 oil, thiodiphenolamine, a new ingredient, 504.
- Mosquitoes—*see also* *Anopheles* and Malaria.**  
 amount of blood engorged by, 365.  
 anopheline species and subspecies of Malaya, identification, 663.  
 control, and waterfowl, U.S.D.A. 355.  
 control, effects on wildlife, U.S.D.A. 500  
 control, papers on, 832.  
 control with mineral oils, 76.  
 diseases, elimination, Conn.[New Haven] 733.  
 in southeastern Arkansas, 76.  
 notes, U.S.D.A. 654.  
 of Puerto Rico, relation to human welfare, P.R. 221.  
 of Utah, 214.  
 oviposition in, effect of light and darkness, 865.  
 studies, Del. 655.  
 toxicity of certain azo compounds to, 64.
- Moths and catbirds, 857.**
- Motor fuel and vehicle receipts, State disposition, U.S.D.A. 700.**
- Muck**—  
 crops, insect pests, Ind. 503.  
 soils, components, N.Y.State 4.  
 soils, studies, U.S.D.A. 589.
- Mulberry**—  
 diseases, virus, in Kwangtung Province, 195.  
 false mildew, 647.
- Mules**—  
 breeding, U.S.D.A. 24.  
 molasses as feed for, La. 887.
- Mundulea* bark, insecticidal properties, 360.**
- Muriate of potash, effect on *Heterodera schachtii* infected soil, 58.**
- Musca domestica*, *see* Housefly.**
- Muscular dystrophy**—  
 and cod-liver oil in calves, 526.  
 creatine-creatinine excretion and creatine content of muscle in, 882.  
 dietary factors in, 882.
- Mushroom**—  
 beds, new "weed" fungus in, 187.  
 edible, description, N.Y.State 39.  
 pests, notes, U.S.D.A. 654.
- Mushrooms**—  
 cultivated, insect and allied pests, 825.  
 culture, Mich. 476; U.S.D.A. 684.  
 culture, formation of composts for, U.S.D.A. 596.
- Musk ox in Alaska, U.S.D.A. 500.**
- Muskmelons**—  
 breeding, N.Y.State 626; U.S.D.A. 625.  
 disease-resistant, development, Calif. 790.  
 fertilizer requirements, Ark. 381.  
 irrigation, 332.  
 keeping quality, effect of waxing, Ariz. 38.
- Muskrats**—  
 parasites in British Isles, 652.  
 raising, U.S.D.A. 356.
- Mustard seed, germination, 787.**
- Mutation**—  
 new, in mice, gray-lethal, 776.  
 new satin, of rabbits, 776.  
 rate, increased, temperature as factor in, 19.
- Mutillidae, new genera and new species, 369.**
- Mycobacterium tuberculosis***—  
 avium, recoverability from experimentally infected guinea pigs, 101.  
 effect of hot hypochlorites of low alkalinity, 102.  
 in oily excipients, subcutaneous inoculation experiments with calves, 849.
- Mycorrhiza, significance, 462.**
- Mycorrhizas of healthy and mosaic potato plants, 56.**
- Mycosphaerella***—  
 arachnoidea n.sp., description, 647.  
 fragariae, notes, U.S.D.A. 803.  
 sentina, susceptibility of pear varieties to, 61.  
 tulipiferae n.comb., notes, 637.
- Myobia* n.sp., notes, 652.**
- Myriangium* spp. on citrus, 648.**

- Mystrosporium adustum* on *Iris recticulata*, control, 352.
- Myzocallis ulmifolia*, notes, Colo. 218.
- Myzus persicae*, see Peach aphid, green.
- Nails, holding power, 254.
- Naphthalene—  
chlorinated, as ovicide for codling moth and oriental fruit moth, 363.  
effect on *Heterodera schachtii* infected soil, 58.  
effect on rice germination, 622.
- Napier grass—  
cutting tests, Hawaii 780.  
digestibility, Hawaii 835.  
v. Sudan grass, value, Hawaii 841.
- Narcissus—  
bulb scale mite as pest, 513.  
bulbs, forcing, relation to storage temperature, [N.Y.]Cornell 800  
bulbs, presoaking before treatment with hot water and fungicides, effects, 353.  
diseases, [N.Y.]Cornell 804.

crown rust, reaction of Victoria variety to, 199.

hay poisoning, 693; Colo. 533.

loose smut, effect on seed hulling, 199.

mill feed as hay substitute for dairy cows, value, 526.

pastures for fattening pigs, Tex. 517.

products, industrial utilization, 178.

rust, control, Tex. 487.

rust resistant hybrid selections, 20.

seedlings, growth and phototropic response, 601.

smut, control, Ga. 339, 343.

smut, laboratory detection, 343.

smut resistance, breeding for, Mo. 618.

smut resistant hybrid selections, 20.

smut resistant Markton variety, effect of latent infection, 489.

smuts, studies, 342, 488.

**Oats—**

acresages, yields, and total production, U.S.D.A. 712.

and vetch mixtures for hay, tests, Calif. 780.

as grain for hens, feeding experiments, 87.

breeding, Colo. 468; [N.Y.]Cornell 780; Tenn. 29; Tex. 468; U.S.D.A. 617.

breeding for disease resistance, Ga. 323.

culture experiments, Ark. 617; U.S.D.A. 617.

fall growth, analyses, Ky. 29.

fatuoid, origin, hybridization theory, 20.

fertilizer experiments, Tex. 469.

for hay, tests, Mont. 618.

improvement, U.S.D.A. 617.

in North Dakota, N.Dak. 326.

light growth response and auxin curvatures of, 166.

losses from diseases in 1935, U.S.D.A. 339.

production-consumption balance, Mich. 709.

production in Colorado, Colo. 32.

sprouted, effect on reproduction of dairy cattle, 526.

superior germ plasma in, U.S.D.A. 26.

**Oats—Continued.**

varieties, clipping tests, Ariz. 29.

varieties of Nova Scotia, analysis, 624.

variety-date-of-planting test, Ariz. 29.

variety tests, Ariz. 29; Ark. 617; Mo.

618; Mont. 618; N.Dak. 326; Tenn. 29; Tex. 468.

vernalization experiments, 27.

vitamin D in, 888.

winter hardiness experiments, Ark. 617.

yields after legumes interplanted in corn, Ark. 617.

yields, effects of summer soil-conserving crops on, U.S.D.A. 328.

**Oberly Memorial Prize, notes, 432.**

*Oebalus pugnax*, notes, U.S.D.A. 654.

*Oesophagostomum venulosum*, notes, 394.

**Oestrin—**

action on the vagina during lactation, 321.

ante-natal administration to female rat, effect, 322.

concentration in urine throughout pregnancy in mare, 779.

effect on ovaries of immature rats, 321.

injections, effect on accessory reproductive organs of male ground squirrel, 618.

injections, effect on balance between prehypophyseal gonadotropic hormones of male rat, 321.

injections, effect on pituitaries of immature female rats, 321.

injections in rats, effects, 614.

Oestriol, sterilization in rabbits by, 616.

*Oestrus ovis*, see Botfly, sheep.

Oestrogenic nature of materials in manure, action on plant growth, 601.

**Oestrone—**

effect on galactin of male rat pituitaries, 466.

sterilization in rabbits by, 616.

Oestrous reaction, participation of ovarian factors other than oestrin in, 777.

**Oestrus—**

experimental constant, and notion of antigonadotropic hormones, 466.

experimental induction in normal and ovariectomized guinea pigs, 616.

in cattle, periodicity and duration, 837.

induction in senile mare, Mo. 613.

Office of Experiment Stations report, 1936, editorial, 289.

*Ogmocoris reingeri* n.sp., description, 828.

**Oil—**

burners for home heating, U.S.D.A. 550.

crops, new, 178.

emulsifiers and spreaders, studies, 67.

meal, see Linseed meal.

sprays, physiological effects on fruit trees, 40.

sprays, tank-mix, improvements in, Calif. 824.

**Oils—see also Fats and specific oils.**

and oil emulsions, U.S.D.A. 655.

application by atomization and relation of viscosity to drop size, 504.

## Oils—Continued.

- drying, competition between linseed and others, Calif. 262.
- drying, studies, U.S.D.A. 579.
- mineral, as mosquito larvicides, 76.
- tropical, sterols of, Hawaii 740.
- vegetable, keeping quality, U.S.D.A. 667.

Oleomargarine, *see also* Margarine.  
situation, 407.

*Olethreutes abietana*, control, N.Y.State 656.

## Olive—

- knot or tuberculosis, Calif. 808.
- llothrips, biological study, 218.
- oil, tea-seed oil in, detection, 439.

Olives, processing, Calif. 740.

## Onion—

- flavor, occurrence in meat, Ga. 370.
- maggot, [N.Y.]Cornell 820.
- mildew, control, [N.Y.]Cornell 804.
- thrips, fungus infesting, 67.
- thrips, notes, 60; [N.Y.]Cornell 820;  
S.C. 217; Tex. 502; U.S.D.A. 654.
- thrips, toxicity of nicotine and soap to, 69.
- thrips, vectors of spotted wilt of sweet pea, Calif. 649.

## Onions—

- curing and storage, Colo. 476.
- effect of manganese and copper, 761.
- insects affecting, Ind. 503.
- Spanish type, breeding, Colo. 476.
- strains, Colo. 476.
- temperature requirements, Mont. 632.
- thrips-resistant, development, Calif. 790.
- yield and cost of production, Mich. 708.

*Ooencyrtus batocerae* n.sp., description, 80.

*Ophiobolus graminis*—

- development, growth factor affecting, 841.
- nitrogen utilization by, 809.

Ophi, nutritive value and mineral and vitamin content, Hawaii 877.

*Opuntia polyacantha*, root sprout method of reproduction, 788.

## Orange—

- beverages, dairy, vitamin C in, 527.
- flowers, chemical composition, 799.
- fruit scab fungus, perfect stage, 498.
- juice and orange products, vitamin C in, Conn.[New Haven] 272.
- juice, preservation, 298.
- mottle-leaf, specific effects of zinc on leaves and twigs, 352.
- sweet, fruit scab, U.S.D.A. 634.
- tortrix, biology, 660.

## Oranges—

- Chinese varieties, vitamin C in, 278.
- effect of carbon dioxide treatment on storage and transit diseases, U.S.D.A. 51.
- granulation, 837.
- harder kinds, breeding, Tex. 476.
- irrigation requirements, Calif. 790.
- navel, water rot, relation to pest control treatment, 498.
- storage, Tex. 476.

## Oranges—Continued.

- vitamin C potency, effect of storage, 278.
- Washington Navel, pruning, 482.
- Washington Navel, use of water by, Ariz. 482.
- yields, effect of interplanting summer soil-conserving crops, U.S.D.A. 823.

## Orchard—

- blowers for frost protection, 861.
- cover crops, N.Y.State 629.
- grass, time for seeding, Vt. 178.
- insects, trends in, 826.
- pests, control, 826.
- soils and sites, good, characteristics, Mich. 625.

Orchards—*see also* Fruits, Apples, Peaches, *etc.*

- management, N.Y.State 629.
- soil moisture studies, 792.
- spraying, stationary equipment for, Ohio 40.

*Orchestia platensis*, intermediate host for *Hymenolepis exigua*, 822.

Orchids and orchid seed, studies, [N.Y.]Cornell 764.

Oregon College, notes, 286.

Oregon Station, notes, 286.

## Organic matter—

- decomposing, base exchange capacity, 308.
- decomposition, relation to soil fertility in arid and semiarid regions, 756.
- in soil and organic carbon, simultaneous determination, 582.
- in soils, decomposition, CO<sub>2</sub> evolved by, apparatus for measurement, 450.
- in soils, relation to cultural systems, 788.

Organisms—*see also* Bacteria and Micro-organisms.

- respiratory intensity, relation to water content and colloidal state of protoplasm, 806.

Organo-phosphates as potential fertilizers, 178.

*Orius insidiosus*, predatory enemy of flower thrips, S.C. 217.

Ornamental plants, shrubs, and trees, *see* Plants, Shrubs, and Trees.

*Ornithodoros*—

- hermsi*, vector of relapsing fever, 370; Calif. 849.
- turicata*, starvation record of five years survival, 514.

Ornithology, economic, correlation of laboratory and field methods, U.S.D.A. 356.

Ortalid fly, notes, U.S.D.A. 654.

*Ostertagia*—*circumcincta*—

- in lambs in southwest Britain, 251.
- in sheep on irrigated pastures, seasonal incidence, Calif. 848.
- notes, 394, 395.
- sp., infestation of grazing sheep, effect of salting of pasture, 251.

*Otiorrhynchus* spp. on strawberries, first instar larvae, 511.

- Ova—**  
 mammalian, comparative behavior in vivo and in vitro, 320.  
 rabbit, changes in size before and after fertilization, 25.  
 rabbit, fertilized and unfertilized, development in vitro, 24.  
 rabbit, hybrid fertilization in vitro, 24.
- Ovarian—**  
 cyst in parakeet, 857.  
 reactions of cows to gonadotropic hormone preparations, 175.  
 transplants, effect on seminal vesicle and prostate gland, 615.
- Ovaries—**  
 immature rabbit, reactions to gonadotropic extracts, 321.  
 immature rat, effect of pregnancy urine extract and oestrin, 321.  
 of birds, follicular epithelium, chromosomal elements, 613.  
 of hypophysectomized immature rats, follicular apparatus and effects of hypophyseal gonadotropic hormones, 615.
- Ovifollin administration to hens for sex control in chicks, 617.
- Ovulariopsis goosypii* on cotton in Peru, 642.
- Ovulation—**  
 in ewes, Mo. 613.  
 in hens, effect of light, 379.
- Ovum** age and course of gestation in guinea pig, 465.
- Owl, eastern screech, *Plasmodium oti* from, established in canaries, 653.
- Owl, short-eared, winter food, 211.
- Owls, virus disease of, 108.
- Ox** serum, protein changes induced by hyperimmunization against rinderpest virus, 391.
- Oxidation-reduction** potentials in biological fluids, convenient resistance for determination, 151.
- Oxyspirura mansonii*, intermediate hosts, Hawaii 820.
- Oystershell scale, control, N.Y.State 656.
- Oystershell v. mussel shell for laying hens, 88.
- Paint, effectiveness as protective coatings for wood, 256; U.S.N.A. 254.
- Paints, low cost, and surface treatments. Mich. 699.
- Palm-kernel oil meal, effect on percentage of fat in milk, [N.Y.]Cornell 841.
- Pangenesis, hypothesis as explained by Darwin, 175.
- Pantagathus* new genus, erection, Tex. 77.
- Papaya—**  
 diseases, virus, in Kwangtung Province, 195.  
 fixation of flower type in, Hawaii 790.  
 improved strains, selection, Hawaii 790.  
 nutritive value and vitamin content, Hawaii 877.
- Paper, book and record, deterioration, U.S.D.A. 586.
- Paracarbaminophenylarsonic acid, action on intestinal trichomonads of rats, 392.
- Paracasein, solubility, effect of salts, 686.
- Paraffin embedding, electrically heated needle for, 764.
- Paralysis—**  
 fowl, incidence according to family, 675.  
 fowl, outbreaks and transmission, 849.  
 fowl, studies, 243, 854; Mo. 689.  
 fowl, transmission, 107.  
 in chicks, differentiation, 675, 697.  
 in crosses of large breeds of dogs, 775.  
 infectious bulbar—  
   size of virus, estimating by ultrafiltration analysis, 534.  
   transmission experiments by bite of an infected animal, 247.
- Paramecium—**  
 and *Didinium*, interaction between, 213.  
 and yeast cells, interaction between, 213.
- Parasites—**  
 abomasal, in lambs of southwest Britain, 251.  
 animal, control, treatise, 244.  
 animal, studies, Ky. 97.  
 animal, survival under tropical conditions, effects of natural factors, P.R. 848.  
 avian, control with anthelmintics, Ark. 696.  
 Diprion, introduction into Canada, 667.  
 insect and cryptogamic, of plants, control, 803.

varieties, Colo. 476.

variety tests, Ga. 381.

- Plutella maculipennis*, see Diamondback moth.
- Pneumonia—  
in calves, Mich. 689.  
in lambs due to *Bacterium mastitidis*, 250.
- Pod borers, notes, U.S.D.A. 654.
- Podonectria* spp. on citrus, 648.
- Poisonous plants, see Plants, poisonous, and specific plants.
- Poisons, stomach, toxicity to insects, 503.
- Pole timbers, Australian, selection, preservation, distribution, and identification, 403.
- Poliotomyia* new genus, erection, Tex. 77.
- Pollen—  
grains, compound, in *Datura*, gene for, 19.  
radiation with ultraviolet rays, production of genetic variations by, Mo. 618.  
tube growth in *Datura*, genes affecting, 19.
- Polychorus viteana*, see Grape berry moth.
- Polydactyly in guinea pigs, 19.
- Polyhalite as source of potash for fertilizers, Tex. 446.
- Polynuritic chicks—  
anaerobic glycolysis in tissues from, effect of vitamin B<sub>1</sub>, 840.  
effect on rate of removal of pyruvate injected intravenously, 841.  
lactic acid metabolism in tissues from, 840.  
pyruvic acid metabolism in, action of crystalline vitamin B<sub>1</sub>, 840.
- Polyplax* sp., notes, 652.
- Polyploidy, induced in wheat and rye, 22.
- Polyporus*—  
*hispidus*, effect on timber, 819.  
*squamosus*, black lines in elm wood formed by, 807.  
*vaporarius*, protecting wood against, 650.  
*versicolor*, carbon dioxide production and growth in continuously aerated malt-agar cultures, 457.  
*versicolor*, effect on properties of red gum sapwood, U.S.D.A. 499.
- Polythelia in dairy cattle, Mo. 679.
- Pomace fly, oviposition, effect of temperature, 222.
- Popcorn—  
bacterial wilt, Tex. 488.  
popping, relation to age and viability, N.Y.State 32.
- Popillia japonica*, see Japanese beetle.
- Poplar—  
balsam, wounding, activity of vascular cambium in relation to, 766.  
bark canker, 818.  
yellow, germination and survival, Ga. 837.  
yellow, variations in wood from southern Appalachian region, 338.
- Population—  
and nationality groups in Michigan, Mich. 718.  
and sources of labor and use of supplies in Wales, 868.
- Population—Continued.  
growth, relation to land use and relief, Ky. 117.  
in Virginia, mobility and changes, 372.  
mobility in rice area of Louisiana, 415.  
rural, of Ohio, trend of births, deaths, natural increase, and migration in, 125.  
trends in Minnesota, Minn. 415.
- Pork—  
brain and kidney, vitamin B<sub>1</sub> in, 516.  
cost of production, Ky. 81; N.C. 119.  
curing and storing in west Texas, Tex. 517.  
lean, effect of cooking and canning on vitamin B and G in, 422.  
production, efficiency in, 520.  
quality, factors affecting, U.S.D.A. 667.  
work of Food Investigation Board of Great Britain, 877.
- Porometer—  
diffusion, 460.  
inexpensive recording, description, 311.
- Porthestia scintillans* in Canton, 660.
- Porthetria dispar*, see Gypsy moth.
- Postharmostomum* sp., notes, P.R. 856.
- Posts, durability, preservative treatment, Ark. 699.
- Potash—  
availability, effect of lime, Del. 589.  
in cropped soils, effect of fertilizers and lime, 11.  
production, U.S.D.A. 589.  
relation to thickness of fruit wall in pimiento peppers, Ga. 381.
- Potassium—  
action on nitrogen assimilation by plants, 603.  
determination, Mich. 579.  
distribution and condition in soil planted to apple trees in cylinders, 455.  
effect on transpiration rate in plants, 458.  
fertilization, effect on starch in potatoes, 472.  
in blood and in plant tissue, microdetermination, 372.  
in California soils, Calif. 752.  
in young apple trees, effect of potassium fertilizer, 41.  
iodide in poultry farming, 372.  
new analytical reagents for, N.Y.State 579.  
relation to citrus growth, 482.  
role in plant nutrition, 15.  
role of, Ark. 589.  
substitutes in metabolism of lowest fungi, 603.  
sulfate, effect on *Heterodera schachtii* infected soil, 58.
- Potato—  
aphid, transmission of bean-mosaic virus by, 659.  
bacterial wilt in fall plantings in Florida, U.S.D.A., 635.

## Potato—Continued.

beetle, Colorado, in North America, 223.  
 blight fungus, biological specialization in, 203.  
 blight, late, breeding for resistance to, 346.  
 blight, late, in eastern Virginia, U.S.D.A. 635.  
 blight-resistant varieties, breeding methods, 56.  
 brown rot, control, Fla. 346.  
 chips, deep-fat frying, relative value of fats for, 418.  
 curly dwarf in Colorado, 643.  
 diseases, Michigan, control, 493.  
 diseases, notes, Mich. 635.  
 diseases, virus, in Kwangtung Province, 195.  
 diseases, virus, therapy, 53.  
 flakes in rations for hens, 280.  
 flea beetle, control, 501.  
 flea beetle, relative toxicity of derris and pyrethrum steepates to, 66.  
*Fusarium* wilts, differentiation, and effect of environment, 346.  
 haulm, destruction to prevent tuber blight infection, 492.  
 industry on Long Island, relation to root knot nematode, N.Y.State 57.  
 land flooded by salt water, reclamation, 784.  
 leaf roll, losses due to, U.S.D.A. 635.  
 leafhopper on beans, control, 658.  
 leafhopper, relative toxicity of derris and pyrethrum steepates to, 66.  
 leaves, chlorophyll in, relation to chlorine, 171.  
 losses from diseases in 1935, U.S.D.A. 339.  
 mosaic, aucuba, symptoms and properties of virus, 492.  
 mosaic, infection of scion on resistant stock, reaction, 493.  
 mosaic viruses, Dutch and Irish, comparison, 492.  
 nematodes, action of hypochlorite solutions, 354.  
 plants, flowering, effect of length of dormant period, 33.  
 powdery mildew in New Jersey, 204.  
 psyllid yellows and early blight, Ariz. 46.  
 scab, [N.Y.]Cornell 804.  
 scab, breeding for resistance to, 643.  
 scab control by mercury compounds added to fertilizers, 204.  
 scab control by soil application of sulfur, Tex. 487.  
 scab control in western New York, 204.  
 scab, effect of irrigated crop rotations, 204.  
 scurf, notes, 53.  
 seedlings, new, tests, Mich. 618.  
 sickness control on *Heterodera schachtii* infected soils, 57.  
 sorting table, home-made, 116.

## Potato—Continued.

spotted wilt disease, transmission by thrips, 641.  
 sprout emergence, relation to fertilizer placement, 620.  
 tuber worm, notes, Tenn. 65.  
 tubers, blackening of flesh, 810.  
 tubers, gray necrosis, 58.  
 tubers, heart necrosis, cause, 56.  
 tubers, isolation of citric acid from, 608.  
 virus "X" inactivated by nitrous acid, production of antisera with, 485.  
 virus "X" infectivity, relation to serological reactions, 345.  
 viruses causing top necrosis, 810.  
 yellow dwarf, [N.Y.]Cornell 804.  
 yellow dwarf virus, inoculation on seedlings with, 845.

## Potatoes—

acres, yields, and total production, U.S.D.A. 712.  
 bibliography of, 472.  
 blackening on cooking, relation to fertilizer composition, U.S.D.A. 716.  
 breeding, 182; Colo. 468; [N.Y.]Cornell 780; U.S.D.A. 617.  
 cooking qualities, factors affecting, Me. 559.  
 culinary quality, Colo. 561.  
 cultural and storage studies, [N.Y.]Cornell 780.  
 culture experiments, Tex. 468; U.S.D.A. 617; W.Va. 781.  
 date of digging, relation to development of *Rhizoctonia*, 57.  
 degeneration, 493, 643, 810.  
 degeneration, relation to leaf roll and streak, 203.  
 degeneration, struggle against and theory of plant development, 203.  
 early Irish, cost of production, N.C. 120.  
 effect of copper, manganese, and zinc, 761.  
 effect of freezing on antiscorbutic activity, 886.  
 effect of irrigation and time of planting, 53.  
 experimental culture in Morocco, 784.  
 feeding value for chickens, Mich. 676.  
 fertilizer experiments, Ark. 617; Hawaii 780; Ky. 29; [N.Y.]Cornell 780; S.C. 472; Tex. 469; W.Va. 781.  
 fertilizer placement tests, 620; U.S.D.A. 617.  
 fertilizer requirements, Ark. 331.  
 fertilizer use, changes in, 784.  
 for chickens, Ohio 230.  
 grown in controlled environment, variations in yield, N.H. 182.  
 growth rate and yield, effect of bordeaux spraying, 346.  
 in Hood River Valley, effect of fertilizers, Oreg. 621.  
 insects affecting, Ind. 508.

## Potatoes—Continued.

- insects attacking on Long Island, [N.Y.]Cornell 820.
  - Italian varieties, response to viruses, 56.
  - Katabdin, yield, effect of tillage practices, 472.
  - liming experiments, 784; W.Va. 781.
  - mycorrhizas of healthy and mosaic tubers, 56.
  - nematodes affecting, 810.
  - planting test, Ky. 29.
  - production and research, 182.
  - production in Canada, 784.
  - respiration, relation to concentration of sugars, 15.
  - response to crop rotations and fertilizers, 83.
  - root knot nematode of, N.Y.State 636.
  - seed, certified, production, cooperation in, Ariz. 46.
  - seed, treatment with yellow oxide of mercury, N.Y.State 56, 636.
  - spraying experiments on muck land, [N.Y.]Cornell 820.
  - spraying, factors affecting efficiency, [N.Y.]Cornell 804.
  - starch content, effect of potassium fertilization, 472.
  - steamed and raw, comparison for fattening pigs, 376.
  - storage, U.S.D.A. 542, 698.
  - stored, fungus disease, 204.
  - varieties, hill selection method of study, 53.
  - varieties, new, determining value, 33.
  - variety tests, Ga. 823; Hawaii 780; Ky. 29; Tenn. 29; Tex. 468.
  - washing experiments, Wash. 258.
- Poultry—*see also* Chickens, Chicks, Ducks, Fowls, Hens, *etc.*
- adult mortality from viewpoint of genetics, 23.
  - and egg business, treatise, 678.
  - Barred Plymouth Rock, growth rate, inheritance, 464.
  - blindness, incidence according to family, 675.
  - breeding, feeding, and management studies, U.S.D.A. 667.
  - breeding, production of superior stock, U.S.D.A. 24.
  - breeds, size correlation with glutathione concentration, 322.
  - brooder houses, air conditioned, 862.
  - brooders, electric v. coal for winter broiler production, Mich. 668.
  - cell inclusion disease, minor outbreak, 397.
  - costs and returns, monthly, 551.
  - cross-breeding for meat and egg production, Hawaii 835.
  - dark pigmentation in White Silkies, sex-linked recessive gene for, U.S.D.A. 612.
  - development of resistance to *Eimeria tenella*, age as factor, 251.

## Poultry—Continued.

- disease control programs for future, 675.
- diseases—*see also specific diseases.*
- diagnostic service, Mo. 689.
- in Cyprus, 541.
- in Sweden, 853.
- notes, 858.
- respiratory, N.J. 395, 396.
- farming, potassium iodide in, 372.
- farms, economic study, Md. 554.
- farms of Massachusetts, labor efficiency, 675.
- feeds, Arizona, comparison, Ariz. 81.
- feeds, mineral requirements, Tex. 517.
- hardiness, relation to abnormal incubation temperatures and genetic constitution, U.S.D.A. 612.
- house, Connecticut 24' x 24'. 675.
- houses, air-conditioning in, [N.Y.]Cornell 857.
- houses, disinfection with fire guns, Mich. 689.
- houses for Manitoba, 117.
- housing, Ark. 699; Mo. 699.
- housing plan service, problems in creating, 675.
- housing problems of Texas, 675.
- housing, relation to respiratory problems, 675.
- housing, trends in, 675.
- inheritance of rate of laying, 177.
- management, comparison for chicks, layers, and breeding hens, La. 521.
- meat, quality in, 676.
- meat stock, composition of thigh muscle, relation to proteins in rations, 675.
- milk fattening ration, 87.
- molasses as feed for, La. 837.
- mortality in, economic aspects, 853.
- nutritional requirements, Mo. 668.
- packing house byproducts in diet, effect, 877.
- parasites, U.S.D.A. 689.
- parasites in Puerto Rico, treatment, P.R. 856.
- parasites, internal, in Puerto Rico, P.R. 105.
- pasture crops for, comparison, Mich. 668.
- plucking, use of wax in, 841.
- poisoning, danger from arsenic in grasshopper bait, 359.
- potatoes and potato flakes for, 230.
- potatoes as feed for, Mich. 676.
- products, cost of production, N.C. 119.
- protozoal disease, fatal, Calif. 849.
- quick frozen by Z process, marketing, 525.
- rations, lupine meal for, 230.
- roundworms, tobacco dust treatment for, 397.
- sanitation, six-point programs for, 675, 695.
- Science Association, meeting, 675.

## Poultry—Continued.

- Sebright Bantam, plumage, effect of testicular hormones, 779.  
 selection for production, Calif. 834.  
 varieties and strains, 676.  
 vitamin D requirement, 878.  
 vitamin G requirement, 425; [N.Y.] Cornell 378, 835; Ohio 523.  
 work of Food Investigation Board of Great Britain, 877.  
 yards, disinfection, 857.
- Prairie chicken, management, experimental project, U.S.D.A. 356.
- Precipitation—*see also* Rainfall, Snow, *etc.*  
 effective, relation to crop yields, U.S.D.A. 6.  
 past, tree rings as records, Nev. 252.  
 preseasonal, relation to crop yields, 587.  
 Predators, depredations by, U.S.D.A. 500.
- Pregnancy—  
 anemia in, 729.  
 blood changes in, relation to iron and protein of diet, 275.  
 diagnosis, Tex. 463.  
 disease of sheep, pathogenesis, 693.  
 effect of diet deficiencies on fetus, 888.  
 in rats, physiology, 322.  
 test, urine, in cows, experiments, 467.  
 urine, effect on ovaries of immature rats, 321.
- Peromotrypes fractirostris*, new from South America, 512.
- Pressing, effect on weighted and unweighted silk, 891.
- Price indexes, Okla. 408.
- Pricklypear, *see* Cactus.
- Pringle, C. G., life and work, treatise, 600.
- Privet—  
 galls produced by species of *Phomopsis*, 818.  
 root rot, Tex. 488.
- Prodenia ornithogalli*, role in cotton wilt transmission, 809.
- Production trends and policies, 408.
- Progesterone—  
 effect on response of rabbit's uterus to pituitrin, 615.  
 large doses, effect on female rat, 467.  
 role in experimental induction of oestrus, 616.
- Progesterin, effect on response of rabbit's uterus to pituitrin, 615.
- Prolactin effect on—  
 broodiness in fowls, 25.  
 ovary and accessory sex organs of hens, 25.
- Promeochea antiqua* on coconut, 215.
- Propionic acid bacteria—  
 dissimilation of glucose by, role of phosphoglyceric acid in, 148.  
 essential growth factors for, 770.
- Prostate of rodents, effect of androsterone and male hormone concentrates, 780.
- Protein—  
 crystalline, with properties of tobacco mosaic virus, 206.  
 deficiency, 573.

## Protein—Continued.

- metabolism in infants and children, comparison with sulfur metabolism, 724.  
 solutions, refractivity, 579.  
 value of soybeans, studies, 669.
- Proteins—  
 and carbohydrates mixture in diet, effect on gastric secretion or digestion, 272.  
 biological value, 272, 879.  
 body and organ, determination, gravimetric methods, 749.  
 cystine, tryptophan, and tyrosine in, U.S.D.A. 579.  
 digestibility, U.S.D.A. 579.  
 disulfide groups in, immunological study of reduction, 741.  
 for milking cows, dried blood as source, Mass. 843.  
 from several sources, nutritive value for milk production, 382.  
 in animal tissues, nutritive value, U.S.D.A. 716.  
 intake, relation to utilization of energy, Mo. 515.  
 nutritive value for lambs, [N.Y.] Cornell 835.  
 plant and animal, comparison for blood plasma regeneration, 502.  
 studies, N.Y. State 579.  
 vegetable, effect on laying activity of hens, 523.
- Protoplasm—  
 water content and colloidal state, dependence of respiratory intensity of organisms on, 606.  
 water permeability of and ion action, 17.
- Protozoa—  
 parasitic in wild rats in Baltimore, 212.  
 soil count, effect of different media, 598.  
 staining technic, improvement, Mich. 213.
- Provitamin D of heat-treated cholesterol, 82.
- Prune—  
 cans, corrosion, effect of sulfur sprays, Oreg. 581.  
 die-back, Calif. 803.  
 driers, installing forced draft in, 116.  
 trees, closely planted one-year-old, phosphate response with, 334.
- Prunus cerasifera* rootstocks, value, 41.
- Prussic acid poisoning of livestock, Colo. 97.
- Psallus seriatus*, *see* Cotton flea hopper.
- Pseudococcus*—  
*brevipies*, *see* Mealybug, pineapple.  
*citri*, *see* Mealybug, citrus.  
*maritimus*, *see* Mealybug, grape.
- Pseudolaria amabilis*, new host for *Dasyphypha wilkommii*, 818.
- Pseudomonas*—  
*aucubicola* n.sp., notes, 648.  
*citri*, *see* Citrus canker.  
*medicaginis phascolicola*, notes, 401.  
*tumefaciens*, biology, 638.
- Pseudoperonospora humuli*, notes, 636; U.S.D.A. 803.
- Pseudosinella violenta* in Iowa, biology, 826.

- Pseudotachinomyia*, generic characters and key to species, Tex. 77.
- Psoroptes ovis*, see Sheep scab mite.
- Psychoda*, American species, 76.
- Payllids, injurious, in Tanganyika, control, 218.
- Pteromalus puparum*, notes, 219.
- Public finance problems in Zaleski Forest, 260.
- Puccinia*—see also Rusts and host plants.
- asparagi* in New Jersey, U.S.D.A. 339.
- glumarum*, biological races, incidence and distribution, 49.
- glumarum*, biological races on grasses, 50.
- glumarum tritici*, resistance of individual wheat varieties to, 343.
- spp., overwintering in mycelial or spore stages, 638.
- triticoia*, notes, 48, 49.
- triticoia*, physiologic forms, determination, 341.
- Pucciniastrum pustulatum*, notes, 803.
- Puerto Rico College Station, notes, 735.
- Pullets—
- blood calcium, effect of progynon B, parathormone, and thyrotropic hormone, [N.Y.]Cornell 777.
- disease- and parasite-free, livable, ready-to-lay, production, Ohio 524.
- grain feeding, methods, W.Va. 836.
- laying, continuous hopper feeding of corn and oats to, Mich. 230.
- mineral metabolism, 88.
- sexed and unsexed, comparison of growth, 382.
- vitamin A requirements, N.J. 522.
- yield and cost of production, Mich. 708.
- Pullorum disease—see also *Salmonella pullorum*.
- eradication, Mass. 107.
- in captive quail, 542.
- in turkeys, 109, 856.
- studies, 855; Calif. 849.
- testing in fowls, Mo. 689.
- Pulp and paper problems, U.S.D.A. 632.
- Pulses, Indian, studies, 21.
- Pump, centrifugal, home-made, description, Mont. 400.
- Pumping, studies, U.S.D.A. 542.
- Pumpkin soft rot, description, 347.
- Pumpkins, effect of time of fruit set and harvest, N.Y.State 625.
- Purple scale, predator enemy of, 357.
- Puto spinosus*, injurious to mango flowers and fruits, 71.
- Pycnometer, precision, for liquids, 746.
- Pyrausta nubilalis*, see Corn borer, European.
- Pyrethrins and rotenone, toxicity, comparison, 66.
- Pyrethrins I and II, relative toxicity to insects, 825.
- Pyrethrum—
- a new crop, 178.
- and derris steepates, relative toxicity to potato insects, 66.
- Pyrethrum—Continued.
- chemical studies, U.S.D.A. 655.
- crown rot, plant losses due to, effect of irrigation practices, 44.
- culture, harvesting, and methods of analysis, 337.
- dusts for insect control, Colo. 501.
- dusts, stored, decreased effectiveness, 360.
- flowers, variation in, Colo. 43.
- flowers, yield, effect of spacing, 43.
- growing and harvesting, U.S.D.A. 625.
- harvester, U.S.D.A. 542.
- harvesting, 258.
- high-yielding strains, development, Tenn. 38.
- improvement, Colo. 470.
- in Tennessee, Tenn. 337.
- oil extract for lungworms, W.Va. 849.
- powder, degree of fineness, effects, 657.
- Pyrophorus luminosus*, notes, 658.
- Pyruvic acid—
- fermentation by bacteria of colon-aerogenes group, 4.
- isolation from blood of vitamin B<sub>1</sub>-deficient pigeons, 298.
- Pythium*—
- arrhenomanes*, notes, 493.
- attack on swede seedlings, temperature study, 847.
- debaryanum*, notes, Conn.[New Haven] 206.
- graminicolum* and *P. arrhenomanes*, differentiation, 347.
- spp., notes, 497.
- spp., physiological and cytological research, 312.
- Quail—
- bobwhite, fluctuations in population in South, 398.
- breeding, modern methods, U.S.D.A. 355.
- captive, pullorum disease in, 542.
- disease in upland game birds, 398.
- diseases, control, U.S.D.A. 500.
- management, experimental project, U.S.D.A. 356.
- raising, 211.
- research in New York State 821.
- Quince—
- industry, damage from oriental fruit moth, N.Y.State 75.
- rootstocks, percentage of rooted shoots to be expected from mother plantations, 792.
- Quinces, propagation, N.Y.State 629.
- Rabbit—
- cross, tame-wild, 776.
- drives, organizing and conducting, U.S.D.A. 356.
- Experiment Station at Fontana, Calif., work at, U.S.D.A. 500.
- fur studies, U.S.D.A. 500.
- ova, fertilization in vitro, 24.
- ova, stimulation and development in vitro, 320.

**Rabbit—Continued.**

- parasites in Australia, relation to parasitic infection in sheep, 851.
- population, control experiments with myxomatosis cuniculi, 849.

**Rabbits—**

- and cavies, periodicals on, U.S.D.A. 356.
- Angora wool, data on, U.S.D.A. 356.
- average weight at weaning age, U.S.D.A. 856.
- breeding when suckling young, results, U.S.D.A. 465.
- color characters and their histological basis, 24.
- cottontail, reproduction function in, 855.
- effect of hysterectomy, 24.
- feeding schedule, U.S.D.A. 356.
- for determining palatability of newly introduced forage plants, 227.
- inbreeding experiments, U.S.D.A. 612.
- lop-eared, inheritance, 317.
- nutritional requirements, Mo. 668.
- satin, a new hair mutation of, 776.
- sterility in, produced by injections of oestrone, 616.
- tumorlike condition, 109.
- young, and does during suckling period, relative weights, U.S.D.A. 356.

**Rabies—**

- among hematophagous bats, 535.
- diagnosis and control, U.S.D.A. 688.
- diagnostic service, Mo. 689.
- paralytic, transmission by vampire bat, 100.
- vaccine protection test, use of sheep in, 535.

**Raccoons—**

- food and breeding habits, 63.
- raising, U.S.D.A. 356.

**Radiation—see also Solar radiation.**

- mitogenetic, [N.Y.]Cornell 764.

*Taenia tenuicollis* of British muskrat, 652.

*Taeniothrips inconsequens*, see Pear thrips.

*Taeniothrips simplex*, see *Gladolus thrips*.

Tamarisk for fence posts, creosoting, Ariz. 109.

**Tankage—**

feeding, effect on milk flavor, 90.

supplemental value for pigs on rye pasture, Ark. 667.

Tannin in plant cells, physiology, 604.

Tanning materials, U.S.D.A. 579.

**Tapeworms—**

control, Mich. 689.

of poultry, P.R. 856.

of poultry, cysticeroid of, 107.

of poultry in Hawaii, *Orchestia platensis* as intermediate host, 822.

Tar oil sprays for apple pest control, 826.

Tarnished plant bug, notes, Tenn. 65.

**Taro—**

diseases, control, Hawaii 804.

processing, Hawaii 740.

producing areas, survey, Hawaii 780.

varietal and classification studies, Hawaii 780.

vitamin content and available calcium, Hawaii 877.

*Tarsonemus pallidus*, see Cyclamen mite.

**Tax—**

- delinquencies, decreases in, Ark. 705.
- delinquency, farm, and farm land assessments, Ky. 117.
- levies and public expenditures in Oregon, Oreg. 711.
- processing, on wheat, 555.

**Taxation**, town, in Vermont, Vt. 260.

**Taxes—**

- ad valorem, burden on producing and cut-over forest lands, Ark. 705.
- farm, 707.
- of farm real estate, index numbers, Calif. 264.
- town, variations in, [N.Y.]Cornell 411.

**Taxonomy**, procedure in, treatise, 356.

**Tea—**

- attacked by *Microtermes pallidus*, prevention, 658.
- effect on energy metabolism of children, Tex. 561.
- insect enemies in Ceylon, 657.
- seed oil, detection in olive oil, 439.

**Teats**, supernumerary, in dairy cattle, types, 175.

**Teeth—**

- composition, 730.
- decay and enamel hypoplasia, relation to rickets and vitamin D, 429.
- decay, susceptibility in rats, 730.
- effect of low levels of fluorine intake on, [N.Y.]Cornell 879.
- growth rate, effect of vitamin A deficiency, 724.
- of animals, variations and diseases of, 847.

**Telenomus nigrocoactis**, parasite of coconut caterpillar, 824.

**Telephone poles**, use of woods for, Tex. 483.

**Temperature—see also Climate and Soil temperature.**

- relation to variations of solar radiation, 5.

variation, eight-year periods, 588.

**Tenebrio molitor**, see Mealworm, yellow.

**Tenebrioides mauritanicus**, see Cadelle.

**Tennessee Station**, report, 141.

**Tennessee University**, notes, 432.

**Tent caterpillar—**

- eastern, notes, Tenn. 65.
- forest, notes, U.S.D.A. 654.

**Teosinte**, tetraploid strains, production, [N.Y.]Cornell 764.

**Tephritis finalis**, notes, 65.

**Termites—**

- distribution by greenhouse plants, 67.
- in United States, research, 827.
- notes, Mich. 655.
- Philippine, biological study, 658.

**Terrace outlet structures**, Mo. 699.

**Terraces—**

- design and construction for control of soil erosion, Ill. 253.
- measuring acres per mile of terrace and total acres benefited, 547.

**Terracing—**

- cost, Ark. 699.
- farm land cooperatively, cost, 551.
- in Southeast, new developments, 546.
- with power equipment, cost, 858.

**Testes**, structure in hybrids of yak and cattle, 774.

**Tetragonyssus spiniger**, notes, 652.

**Tetrameres—**

- americana*, intermediate hosts, Hawaii 820.
- americana*, notes, P.R. 856.
- crami*, life history, 398.
- crami*, parasite of ducks in North America, 398.
- graminis*, notes, Colo. 218.

**Tetranychus—**

- bimaculatus* control, bill posters' paste in sprays for, 501.
- telarius*, see Red spider.

**Tetrastichus**, Japanese species, 357.

**Teutana triangulosa** attacking brown dog tick, 226.

**Texas Station—**

- publications and articles by staff members, abstracts, 141.
- report, 575.

**Thallium—**

- effect on plant growth, U.S.D.A. 459.
- poisoning of dogs and fowls, effect of arsenical insecticides, 246.
- sulfate sirup as poison bait for household ants, 513.
- sulfate, toxicity for cattle, 103.

**Thaumetopoea pityocampa**, notes, 824.

**Theobaldia incidens**, nutritional requirements, 365.

**Thielavia basicola**, notes, Conn.[New Haven] 206.

**Thiodiphenolamine**, new ingredient of mosquito larvicides, 504.

**Thiourea**, effect on proximal dominance in sweetpotatoes, 785.

**Thorium alizarine sulfonate**, Ky. 4.

**Thresher** for seed beans, rubber as protective device on concave teeth of, 549.

**Thrips—**

- California Christmas berry, biology, 506.
- notes, U.S.D.A. 654.
- of Australia, 68.
- on cotton, studies, Tex. 502.

**Thrips—**

- imagineis*, notes, 69.
- spp., transmitting spotted wilt of lettuce and potatoes, 641.
- tabaci*, see Onion thrips.

**Thurberia weevil**, notes, U.S.D.A. 654.

**Thyroid—**

- desiccated, effect on vitamin C in guinea pig organs, 428.
- effect on metabolism and milk secretion, Mo. 679.
- human goitrous, iodine in, Ky. 130.
- role in calorogenic action of vitamin D, 727.

- Thyroxin**, effect on milk secretion and on phosphatase of blood and milk, 531.
- Thysanoptera**—  
collected in France, 827.  
common, of Australia, 68.  
in California, early knowledge previous to 1900, 827.  
of Iowa including four new species, 218.  
of Italy, 218.  
of the geenton, 361.
- Tick**—  
Gulf coast, biology and economic importance, 514.  
Pacific Coast, transmission of bovine anaplasmosis by, 249.  
winter, transmission of bovine anaplasmosis by, 249.
- Tick-borne fever of sheep**, transmission and distribution, 538.
- Ticks**—  
affecting man and animals, U.S.D.A. 654.  
eradication, U.S.D.A. 689.  
transmission, Calif. 848.  
winter feeding, production of artificial conditions conducive to, 656.
- Tilletia**—  
*horrida*, notes, U.S.D.A. 803.  
*tritici*—*see also host plants*.  
new physiologic races for Washington, Wash. 641.
- Timber**—*see also Lumber and Wood*.  
cutting, selection types, U.S.D.A. 632  
management, U.S.D.A. 632.  
properties, effect of fungus infection, 819.  
South African, weights of, 112.  
structural, decay in, 403.
- Timbrlakicilla**, new genus, erection, 667.
- Timothy**—  
growth, effect of shoot cutting, 178.  
meadows, fertilization, Mich. 185.  
selection for improvement in hay quality, 623.  
time for seeding, Vt. 178.
- Tin plate container**, corrosion by food products, 744.
- Tineola bisselliella**, *see* Clothes moth, webbing.
- Tiphididae**, catalog, 667.
- Tires**, low pressure pneumatic, for farm tractors and equipment, 405.
- Tissue**—  
culture studies on bacterial hypersensitivity, 533.  
enzymes, effect of vitamin B and G deficiencies, Ark. 716.
- Tissues**, human, copper and inorganic iron in, 421.
- Titration**, apparatus for, 749.
- Toad**, giant, in Barbados, status, 658.
- Tobacco**—  
acres, yields, and total production, U.S.D.A. 712.  
and products, toxicity of insecticidal combinations, U.S.D.A. 655.
- Tobacco**—Continued.  
blue mold, control by greenhouse fumigation, U.S.D.A. 684.  
breeding, 34; U.S.D.A. 617.  
budworm, control, 364; Conn.[New Haven] 214; U.S.D.A. 654.  
chemical studies, U.S.D.A. 655.  
cigar leaf, agronomic experiments, Conn.[New Haven] 185.  
cigar leaf, production, relation to absorption of plant nutrients, Pa. 34.  
cigar wrapper, variety tests, Tex. 468.  
cost of production, N C. 119.  
cured leaf, pests attacking, 214, 358.  
curly top virus, relation to plant tissues, 637.  
disease, new, 494.  
diseases, Ky. 46.  
diseases in 1935, Conn.[New Haven] 206.  
diseases in Virginia, U.S.D.A. 803.  
diseases, survey in Wisconsin, U.S.D.A. 339.  
diseases, virus, in Kwangtung Province, 195.  
downy mildew—  
or blue mold, control, 206.  
relation to weather, 347.  
sources of inoculum, 348.  
dust treatment, value for controlling roundworms in poultry, 397.  
extract as spreader of emulsifier in sprays, Ky. 65.  
fertilizer experiments, Ky. 29; N.C. 35; Tenn. 29.  
fertilizer placement tests, U.S.D.A. 617.  
flea beetle, control, Conn.[New Haven] 214; U.S.D.A. 654.  
flue-cured, burley, and dark, varietal studies, 786.  
Havana seed, time to harvest, Conn. [New Haven] 186.  
hornworm, notes, U.S.D.A. 654.  
industry, Canadian, trends in, 867.  
insecticidal use, U.S.D.A. 655.  
insects, notes, Ky. 65; Tenn. 825.  
leaf spots due to phosphorus deficiency, 58.  
leaves, glutamine and asparagine in, 580.  
liming tests, Ky. 29.  
mosaic, immunity studies, 812.  
mosaic in paniculata-like segregates from *Nicotiana paniculata* × *rustica*, necrotic response, 19.  
mosaic symptoms, low-temperature masking, 207.  
mosaic virus—  
chemical studies, 206.  
complex at isoelectric point, precipitation, 812.  
distinctive strains, comparison of derivatives, 645.  
gene governing type of response to, interspecific transfer, 812.

**Tobacco—Continued.**

- mosaic virus—continued.
  - genes affecting response of hybrids to, 813.
  - inactivation by ascorbic acid, 645.
  - inactivation by drying and by freezing in soil, 645.
  - inactivation by X-rays, 493.
  - material, Stanley's crystalline, relation to intracellular inclusions in infected cells, 645.
  - protein, crystalline, inactivation, 349.
  - protein, crystalline, stream double refraction of, 812.
  - protein, Stanley's crystalline, serological tests, 348.
  - protein, ultracentrifugal crystallization, 493.
  - reaction to pH of media containing it, 805.
  - resistance to radiation, 50.
- moth, notes, 214; U.S.D.A. 654.
- nicotine content, Ky. 29.
- ring spot, acquired immunity, relation to virus concentration, 207.
- ring spot acquired immunity, specificity, 349.
- ring spot, isolation by ultracentrifugation, 813.
- root rot resistance, inheritance, W.Va. 781.
- root rot resistance, strain tests, Tenn. 46.
- rotation experiments, Ky. 29.
- seed, disinfection against cryptogams, 206.
- seeds, germinating, toxicity of mercury vapor, 604.
- shade cloth, effect on atmospheric conditions, Conn.[New Haven] 187.
- sore shin in Kentucky, U.S.D.A. 46.
- superior germ plasm in, U.S.D.A. 26.
- thrips, Conn.[New Haven] 214; S.C. 217; U.S.D.A. 654.
- variety tests, Tenn. 29.
- virus diseases, infective principle and plant cell in, 812.
- webworm, notes, U.S.D.A. 654.

Toluol vapor for control of tobacco downy mildew in covered seedbeds, 206.

**Tomato—**

- bacterial canker, notes, U.S.D.A. 193, 339.
- black rot caused by *Alternaria* sp., 208.
- buckeye rot, notes, U.S.D.A. 193.
- disease, new, 814.
- diseases and insect pests, Hawaii 804.
- diseases, control, Tex. 487.
- diseases in Georgia, U.S.D.A. 635.
- diseases, virus, in Kwangtung Province, 195.
- foot rot control, Del. 635.
- fruit worm, *see* Corn earworm.
- fruits, puffing, nature of, Tex. 476.
- Fusarium* wilt, Mo. 636; Tenn. 46.

**Tomato—Continued.**

- Fusarium* wilt resistant strains, selection, Tex. 488.
  - insect survey, Calif. 824.
  - leaf spot resistance, breeding for, Tenn. 38.
  - leaf spots, control, Tenn. 46.
  - losses from diseases in 1935, U.S.D.A. 339.
  - mildew, cause of asthma, 494.
  - mosaic and cucumber mosaic, combined infection, effect on greenhouse tomatoes, 494.
  - nematode disease, new, 354.
  - pinworm, notes, 662; U.S.D.A. 654.
  - plants, cation and anion nitrogen absorption by, relation to oxygen and carbon dioxide of culture solutions, 759.
  - plants, hardening, retarding effect on yield and earliness, 628.
  - psyllid, relation to potatoes and tomatoes, Colo. 501.
  - roots, excised, growth, effect of vitamin B<sub>1</sub>, 769.
  - seed, pathogenic associates, 787.
  - spotted wilt virus, studies, 194, 805.
  - toe rot due to an unnamed species of *Phytophthora*, 208.
  - wilt resistance, relation to selection, Ga. 339.
  - wilt resistant varieties, Mo. 625.
- Tomatoes—**
- breeding, N.Y.State 626; Tex. 476; U.S.D.A. 625.
  - breeding for disease resistance, Ark. 625.
  - canning, costs, Wash. 717.
  - canning, storage losses in, 628.
  - color development in, [N.Y.]Cornell 791.
  - cracks in, causes, 628.
  - culture, Tex. 476.
  - culture and preparation for shipment, P.R.Col. 791.
  - decay during transit and storage, temperature studies, U.S.D.A. 59.
  - defoliation, 476; N.Y.State 636.
  - disease-resistant, development, Calif. 790.
  - early varieties, N.Y.State 791.
  - fertilizer experiments, Ga. 331.
  - fertilizer placement, N.Y.State 625.
  - fertilizer requirements, Ark. 331.
  - firmness and composition, effect of fertilizers, 331.
  - for canning, suggested set-up for washing and culling, 832.
  - fruit setting in midwinter, Mo. 625.
  - greenhouse, injury from combined infection with tomato and cucumber mosaic, 494.
  - growth and fruiting, Ark. 625.
  - growth and transpiration, effect of sprays, 477.
  - hybrid vigor, commercialization, 476.

## Tomatoes—Continued.

- in drying soil, nutrition, Ky. 88.
- irrigation requirements, Calif. 790.
- leaf area and fruit size, relation between, 89.
- nematodes affecting in Great Britain, 814.
- new greenhouse, breeding, Mich. 625.
- nitrogen requirements, Hawaii 790.
- resistant to *Cladosporium fulvum* leaf mold, U.S.D.A. 193.
- respiration, effect of oxygen and carbon dioxide concentrations, 606.
- uniform fruit color gene in, 772.
- varieties, testing, Hawaii 790.
- variety tests, Ga. 331; Ky. 38.
- vegetative anatomy, 461.

*Tomonotus astecus*, role in cotton wilt transmission, 809.

*Torosomyia*, new genus, erection, 77.

*Tortria*—

- excessana*, studies, 660.
- pallorana* injury to pines, 501; Mich 660.

## Towels—

- bath, buying, guides for, U.S.D.A. 893.
- turkish, physical and chemical properties, 431.

Towns of New York, receipts and expenditures, [N.Y.]Cornell 410.

Toxemia in sheep, Mo. 689.

Toxicogenic, term defined, 213

Toxiniferous, term defined, 213.

*Toxoptera graminum*, see Green bug.

*Trabutia erythrospora* from live oak, Tex 488.

*Trachelus tabidus*, notes, Ohio 214, 226.

## Tractor—

- engine lubrication under low temperature conditions, 860.
- fuel situation in Kansas, 112.
- tires, use of water in to increase draw-bar pull, 701.

## Tractors—

- conversion, Mich. 699.
- costs, Mich. 257, 708.
- low-pressure pneumatic tires on, 405.
- plowing with, laying out fields for, U.S.D.A. 257.
- tests, 404; Nebr. 860.

## Traffic—

- ordinances, model, U.S.D.A. 700.
- survey of Arkansas, digest of report, U.S.D.A. 112.

Translocation to sex-chromosome in *Apoteitia eurycephalus*, 19.

## Transpiration—

- and pressure deficit, 311.
- effect on absorption and distribution of mineral salts in plants, 458.
- in Mediterranean climate, diurnal fluctuations in, 18.
- modified by potassium, 458.
- stream in trees, thermoelectrical studies, 315.

## Tree—

- rings as records of past precipitation, Nev. 252.
- rings, width as index of physiological dryness in New England, 600.
- seeds, X-ray treatment, 633.
- workers, requirements for, Conn.[New Haven] 733.

## Treehopper—

- long-horned, of coconuts, 218.
- on apple, N.Y.State 656.

## Trees—

- calcium requirements and ecological distribution of species, correlation, [N.Y.] Cornell 801.
- coniferous, see Conifers.
- effects of illuminating gas in soil, 819.
- for planting in western Oklahoma, [Okla.]Panhandle 632.
- forest and shade, insects affecting, U.S.D.A. 654.
- forest, germination and seedling growth of species, Ark. 633.
- forest, in Adirondacks, five-year remeasurement of sample plots, 633.
- forest, leaves, trends in mineral content during growing season, 802.
- forest, rooting, factors in, [N.Y.]Cornell 801.
- forest, site indices determinations on various soil types, Ark. 633.
- gas-injured, effect of pruning roots, 650.
- growth and dormancy, effect of variation in length of day, 166.
- growth, radial and extension, 167.
- hardwood, dimension-stock mill for, equipping and operating, U.S.D.A. 338.
- hardwood, *Neotria* canker, [N.Y.]Cornell 804.
- hardwood, young, decay in, U.S.D.A. 634.
- in Kansas, effect of 1934 drought, 157, 483.
- injection experiments, 789.
- knot formation, method of study, 633.
- minimum sizes for economical cutting, U.S.D.A. 632.
- orchard, carbolineum emulsions for, stability and dispersion, 645.
- ornamental, drought injury to, 483.
- pneumatic systems, communication with atmosphere, 765.
- scars resulting from glaze on woody stems, 634.
- shade and ornamental, diseases, U.S.D.A. 803.
- shade, Japanese beetle control on, U.S.D.A. 366.
- shelterbelt, establishment, Mont. 632.
- shelterbelt, for farmsteads of northern Great Plains, U.S.D.A. 632.
- shelterbelt prairie, drought damage, Minn. 337.
- transpiration stream in, thermoelectrical studies, 315.

## Trees—Continued.

winter injured, inarching and bridge grafting as means of saving, [N.Y.] Cornell 791.

wounding, activity of vascular cambium in relation to, 766.

*Triatoma* spp., natural infection of American human trypanosomiasis in, 247.

*Tribolium confusum*, see Flour beetle, confused.

*Trichinella spiralis* in house rats, 213.

*Trichocephalus dispar*, notes, 394.

*Trichodectes*, forms, 504.

*Trichoderma lignorum*, repressive effects on red-leg disease of lettuce, 492.

*Trichogramma*—

*evanescens*, effect of superparasitism, 883.

*lutea*, parasite of cotton bollworm, 80

*minutum* for sugarcane borer control, 79  
species, two morphologically similar, biometrical study, 79.

Trichomonads of rats, action of carbarsone on, 392.

*Trichomonas*—

*foetus* infection in cattle, nonvenereal transmission, 249.

*parva* of wild rats, 212.

*Trichonema goldi* of horses in Brazil, 852.

*Trichophyton equinum* in hair from guinea pigs, fungicidal action of disinfectants, 240.

*Trichostrongyloides crassicauda* in house rats, 218.

Trichostrongylosis, medicinal treatment, 539.

*Trichostrongylus*—

*axei* in sheep, status and control, Calif. 849.

*axei* infestation of grazing sheep, effect of salting of pasture, 251.

*extenuatus* in lambs of southwest Britain, 251.

infection of calves, 250.

*tenuis* in partridges, 252.

*Trichuris*—

infection of calves, 250.

*ovis*, notes, 395.

*Trithaphis phaseoli*, distribution in South Atlantic States, 508.

*Trimerotropis citrina*, role in cotton wilt transmission, 809.

*Triosa merwei*, notes, 218.

Triploidy induction through hybridization, 19.

*Triticum*—

*aegilopoides*, cytogenetic studies, 19.

and *Agropyron*, hybridization, 610.

*monococcum*, cytogenetic studies, 19.

*Trogoderma versicolor*, fertility, 224.

## Trout—

nutritional requirements, [N.Y.] Cornell 820.

streams of Michigan, insect fauna, 66

## Truck crops—

culture, grading, and packing in Hawaii Hawaii 869.

diseases and insect pests, Hawaii 804

## Truck crops—Continued.

for exportation, culture, P.R.Col. 791.

on newly cleared land, nitrate requirements, 626.

on raised beds, movement and accumulation of soluble salts in, Ariz. 9.

variety tests, Hawaii 790.

Trucks, costs and methods of operation for fruit and vegetable marketing, [N.Y.] Cornell 863.

*Trypanosoma*—

*congolense*, equine, treatment with Surfen C, 105.

*congolense* in cattle, treatment with Antimosan and Surfen C, 108.

*cruxi*, natural infection of conenose bugs by, 247.

*lewisi* of wild rats, 212.

*neotomae* n.sp. in dusky-footed wood rat, 500.

Trypanosomiasis, diagnosis and control, U.S.D.A. 688.

Tryptophan in proteins, U.S.D.A. 579.

## Tubercle bacilli—

bovine, in lesions found in man, 248.

from dung on pasture, infectivity for healthy calves, 537.

virulent, recovery from swine tissues intended for food, 101.

## Tuberculin—

reactions in cattle with no visible tuberculous lesions on postmortem, 393.

sensitive tissues, 533.

use, U.S.D.A. 688.

## Tuberculosis—

avian, in cattle, 849.

bovine, studies, 243.

in bovines, sheep, poultry, and swine, U.S.D.A. 689.

in milk goats, 851.

of cattle in rearing districts of North Wales, 393.

of cattle, use of tuberculin in diagnosis and B. C. G. in vaccination, Calif. 848.

susceptibility of chickens to, 396.

unusual cases in various animals, 247.

Tuberculous animal cells, inherent sensitivity to tuberculin, persistence in vitro, 534.

Tuberose, bulb mite on, heat treatments for, 80.

## Tularemia—

of man, sheep, and other animals in British Columbia, 248.

spread through water, 692.

Tulips, broken or mosaic, flower color in, 498.

## Tumors—

in mice, transplantation, genetic studies, 175.

of domesticated animals in South Africa, incidence and pathology, 848.

plant, treatment with mitogenetic rays emitted by mosquito larvae, 806.

susceptibility of mouse strains to, 19.

## Tung-off—

- seedling blights, Tex. 486.
- studies, U.S.D.A. 579.
- trees, culture in Louisiana, La. 632.

Tunnel, midtown Hudson, soil pressures on lining, measurement, 401.

Turf, insects attacking, [N.Y.]Cornell 820.

## Turkey—

- eggs, artificial insemination with sperm from purebred and cross-bred chickens, U.S.D.A. 612.
- feeds, mineral requirements, Tex. 517.
- rations, effect of amounts of protein, Nev. 227.

## Turkeys—

- breeding, feeding, and management studies, U.S.D.A. 667.
- Bronze, breeding stock, feed consumption and cost of feeding, 525.
- cost of production, effect of rations, Mich. 668.
- effect of age of breeding stock and cross-breeding, Ky. 81.
- feeding and confinement rearing experiment, Mich. 235.
- growth in confinement, Mo. 668.
- inbreeding, Calif. 834.
- nutritive requirements, [N.Y.]Cornell 835.
- prices in Kentucky, relation to number in United States, Ky. 117.
- production, 678.
- protein requirements, Calif. 835.
- sex determination from hatching to maturity, 676.
- wild, management, 355.

## Turnip aphid—

- studies, Tex. 502; U.S.D.A. 654.
- vector of bean mosaic virus, 344.

Turnips, fertilizers for, Ariz. 38.

Turpentine, chemistry of, U.S.D.A. 579.

Tussock moth in Canton, 660.

Twins, pygopus parasitic bovine involving the udder, 466.

Tylenchidae, classification, key, 650.

*Tyloderma fragariae*, see Strawberry crown borer.

## Typhlocyba—

- australis* outbreak in Victorian orchards, 659.
- pomaria*, see Apple leafhopper, white.

Typhoid, mouse, role of bacteriophage in epidemics, 245.

*Typhula graminum*, physiology, 52.

Tuphus viruses, louse-borne and flea-borne, comparison, 392.

*Tyroglyphus* sp., notes, 652.

Tyrosine in proteins, U.S.D.A. 579.

## Udder—

- infections, relation to total production and composition of milk, N.Y.State 682.
- troubles in dairy cows, relation to incomplete milking, U.S.D.A. 239.

## Udders—

- mastitis organisms in, N.Y.State 659.
- nutritive value of protein in, 371.
- separate quarters, milk yield, U.S.D.A. 528.

Ulcers, production in rat pre-stomach, effect of nutrition, 562.

## Ultraviolet—

- light absorption by cellophane and by plant organs and tissues, 461.
- light, activatability of milk with, 527.
- light, effect on germination and development of wheat, 606.
- radiation, genetic effects in corn, 20.
- rays, effect on frequency of nuclear division in plants, 313.
- rays, effect on vitamin B carriers, Mo. 668.
- rays, modifications of cellular structure by, procedure for study, 311.
- rays, sporicidal action in dairy products, U.S.D.A. 528.

Umbrella tree heart rot, Ariz. 46.

*Underwoodia columnaris*, review of literature, 13.

Undulant fever, studies, Mich. 689.

United States Department of Agriculture—  
laws applicable to, supplement, 284.  
notes, 432.

- Office of Experiment Stations, see Office of Experiment Stations.
- report of Secretary, 732.
- Soil Conservation Service, see Soil Conservation Service.
- yearbook, 141.

Urea, use to stimulate healing in chronic purulent wounds, 690.

Urinary calculi, formation, relation to dietary constituents, 422.

## Urine—

- creatinine in and energy metabolism, 721.
- human, ascorbic acid excreted in, 427.
- human, excretion of vitamin B<sub>1</sub> in, relation to diet, 425.
- human, vitamins B<sub>1</sub> and B<sub>2</sub> in, 885.
- iodine determination in, 150.
- of cows, examination for *Brucella abortus*, 849.
- pregnancy tests in cows, experiments, 467.
- vitamin C in, effect of ingestion of acid and alkali, 567.
- vitamin C in, in health and disease, 568, 569.

*Urocystis tritici*, chlamydospore germination, cytological study, 13.

*Uromyces trifolii*, host specialisation, 494.

Uropygial gland and vitamin D deficiency in chicks, relation, 82.

## Ustilago—

- avenae* on oats, physiologic races, 199.
- nuda*, internal disinfection of barley seeds for control of, 52.
- spp. on *Erianthus* and *Saccharum*, 639.
- vulgaris*, effect on wood substances, 619.

- Utah College, notes, 897.  
 Utah Station, notes, 287, 896.  
 Utah Station publications and reprints of articles by staff members, 284.  
 Uterine growth, local, in untreated ovariectomized rabbits, 822.  
 Uterus, rabbit, reaction to pituitrin, 615.  
 Vacuum cleaners, electric, tests, Wash. 732.  
 Vaginal—  
   cornification induced by swabbing and bearing on rat unit of oestrogenic substance, 466.  
   epithelium of rat on excessive vitamin A diet, changes in, 884.  
*Valsa leucostoma*, notes, U.S.D.A. 46.  
 Vegetable—  
   diseases, Calif. 804.  
   diseases in Illinois, U.S.D.A. 339.  
   diseases in Massachusetts, U.S.D.A. 635.  
   diseases in Ohio, U.S.D.A. 193.  
   gardens, *see* Gardens.  
   oils, *see* Oils.  
   seed treatments, chart for 1936, U.S.D.A. 208.  
   weevil, studies, Ga. 358; U.S.D.A. 654.  
 Vegetables—  
   adaptation, Tex. 476.  
   cooking by gas and electricity, relative heat requirements, U.S.D.A. 716.  
   cooperative marketing, relation to motor transportation, Mich. 261.  
   culture at Mountain substation, Ga. 331.  
   disease-resistant, development, Calif. 790.  
   drying on farm, electric drier for, 116.  
   edible leafy, carotene in during storage, 725.  
   fertilizer requirements, 626; Hawaii 790.  
   fertilizers for, Ark. 625.  
   frozen, micro-organisms in, numbers and types, 878.  
   green, rich sources of vitamin K, 585.  
   grown on Long Island, fertilizer requirements, [N.Y.]Cornell 790.  
   handling and storage, [N.Y.]Cornell 791.

and lactoflavine, differentiation of anti-blacktongue factor, 424.

as rat anti-acrodynia factor, 425.

deficiency, type of skin lesion occurring in, 426.

differentiation of P-P factor from, 424.

**Vitamin B complex—**

carriers, effect of ultraviolet rays, Mo. 668.

effect on blood count and hemoglobin content of rats, 565.

filtrate factor, distribution, 81.

filtrate factor, effect of reagents on, 81.

for pellagra treatment, 886.

multiple nature of third factor, 839.

relation to disease, 881.

**Vitamin C—*see also* Ascorbic acid.**

action on blood vessels, 184.

and formation of intercellular material, 573.

assay, chemical and biological, 379.

## Vitamin C—Continued.

- chemistry, relation to behavior in body, 881.
- deficiency during pregnancy, 282.
- deficiency, heart rate in, 566.
- determination by means of 2,6-dichlorophenolindophenol, 155.
- determination, methods, 155, 426.
- distribution in different parts of foods of India, 887.
- excretion in human urine, 281, 427.
- excretions during periods of low and high vitamin C intake, 567.
- fate in digestive tract, 134.
- in alfalfa grown in South Africa, 429.
- in amaranth, Chinese varieties, 279.
- in apple varieties of Sweden, 727.
- in apples, factors affecting, 566.
- in blood and urine, forms, 569.
- in citrus fruits, U.S.D.A. 715.
- in dairy orange beverages, 527.
- in foods, assays, chemical and biological 279.
- in fruits, variation, 280.
- in guinea pig organs, effect of diet supplements, 428.
- in human milk, variation with diet, 887.
- in infants, studies, 282.
- in milk, 527.
- in milk, stability, factors affecting, 241.
- in orange products, Conn.[New Haven] 272.
- in oranges, Chinese varieties, 278.
- in organs of rat, effect of diets, 727.
- in peas, effect of shipping, freezing, and canning, 133.
- in potatoes, effect of freezing, 886.
- in redpepper, fresh and dried, 279.
- in rhubarb, raw, cooked, and canned 133.
- in sorrell juice, 886.
- in strawberry juice, Tenn. 125.
- in Szechwan fruits and vegetables, 726.
- in urine, effect of ingestion of acid and alkali, 567.
- in urine in health and disease, 568, 569.
- in vegetables, 280, 726.
- like substances, synthesis by fungi and bacteria, 312.
- potency of foods, effect of storage, 278.
- quantity for normal reducing value of animal tissues, 887.
- relation to pathological pigmentation 888.
- requirements during pregnancy and lactation, 134.
- requirements of plants, 165.
- role in the body, 133.
- synthesis in lens, mechanism, 280.

## Vitamin D—

- and embryo development, Ky. 81.
- and vitamin A, correlation, 276.
- assay, effect of seasonal variation, 522.
- calorigenic action, role of thyroid in, 727.
- constitution, 743.

## Vitamin D—Continued.

- deficiency during pregnancy, effect on fetus, 888.
  - deficiency in chicks and uropygial gland, relation, 82.
  - detection and determination, color reaction for, 440.
  - from various sources, antirachitic effectiveness, 82, 570.
  - in child health, 570.
  - in milk, effect of cacao shell feeding, 681.
  - in milk, effect of roughage, 526.
  - in pig rations, 376.
  - intake of hen, effect on bone calcification of chicks, 378.
  - irradiated and vitamin D yeast-fed milk, prophylactic value, 429.
  - magnesium, and phosphorus in ration, relation, Mich. 679.
  - milk, inspection and biological tests, Conn.[New Haven] 272.
  - milks, lack of uniformity in administrative control, 241.
  - relation to dental caries, enamel hypoplasia, and malocclusion, 429.
  - relation to urinary calculi, 422.
  - requirement of poultry, 378; Pa. 234.
  - requirements of calves, 238; Mich. 679.
  - sources, effect on laying hens, 233, 677.
  - studies in cattle, Mich. 238.
- Vitamin E—
- feeding, physiological responses, 429.
  - relation to fertility, 283.
- Vitamin F, see Vitamin B<sub>1</sub>.
- Vitamin G—
- and cystine, relation, 136.
  - complex, differentiation of antiblack-tongue and P-P factors from lactoflavine and vitamin B<sub>6</sub>, 423.
  - complex in animal tissues, nutritive value, U.S.D.A. 716.
  - complex, nonidentity of vitamin B<sub>6</sub> and pellagra-preventive factor, 136.
  - concentrate for prevention of black-tongue in dogs, 728.
  - concentrate, preparation from brewers' yeast, 743.
  - concentrates, growth-promoting properties when fed to rats, 728.
  - deficiency, effect on blood concentration and tissue enzymes, Ark. 716.
  - deficiency, two types of skin lesion in, relation to deficiency of flavin and vitamin B<sub>6</sub>, 426.
  - determination, accuracy of rat growth method, 277.
  - in alfalfa hay, Colo. 518.
  - in beans, green string, Tenn. 125.
  - in beef and pork, effect of cooking and canning, 422.
  - in beer, 885.
  - in body tissues of rats, 132.
  - in cabbage, green and white, Tenn. 125.
  - in coccidian infection, 691.
  - in dried distillers' grains, U.S.D.A. 716.

## Vitamin G—Continued.

- in eggs, effect of ration of hen, 677.
- in hay and grasses, effect of stage of maturity, Ohio 371.
- in human urine, 885.
- in nuts, U.S.D.A. 716.
- in peas, green, Tenn. 125.
- in sweetpotatoes, Tenn. 125.
- relation to hatchability of eggs, 677.
- requirements of poultry, [N.Y.]Cornell 378, 835; Ohio 523.
- studies, 186, 676.

## Vitamin K—

- determination, 585.
- occurrence and chemical nature, 585.
- purification, 581.

## Vitamins—

- and other dietary constituents, interrelation, 422.
- catalytic destruction by manganese during pasteurization, 527.
- deficiency—*see also* Avitaminosis and specific vitamins.
  - early recognition, 573.
  - in prescription diets of diabetics, 729.
  - relation to celiac disease of children, 889.
- in mangoes, 717.
- relation to dermatitis in chicks and turkeys, Calif. 885.
- supplements for brood sows, [N.Y.]Cornell 835.

## Vole, bank, reproduction in, 319.

## Wagon tongue, telescoping, description, 701

## Walls, retaining, pretest shoring of, 402.

## Walnut—

- dehydrator, brown type multistage, 406
- kernels, nitrogen gas as preservative, W.Va. 790
- little leaf, zinc for, Calif. 803.
- oil, studies, U.S.D.A. 579.

## Walnuts—

- breeding new varieties, Calif. 790.
- ethylene treatment and dehydration, Calif. 857.
- loosening hulls, U.S.D.A. 579.
- Persian, fertilization, Calif. 790.

## Washing—

- effect on strength of unweighted and of tin weighted silks, 891.
- technology, 574.

## Washington College, notes, 142, 287, 896.

## Washington Station, notes, 142, 287, 735, 896.

## Wasps—

- of genus *Dacynutilla*, revision, 869.
- parasitic, of subfamily Euphorinae, synonymy, classification, and key, U.S.D.A. 79.

## Wastes—

- agricultural and industrial, analyses, N.Y.State 4.
- farm, utilization, U.S.D.A. 579.
- industrial, in New Jersey, N.J. 550.

## Wasting disease, diagnosis, prevention, and treatment, 259.

## Water—

- absorption rate, effect of range plant cover, 191.
- analysis, bacteriological methods, Mich. 579.
- artesian, in Florida peninsula, 543.
- bound, in bread making, 437.
- bound, in sap and tissue, 765.
- conservation studies, Calif. 857.
- examination, standard methods, 293.
- flow around 180-degree bends, U.S.D.A. 399.
- hard, effect on metabolism in experiments with ruminants, 671.
- heating by solar energy, Calif. 550.
- in ducts and tracheids, state of, 805.
- iodine in, Ky. 130.
- lifting devices for irrigation, Mont. 400.
- of high fluorine content, source, Ariz. 109.
- reservoirs, development on the range, Mont. 699.
- resources and hydrologic investigations in British Columbia, 109.
- resources in Arizona, Graham County, 857.
- resources of Edwards limestone in San Antonio area, 253.
- resources of Elizabeth City area, North Carolina, 252.
- resources of Kleberg County, Texas, 543.
- resources of Uvalde and Medina Counties, Texas, 253.
- saline and alkaline, drinking, paths of excretion and mineral balance in animals, 84.
- stage recorder, Bristol, construction and installation, instructions, U.S.D.A. 400.

- varieties, resistant to hessian fly, Mo. 655.
- varieties, response to different fertility levels, 35.
- variety tests, Ariz. 29; Ark. 617; Ky. 29; Mo. 618; Tenn. 29; Tex. 468.
- variety tests, margin effect in, 26.
- vernalization experiments, 27.
- weight per bushel, relation to its seed value, 787.
- winter, breeding for tolerance to acid soil and low coumarin content, W.Va. 781.
- winter, cold resistance, factors affecting, 475.
- winter, cultural methods on non-irrigated lands in northeastern Wyoming, Wyo. 474.
- winter, drill survey, N.Y.State 624.
- world, survey and outlook, 867.
- world, utilization since 1885-86, 868.
- yellow rust, varietal resistance, 343, 809.
- yield and protein content, relation to weather, 444.
- yield and weather in western Canada, 587.
- yield, effect of winter soil-conserving crops, U.S.D.A. 324.
- yield, effects of summer soil-conserving crops on, U.S.D.A. 323.

- Wheatgrass, crested—**  
for pasture and production of seed under irrigation, Mont. 618.  
germination, 787.  
in Montana, Mont. 181.
- Whey—**  
cream, processing, pasteurizing difficulty in, 528.  
development of wider uses for, U.S.D.A. 667.  
lactose and lactic acid in, 388.  
powder and whey cream, use in preparation of food products, U.S.D.A. 528.  
use in producing lactic acid, U.S.D.A. 528.
- White ants, see Termites.**
- White grubs—**  
control, [N.Y.]Cornell 820.  
injury to farm crops, Ky. 65.  
role in cotton wilt transmission, 809.
- White pine blister rust—see also Ribes eradication.**  
control, U.S.D.A. 634.
- White pine—**  
eastern, thinning and management in New Hampshire, 484.  
plantations, first thinning, 338.  
seed, germination, Mich. 633.  
seedlings, total yield of roots and shoots, relation to solar radiation, 802.  
weevil, control, 826.  
western, and associated species, initial establishment, 483.  
western, stand improvement measures, U.S.D.A. 484.
- Whitefly—**  
citrus, in lower Rio Grande Valley, 507.  
rhododendron, control, oil spray tests, 507.  
rhododendron, distribution in British Columbia, life history and control, 656.
- Wild fowling, development of nonpoisonous shot for, U.S.D.A. 500.**
- Wildlife—**  
disease and population cycles research, 898.  
food habits, U.S.D.A. 500.  
management, U.S.D.A. 355, 356.  
plants utilized by, U.S.D.A. 600.  
protection, officials and organizations concerned with, U.S.D.A. 356.  
refuges, U.S.D.A. 500.  
regional types of response to sunspot cycle, 398.  
research in Wisconsin, 821.  
restoration and conservation, proceedings of North American Conference on, U.S.D.A. 354.  
Review, U.S.D.A. 651.  
status and distribution, U.S.D.A. 500.  
technology, U.S.D.A. 356.
- Wind, dissemination of aphids by, 803.**
- Windbreaks, see Trees, shelterbelt.**
- Wine—**  
making, important factors in, Calif. 740.  
making, microbiology, 299.  
new, precipitation of cream of tartar from, 745.  
New York State, pasteurization, 745.  
pasteurization, 800.  
refrigeration and spoilage, Calif. 740.  
Sauterne, bottled, preservation, 800.  
sparkling Burgundy, manufacture, 745.  
studies, U.S.D.A. 579.  
sweet, spoilage, 800.
- Winery wastes, utilization, Calif. 740.**
- Winter tick, notes, Tex. 502.**
- Wireworm—**  
infestations, fluctuations under variety of crop rotations, U.S.D.A. 666.  
pupae, destruction by plowing, U.S.D.A. 665.
- Wireworms—**  
control by flooding, 367.  
injurious to tobacco plants, Ky. 65.  
injury to potato tubers, [N.Y.]Cornell 820.  
notes, U.S.D.A. 654.  
relation to soil utilization, 77.
- Wisconsin University, notes, 735.**
- Wisconsin's human and physical resources, 125.**
- Witchweed, description and hosts, 639.**
- Woburn Experimental Station—**  
fifty years of field experiments, editorial, 433.  
fifty years of field experiments, treatise, 575.
- Wohlfahrtia vigil, behavior, 364.**
- Wolves, trapping in Alaska, U.S.D.A. 356.**
- Women—**  
metabolism during reproductive cycle, 181.  
older, basal metabolism, Ohio 419.
- Wood—see also Lumber and Timber.**  
chemical seasoning, U.S.D.A. 632.  
effectiveness of paint as protective coatings, 256; U.S.D.A. 254.  
movement of liquids in, 765.  
plastic, producing, U.S.D.A. 632.  
protecting against fungus invasion, methods and results, 650.  
quality, effect of growth conditions, U.S.D.A. 632.  
specific gravity and calorific value, effect of decay, 700.  
white rots, chemistry, 819.
- Woodcock, American, monographic account, 211.**
- Woodlands—**  
farm, management and use, U.S.D.A. 402.  
light climate, 444.
- Woods—**  
big, of Minnesota, structure and relation to climate, 45.  
Canadian, properties and uses, 193.  
use for telephone poles, Tex. 483.

## Woody—

- cuttings, transport of root-forming hormone in, 334.
- plants, native, of United States, handbook, U.S.D.A. 810.
- tissues, staining of mycelium in, 635, 807.

## Wool—

- chlorinated, acid and alkaline degradation, 139.
- cross sections and length and crimp, development of apparatus for studies, U.S.D.A. 667.
- damage due to scale breakage, measuring, 893.
- fabrics, stretch and slippage of yarns in, causes, 430.
- fineness, relation to age of animals, Tex. 516.
- growth, effect of phosphorus and other minerals, 372.
- keratin, acid degradation, 139.
- keratin, alkaline degradation, 140.
- keratin, degradation by steam, 140.
- Merino, growth and quality, factors affecting, Ohio 85
- Merino, production, effect of pregnancy and lactation, 86.
- of Texas, grades and shrinkages, Tex 516.

Wound cambial activity, 766.

Wyoming Station publications, index, Wyo 431.

## Xanthophyll—

- and carotene, determination by single distribution between liquid phases, 585.
- in leaf extract, spectrophotometric determination, 296.

*Xenopsylla cheopis*, see Rat flea, oriental.

## X-rays—

- for identification of clay substance of soils, 591.
- inactivation of tobacco mosaic virus by, 191

*Xylomites cyanoideoides*, description, 13.

Xyloporosis in limes, causes and prevention, 817.

## Yaks—

- and cattle hybrids, structure of testes, 774.
- and horned cattle hybrids, blood elements in, 176.
- chromosome numbers, 774.

Yarns, stretch and slippage in wool and silk fabrics, causes, 430.

## Yeast—

- alcoholic extraction, growth effect of residue, 564.
- cells and *Paramecium*, interaction between, 213.
- species, effect of crystallized hormones on growth, 17.
- studies, Mich. 579.

Yeasts, identification, N.Y.State 579.

Young men in farming, 877.

Youth, rural, in United States, U.S.D.A. 125.

*Yucca* species, characters and chromosome numbers, 22.

## Zinc—

- arsenate in codling moth control, Mich 655.
- arsenate, spraying tests, Mo 656.
- in soils, relation to pecan rosette, 209
- lime mixture, effect on orange mottle leaf, 352.
- role in plant nutrition, 459.
- sulfate for control of citrus mottle leaf, 817.
- sulfate, reaction with soil, Fla. 11.

Zoning ordinances, rural county, enactment and administration, 407.

*Zostera marina*, condition in Buttermilk Bay, Mass., U.S.D.A. 194.

*Zygocaccharomyces pini*, new species of yeast associated with bark beetles in pines, 462.
